453Y Further exercises (a) Let $(Y, \mathfrak{S}, \mathrm{T}, \nu)$ be a Radon measure space such that $\nu Y > 0$ and whenever $(X, \mathfrak{T}, \Sigma, \mu)$ is a Radon measure space and $f : X \to Y$ is an almost continuous inverse-measure-preserving function, then there is a disintegration $\langle \mu_y \rangle_{y \in Y}$ of μ over ν such that $\mu_y f^{-1}[\{y\}] = 1$ for almost every y. Show that ν has an almost strong lifting. (*Hint*: Start with the case in which Y is compact. Take $f : X \to Y$ to be the function described in 415R, 416V and 453Mb. Set $\underline{\phi}E = \{y : \mu_y E^* = \mu_y X = 1\}$.)

453Z Problems (a) If $(X, \mathfrak{T}, \Sigma, \mu)$ and $(Y, \mathfrak{S}, \mathrm{T}, \nu)$ are compact Radon measure spaces with strong liftings, does their product necessarily have a strong lifting? What if they are both Stone spaces?

(b) If $(X, \mathfrak{T}, \Sigma, \mu)$ is a Radon probability space with countable Maharam type, must it have an almost strong lifting?

453 Notes and comments As I noted in §452, early theorems on disintegrations concentrated on cases in which all the measure spaces involved were 'standard' in that the measures were defined on standard Borel spaces (§424), or were the completions of such measures. Under these conditions the distinction between 452I and 453K becomes blurred; measures (when completed) have to be Radon measures (433Cb), liftings have to be almost strong (453F) and disintegrations have to be concentrated on fibers (452Gc). Theorem 453K provides disintegrations concentrated on fibers without any limitation on the size of the spaces involved, though making strong topological assumptions.

The strength of 453K derives from the remarkable variety of the (Radon) measure spaces which have strong liftings, as in 453F, 453G, 453I and 453J. For some ten years there were hopes that every self-supporting Radon measure had an strong lifting, which were finally dashed by Losert 79; I give a version of the example in 453N. This is a special construction, and it remains unclear whether some much more direct approach might yield another example (453Za). I should perhaps remark straight away that if the continuum hypothesis is true, then any self-supporting Radon measure space of Maharam type at most ω_1 has a strong lifting; I will present the argument in Volume 5. In particular, subject to the continuum hypothesis, $Z \times Z$ has a strong lifting, where Z is the Stone space of the Lebesgue measure algebra, and we have a positive answer to 453Zb.

454 Measures on product spaces

A central concern of probability theory is the study of 'processes', that is, families $\langle X_t \rangle_{t \in T}$ of random variables thought of as representing the evolution of a system in time. The representation of such processes as random variables in the modern sense, that is, measurable functions on an abstract probability space, was one of the first challenges faced by Kolmogorov. In this section I give a version of Kolmogorov's theorem on the extension of consistent families of measures on subproducts to a measure on the whole product (454D). It turns out that some restriction on the marginal measures is necessary, and 'perfectness' seems to be an appropriate hypothesis, necessarily satisfied if the factor spaces are standard Borel spaces or the marginal measures are Radon measures. If we have marginal measures with stronger properties then we shall be able to infer corresponding properties of the measure on the product space (454A, generalizing 451J).

The apparatus here makes it easy to describe joint distributions of arbitrary families of real-valued random variables (454J-454M), extending the ideas of §271. For the sake of the theorem that almost all Brownian paths are continuous (455D) I briefly investigate measures on $C(T)$, where T is a Polish space (454N-454P).

454A Theorem Let $\langle (X_i, \Sigma_i, \mu_i) \rangle_{i \in I}$ be a non-empty family of totally finite measure spaces. Set $X = \prod_{i \in I} X_i$ and let μ be a measure on X which is inner regular with respect to the σ-algebra $\widehat{\bigotimes}_{i \in I} \Sigma_i$ generated by $\{\pi_i^{-1}[E] : i \in I, E \in \Sigma_i\}$, where $\pi_i : X \to X_i$ is the coordinate map for each $i \in I$. Suppose that every π_i is inverse-measure-preserving.

(a) If $\mathcal{K} \subseteq \mathcal{P}X$ is a family of sets which is closed under finite unions and countable intersections, and μ_i is inner regular with respect to $\mathcal{K}_i = \{K : K \subseteq X_i, \pi_i^{-1}[K] \in \mathcal{K}\}$ for every $i \in I$, then μ is inner regular with respect to $\mathcal{K}$.

(b)(i) If every μ_i is a compact measure, so is μ;

(ii) if every μ_i is a countably compact measure, so is μ;

(iii) if every μ_i is a perfect measure, so is μ.

proof If X is empty this is all trivial, so we may suppose that $X \neq \emptyset$.

(a) Set $\mathcal{A} = \{\pi_i^{-1}[E] : i \in I, E \in \Sigma_i\}$. If $A \in \mathcal{A}$, $V \in \Sigma$ and $\mu(A \cap V) > 0$, there is a $K \in \mathcal{K} \cap \mathcal{A}$ such that $K \subseteq A$ and $\mu(K \cap V) > 0$. **P** Express A as $\pi_i^{-1}[E]$, where $E \in \Sigma_i$; take $L \in \mathcal{K}_i$ such that $L \subseteq E$ and $\mu_i L > \mu_i E - \mu(A \cap V)$, and set $K = \pi_i^{-1}[L]$. **Q**

By 412C, $\mu\restriction\widehat{\bigotimes}_{i\in I}\Sigma_i$ is inner regular with respect to $\mathcal{K}$; by 412Ab, so is μ.

(b)(i)-(ii) Suppose that every μ_i is (countably) compact. Then for each $i \in I$ we can find a (countably) compact class $\mathcal{K}_i \subseteq \mathcal{P}X_i$ such that μ_i is inner regular with respect to $\mathcal{K}_i$. Set $\mathcal{L} = \{\pi_i^{-1}[K] : i \in I, K \in \mathcal{K}_i\}$. Then $\mathcal{L}$ is (countably) compact (451H). So there is a (countably) compact $\mathcal{K} \supseteq \mathcal{L}$ which is closed under finite unions and countable intersections (342D, 413R). Now μ is inner regular with respect to $\mathcal{K}$, by (a), and therefore (countably) compact.

(iii) Let T_0 be a countably generated σ-subalgebra of $\widehat{\bigotimes}_{i\in I}\Sigma_i$. Then there must be some countable subfamily $\mathcal{E}$ of $\{\pi_i^{-1}[E] : i \in I, E \in \Sigma_i\}$ such that T_0 is included in the σ-algebra generated by $\mathcal{E}$ (use 331Gd). Set $\mathcal{E}_i = \{E : E \in \Sigma_i, \pi_i^{-1}[E] \in \mathcal{E}\}$ for each i, so that $\mathcal{E}_i$ is countable, and let Σ_i' be the σ-algebra generated by $\mathcal{E}_i$. Then $\mu_i\restriction\Sigma_i'$ is compact (451F). Applying (i), we see that $\mu\restriction\widehat{\bigotimes}_{i\in I}\Sigma_i'$ is compact, therefore perfect; while $\mathrm{T}_0 \subseteq \widehat{\bigotimes}_{i\in I}\Sigma_i'$. As T_0 is arbitrary, $\mu\restriction\widehat{\bigotimes}_{i\in I}\Sigma_i$ is perfect (451F). But as the completion of μ is exactly the completion of $\mu\restriction\widehat{\bigotimes}_{i\in I}\Sigma_i$, μ also is perfect, by 451Gc.

454B Corollary Let $\langle X_i\rangle_{i\in I}$ be a family of Polish spaces with product X. Then any totally finite Baire measure on X is a compact measure.

proof If μ is a Baire measure on X, then its domain $\mathcal{B}\mathfrak{a}(X)$ is $\widehat{\bigotimes}_{i\in I}\mathcal{B}(X_i)$, where $\mathcal{B}(X_i)$ is the Borel σ-algebra of X_i for each $i \in I$ (4A3Na). So each image measure μ_i on X_i is a Borel measure, therefore tight (that is, inner regular with respect to the compact sets, 433Ca), and by 454A(b-i) μ is compact.

454C Theorem(Marczewski & Ryll-Nardzewski 53) Let (X, Σ, μ) be a perfect totally finite measure space and (Y, T, ν) any totally finite measure space. Let $\Sigma \otimes \mathrm{T}$ be the algebra of subsets of $X \times Y$ generated by $\{E \times F : E \in \Sigma, F \in \mathrm{T}\}$. If $\lambda_0 : \Sigma \otimes \mathrm{T} \to [0, \infty[$ is a non-negative finitely additive functional such that $\lambda_0(E\times Y) = \mu E$ and $\lambda_0(X \times F) = \nu F$ whenever $E \in \Sigma$ and $F \in \mathrm{T}$, then λ_0 has a unique extension to a measure defined on the σ-algebra $\Sigma\widehat{\otimes}\mathrm{T}$ generated by $\Sigma \otimes \mathrm{T}$.

proof (a) By 413K, it will be enough to show that $\lim_{n\to\infty}\lambda_0 W_n = 0$ for every non-increasing sequence $\langle W_n\rangle_{n\in\mathbb{N}}$ in $\Sigma \otimes \mathrm{T}$ with empty intersection. Take such a sequence. Each W_n must belong to the algebra generated by some finite subset of $\{E \times F : E \in \Sigma, F \in \mathrm{T}\}$, so there must be a countable set $\mathcal{E} \subseteq \Sigma$ such that every W_n belongs to the algebra generated by $\{E \times F : E \in \mathcal{E}, F \in \mathrm{T}\}$; let Σ_0 be the σ-subalgebra of Σ generated by $\mathcal{E}$, so that every W_n belongs to $\Sigma_0\widehat{\otimes}\mathrm{T}$.

(b) By 451F, $\mu\restriction\Sigma_0$ is a compact measure; let $\mathcal{K} \subseteq \mathcal{P}X$ be a compact class such that $\mu\restriction\Sigma_0$ is inner regular with respect to $\mathcal{K}$. We may suppose that $\mathcal{K}$ is the family of closed sets for a compact topology on X (342Da). Let $\mathcal{W}$ be the family of those elements W of $\Sigma_0 \otimes \mathrm{T}$ such that every horizontal section $W^{-1}[\{y\}]$ belongs to $\mathcal{K}$. Then $\mathcal{W}$ is closed under finite unions and intersections.

(c) If $W \in \Sigma_0 \otimes \mathrm{T}$ and $\epsilon > 0$, then there is a $W' \in \mathcal{W}$ such that $W' \subseteq W$ and $\lambda_0(W \setminus W') \leq \epsilon$. **P** Express W as $\bigcup_{i\leq n} E_i \times F_i$, where $E_i \in \Sigma_0$, $F_i \in \mathrm{T}$ for each $i \leq n$. (Cf. 315Jb.) For each $i \leq n$, take $K_i \in \mathcal{K} \cap \Sigma_0$ such that $\mu(E_i \setminus K_i) \leq \frac{1}{n+1}\epsilon$, and set $W' = \bigcup_{i\leq n} K_i \times F_i$. Then $W' \in \mathcal{W}$, $W' \subseteq W$ and

$$\begin{aligned}\lambda_0(W \setminus W') &\leq \sum_{i=0}^{n} \lambda_0((E_i \times F_i) \setminus (K_i \times F_i)) \leq \sum_{i=0}^{n} \lambda_0((E_i \setminus K_i) \times Y)\\ &= \sum_{i=0}^{n} \mu_0(E_i \setminus K_i) \leq \epsilon.\end{aligned}$$ **Q**

(d) Take any $\epsilon > 0$. Then for each $n \in \mathbb{N}$ we can find $W_n' \in \mathcal{W}$ such that $W_n' \subseteq W_n$ and $\lambda_0(W_n \setminus W_n') \leq 2^{-n}\epsilon$. Set $V_n = \bigcap_{i\leq n} W_i'$, so that $V_n \in \mathcal{W}$ and

$$\lambda_0(W_n \setminus V_n) \leq \textstyle\sum_{i=0}^{n} \lambda_0(W_i \setminus W_i') \leq 2\epsilon$$

for each n, and $\langle V_n\rangle_{n\in\mathbb{N}}$ is non-increasing, with empty intersection.

Because $V_n \in \Sigma_0 \otimes \mathrm{T}$, its projection $H_n = V_n[X]$ belongs to T, for each n. Of course $\langle H_n\rangle_{n\in\mathbb{N}}$ is non-increasing; also $\bigcap_{n\in\mathbb{N}} H_n = \emptyset$. **P** If $y \in Y$, then $\langle V_n^{-1}[\{y\}]\rangle_{n\in\mathbb{N}}$ is a non-increasing sequence in $\mathcal{K}$ with

empty intersection, because $\bigcap_{n\in\mathbb{N}} V_n \subseteq \bigcap_{n\in\mathbb{N}} W_n$ is empty. But $\mathcal{K}$ is a compact class, so there must be some n such that $V_n^{-1}[\{y\}]$ is empty, that is, $y \notin H_n$. **Q** Accordingly $\lim_{n\to\infty} \nu H_n = 0$. But as $V_n \subseteq X \times H_n$, $\lim_{n\to\infty} \lambda_0 V_n = 0$.

This means that $\lim_{n\to\infty} \lambda_0 W_n \leq 2\epsilon$. But as ϵ is arbitrary, $\lim_{n\to\infty} \lambda_0 W_n = 0$, as required.

454D Theorem (KOLMOGOROV 33, §III.4) Let $\langle (X_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a family of totally finite perfect measure spaces. Set $X = \prod_{i\in I} X_i$, and write $\bigotimes_{i\in I} \Sigma_i$ for the algebra of subsets of X generated by $\{\pi_i^{-1}[E] : i \in I, E \in \Sigma_i\}$, where $\pi_i : X \to X_i$ is the coordinate map for each $i \in I$. Suppose that $\lambda_0 : \bigotimes_{i\in I} \Sigma_i \to [0,\infty[$ is a non-negative finitely additive functional such that $\lambda_0 \pi_i^{-1}[E] = \mu_i E$ whenever $i \in I$ and $E \in \Sigma_i$. Then λ_0 has a unique extension to a measure λ with domain $\widehat{\bigotimes}_{i\in I}\Sigma_i$, and λ is perfect.

proof (a) The argument follows the same pattern as that of 454C. This time, take a non-increasing sequence $\langle W_n\rangle_{n\in\mathbb{N}}$ in $\bigotimes_{i\in I} \Sigma_i$ with empty intersection. Each W_n belongs to the algebra generated by some finite subset of $\{\pi_i^{-1}[E] : i \in I, E \in \Sigma_i\}$, so we can find countable sets $\mathcal{E}_i \subseteq \Sigma_i$ such that every W_n belongs to the subalgebra generated by $\{\pi_i^{-1}[E] : i \in I, E \in \mathcal{E}_i\}$. Let T_i be the σ-subalgebra of Σ_i generated by $\mathcal{E}_i$, so that every W_n belongs to $\bigotimes_{i\in I} \mathrm{T}_i$.

(b) For each $i \in I$, $\mu_i \restriction \mathrm{T}_i$ is compact (451F); let $\mathfrak{T}_i$ be a compact topology on X_i such that $\mu_i \restriction \mathrm{T}_i$ is inner regular with respect to the closed sets (342F). Let $\mathfrak{T}$ be the product topology on X, so that $\mathfrak{T}$ is compact (3A3J). Let $\mathcal{W}$ be the family of closed sets in X belonging to $\bigotimes_{i\in I} \mathrm{T}_i$.

(c) If $W \in \bigotimes_{i\in I} \mathrm{T}_i$ and $\epsilon > 0$, there is a $W' \in \mathcal{W}$ such that $W' \subseteq W$ and $\lambda_0(W \setminus W') \leq \epsilon$. **P** We can express W as $\bigcup_{k\leq n} \bigcap_{i\in J_k} \pi_i^{-1}[E_{ki}]$ where each J_k is a finite subset of I and $E_{ki} \in \Sigma_i$ for $k \leq n$, $i \in J_k$ (cf. 315Jb). Let $\langle \epsilon_{ki}\rangle_{k\leq n, i\in J_k}$ be a family of strictly positive numbers with sum at most ϵ. For each $k \leq n$, $i \in J_k$ take $K_{ki} \in \mathcal{K}_i \cap \mathrm{T}_i$ such that $K_{ki} \subseteq E_{ki}$ and $\mu_i(E_{ki} \setminus K_{ki}) \leq \epsilon_{ki}$, and set $W' = \bigcup_{k\leq n} \bigcap_{i\in J_k} \pi_i^{-1}[K_{ki}]$. **Q**

(d) Take any $\epsilon > 0$. Then for each $n \in \mathbb{N}$ we can find $W_n' \in \mathcal{W}$ such that $W_n' \subseteq W_n$ and $\lambda_0(W_n \setminus W_n') \leq 2^{-n}\epsilon$. Set $V_n = \bigcap_{i\leq n} W_i'$. Then $\langle V_n\rangle_{n\in\mathbb{N}}$ is a non-increasing sequence of closed sets in the compact space X, and has empty intersection, so there is some n such that V_n is empty, and

$$\lambda_0 W_n \leq \textstyle\sum_{i=0}^{n} \lambda_0(W_i \setminus W_i') \leq 2\epsilon.$$

As ϵ is arbitrary, $\lim_{n\to\infty} \lambda_0 W_n = 0$.

(e) As $\langle W_n\rangle_{n\in\mathbb{N}}$ is arbitrary, λ_0 has a unique countably additive extension to $\widehat{\bigotimes}_{i\in I}\Sigma_i$, by 413K, as before. Of course the extension is perfect, by 454A(b-iii).

454E Corollary Let $\langle (X_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a family of perfect measure spaces. Let $\mathcal{C}$ be the family of subsets of $X = \prod_{i\in I} X_i$ expressible in the form $X \cap \bigcap_{i\in J} \pi_i^{-1}[E_i]$ where $J \subseteq I$ is finite and $E_i \in \Sigma_i$ for every $i \in I$, writing $\pi_i(x) = x(i)$ for $x \in X$, $i \in I$. Suppose that $\lambda_0 : \mathcal{C} \to \mathbb{R}$ is a functional such that (i) $\lambda_0 \pi_i^{-1}[E] = \mu_i E$ whenever $i \in I$ and $E \in \Sigma_i$ (ii) $\lambda_0 C = \lambda_0(C \cap \pi_i^{-1}[E]) + \lambda_0(C \setminus \pi_i^{-1}[E])$ whenever $C \in \mathcal{C}$, $i \in I$ and $E \in \Sigma_i$. Then λ_0 has a unique extension to a measure on $\widehat{\bigotimes}_{i\in I}\Sigma_i$, which is necessarily perfect.

proof By 326Q, λ_0 has an extension to an additive functional on $\bigotimes_{i\in I} \Sigma_i$, so we can apply 454D.

454F Corollary Let $\langle (X_i, \Sigma_i)\rangle_{i\in I}$ be a family of standard Borel spaces. Set $X = \prod_{i\in I} X_i$, and let $\bigotimes_{i\in I} \Sigma_i$ be the algebra of subsets of X generated by $\{\pi_i^{-1}[E] : i \in I, E \in \Sigma_i\}$, where $\pi_i : X \to X_i$ is the coordinate map for each i. Let $\lambda_0 : \Sigma \to [0,\infty[$ be a non-negative finitely additive functional such that all the marginal functionals $E \mapsto \lambda_0 \pi_i^{-1}[E] : \Sigma_i \to [0,\infty[$ are countably additive. Then λ_0 has a unique extension to a measure defined on $\widehat{\bigotimes}_{i\in I}\Sigma_i$, which is a compact measure.

proof This follows immediately from 454D and 454A if we note that all the measures $\lambda_0 \pi_i^{-1}$ are necessarily compact, therefore perfect (451L).

454G Corollary Let $\langle X_i\rangle_{i\in I}$ be a family of sets, and Σ_i a σ-algebra of subsets of X_i for each $i \in I$. Suppose that for each finite set $J \subseteq I$ we are given a totally finite measure μ_J on $Z_J = \prod_{i\in J} X_i$ with domain $\widehat{\bigotimes}_{i\in J}\Sigma_i$ such that (i) whenever J, K are finite subsets of I and $J \subseteq K$, then the canonical projection from Z_K to Z_J is inverse-measure-preserving (ii) every marginal measure $\mu_{\{i\}}$ on $Z_{\{i\}} \cong X_i$ is perfect. Then there is a unique measure μ defined on $\widehat{\bigotimes}_{i\in I}\Sigma_i$ such that the canonical projection $\tilde\pi_J : \prod_{i\in I} X_i \to Z_J$ is inverse-measure-preserving for every finite $J \subseteq I$.

proof All we need to observe is that

$$\textstyle\bigotimes_{i\in I}\Sigma_i = \{\tilde\pi_J^{-1}[V] : J \in [I]^{<\omega},\ V \in \bigotimes_{i\in J}\Sigma_i\}.$$

Because all the canonical projections from X_K onto X_J are inverse-measure-preserving, we have $\mu_J V = \mu_K V'$ whenever J, K are finite subsets of I, $V \in \bigotimes_{i\in J}\Sigma_i$, $V' \in \bigotimes_{i\in K}\Sigma_i$ and $\tilde\pi_J^{-1}[V] = \tilde\pi_K^{-1}[V']$. So we have a functional $\lambda_0 : \bigotimes_{i\in I}\Sigma_i \to [0,\infty[$ such that $\lambda_0\tilde\pi_J^{-1}[V] = \mu_J V$ whenever $J \subseteq I$ is finite and $V \in \bigotimes_{i\in J}\Sigma_i$. It is easy to check that λ_0 is finitely additive and satisfies the conditions of 454D. So λ_0 can be extended to a measure μ defined on $\widehat{\bigotimes}_{i\in I}\Sigma_i$.

If $J \subseteq I$ is finite, then μ_J and $\mu\tilde\pi_J^{-1}$ agree on $\bigotimes_{i\in J}\Sigma_J$ and therefore (by the Monotone Class Theorem, 136C) on $\widehat{\bigotimes}_{i\in J}\Sigma_i$; that is, $\tilde\pi_J$ is inverse-measure-preserving. To see that μ itself is unique, observe that the conditions define its values on $\bigotimes_{i\in I}\Sigma_i$ and therefore on $\widehat{\bigotimes}_{i\in I}\Sigma_i$, by the Monotone Class Theorem once more.

454H Corollary Let $\langle(X_n,\Sigma_n)\rangle_{n\in\mathbb{N}}$ be a sequence of standard Borel spaces. For each $n \in \mathbb{N}$ set $Z_n = \prod_{i<n} X_i$, $\mathrm{T}_n = \widehat{\bigotimes}_{i<n}\Sigma_i$. (For $n = 0$, we have $Z_0 = \{\emptyset\}$, $\mathrm{T}_0 = \{\emptyset, Z_0\}$.) For $n \in \mathbb{N}$, $W \in \mathrm{T}_{n+1}$, $z \in Z_n$ write $W[\{z\}] = \{\xi : \xi \in X_n, (z,\xi) \in W\}$; set $X = \prod_{n\in\mathbb{N}} X_n$ and write $\tilde\pi_n$ for the canonical projection of X onto Z_n. Suppose that for each $n \in \mathbb{N}$ and $z \in Z_n$ we are given a probability measure ν_z on X_n with domain Σ_n such that $z \mapsto \nu_z(E)$ is T_n-measurable for every $E \in \Sigma_n$. Then there is a unique probability measure μ on $X = \prod_{n\in\mathbb{N}} X_n$, with domain $\Sigma = \widehat{\bigotimes}_{n\in\mathbb{N}}\Sigma_n$, such that, writing $\tilde\mu_n$ for the image measure $\mu\tilde\pi_n^{-1}$ on Z_n,

$$\tilde\mu_{n+1}(W) = \textstyle\int \nu_z W[\{z\}]\tilde\mu_n(dz)$$

for every $n \in \mathbb{N}$ and $W \in \mathrm{T}_{n+1}$, and

$$\textstyle\int f d\tilde\mu_{n+1} = \iint \dots \iint f(\xi_0,\dots,\xi_n)\nu_{(\xi_0,\dots,\xi_{n-1})}(d\xi_n)$$
$$\nu_{(\xi_0,\dots,\xi_{n-2})}(d\xi_{n-1})\dots\nu_{\xi_0}(d\xi_1)\nu_\emptyset(d\xi_0)$$

for every $n \in \mathbb{N}$ and $\tilde\mu_{n+1}$-integrable real-valued function f.

proof (a) We must check that the first formula given actually defines $\tilde\mu_{n+1}(W)$ for every $W \in \mathrm{T}_{n+1}$. Of course this is an induction on n. $\tilde\mu_0$ will be the unique probability measure on the singleton set Z_0. Given that $\operatorname{dom}\tilde\mu_n = \mathrm{T}_n$, the class $\mathcal{W}$ of sets $W \subseteq Z_{n+1}$ for which $\int \nu_z W[\{z\}]\tilde\mu_n(dz)$ is defined will contain all sets of the form $\prod_{i\le n} E_i$ where $E_i \in \Sigma_i$ for every $i \le n$, just because the function $z \mapsto \nu_z E_n$ is T_n-measurable. Since $\mathcal{W}$ is closed under increasing sequential unions and differences of comparable sets, the Monotone Class Theorem (136B) tells us that it includes the σ-algebra generated by the cylinder sets, which is T_{n+1}.

(b) Accordingly $\langle\nu'_z\rangle_{z\in Z_n}$ is a disintegration of $\tilde\mu_{n+1}$ over $\tilde\mu_n$, where ν'_z is the measure with domain T_{n+1} defined by writing $\nu'_z(W) = \nu_z W[\{z\}]$ for $W \in \mathrm{T}_{n+1}$, $z \in Z_n$. By 452F,

$$\begin{aligned}\int_{Z_{n+1}} f d\tilde\mu_{n+1} &= \int_{Z_n}\int_{Z_{n+1}} f(w)\nu'_z(dw)\tilde\mu_n(dz)\\ &= \int_{Z_n}\int_{X_n} f(z,\xi_{n+1})\nu_z(d\xi_{n+1})\tilde\mu_n(dz)\end{aligned}$$

for every $\tilde\mu_{n+1}$-integrable function f. (The second equality can be regarded as an application of the change-of-variable formula 235Ib applied to the (ν_z,ν'_z)-inverse-measure-preserving function $\xi \mapsto (z,\xi) : X_{n+1} \to Z_{n+1}$.) Now a direct induction yields the general formula for $\int f d\tilde\mu_{n+1}$ in the statement of this corollary.

(c) The canonical maps from Z_{n+1} to Z_n are all inverse-measure-preserving, just because every ν_z is a probability measure. We therefore have a well-defined functional $\lambda_0 : \bigotimes_{n\in\mathbb{N}} \Sigma_n \to [0,1]$ defined by setting $\lambda_0 \tilde{\pi}_n^{-1}[W] = \mu_n W$ whenever $n \in \mathbb{N}$ and $W \in \bigotimes_{i<n} \Sigma_i$, and this λ_0 is finitely additive; moreover, each marginal measure $\lambda_0 \pi_n^{-1}$, where $\pi_n : X \to X_n$ is the coordinate map, is countably additive, because it is expressible as an image measure of μ_{n+1} on X_n.

(d) Everything so far has been valid for any sequence $\langle (X_n, \Sigma_n)\rangle_{n\in\mathbb{N}}$ of sets with attached σ-algebras. But at this point we note that the marginal measures $\lambda_0 \pi_n^{-1}$ must be perfect, because (X_n, Σ_n) is a standard Borel space. So Theorem 454D gives the result.

454I Remarks In 454F and 454H the hypotheses call for 'standard Borel spaces' (X_i, Σ_i). As the proofs make clear, what is needed in each case is that 'every totally finite measure with domain Σ_i must be perfect'. We have already seen other ways in which this can be true: for instance, if X is any Radon Hausdorff space (§434), and Σ its Borel σ-algebra. Further examples are in 454Xd-454Xi and 454Yb-454Yc. Indeed, even weaker hypotheses can be fully adequate. In 454H, for instance, it will be quite enough if all the marginal measures on the factors X_n are perfect; in view of 454A and 451E, this will be so iff all the measures $\tilde{\mu}_n$ on the partial products Z_n are perfect. It may be difficult to be sure of this unless either we have some argument from the nature of the factor spaces (X_n, Σ_n), as suggested above, or a clear understanding of the marginal measures. In applications such as 455A below, however, there may be other approaches available.

454J Distributions of random processes For the next few paragraphs I shift to probabilists' notation.

Proposition Let (Ω, Σ, μ) be a probability space and $\langle X_i\rangle_{i\in I}$ a family of real-valued random variables on Ω (see §271).

(i) There is a unique complete probability measure ν on $\mathbb{R}^I$, measuring every Baire set and inner regular with respect to the zero sets, such that

$$\nu\{x : x \in \mathbb{R}^I, x(i_r) \le \alpha_r \text{ for every } r \le n) = \Pr(X_{i_r} \le \alpha_r \text{ for every } r \le n\}$$

whenever $i_0, \dots, i_n \in I$ and $\alpha_0, \dots, \alpha_n \in \mathbb{R}$.

(ii) If $i_0, \dots, i_n \in I$ and $\tilde{\pi}(x) = (x(i_0), \dots, x(i_n))$ for $x \in \mathbb{R}^I$, then the image measure $\nu\tilde{\pi}^{-1}$ on $\mathbb{R}^{n+1}$ is the joint distribution of $X_{i_0}, \dots, X_{i_n}$ as defined in 271C.

(iii) ν is a compact measure. If I is countable then ν is a Radon measure.

(iv) If every X_i is defined everywhere on Ω, then the function $\omega \mapsto \langle X_i(\omega)\rangle_{i\in I} : \Omega \to \mathbb{R}^I$ is inverse-measure-preserving for $\hat{\mu}$ and ν, where $\hat{\mu}$ is the completion of μ.

proof (a) Completing μ, and adjusting the X_i on negligible sets, does not change any of the joint distributions of families $X_{i_0}, \dots, X_{i_n}$ (271Ad), so we may suppose henceforth that μ is complete and that every X_i is defined on the whole of Ω. Set $\phi(\omega) = \langle X_i(\omega)\rangle_{i\in I}$ for $\omega \in \Omega$. Then $\{F : F \subseteq \mathbb{R}^I, \phi^{-1}[F] \in \Sigma\}$ is a σ-algebra of subsets of $\mathbb{R}^I$ containing $\{x : x(i) \le \alpha\}$ whenever $i \in I$ and $\alpha \in \mathbb{R}$, so includes the Baire σ-algebra $\mathcal{Ba}(\mathbb{R}^I)$ of $\mathbb{R}^I$ (4A3Na). If we define $\nu_0 F = \mu\phi^{-1}[F]$ for $F \in \mathcal{Ba}(\mathbb{R}^I)$, ν_0 is a Baire measure on $\mathbb{R}^I$ for which ϕ is inverse-measure-preserving. We are supposing that μ is complete, so ϕ is still inverse-measure-preserving for μ and the completion ν of ν_0 (235Hc). Since ν_0 is inner regular with respect to the zero sets (412D), so is ν (412Ha), and of course ν measures every Baire set. By 454B, ν_0 is compact, so ν also is (451Ga).

(b) If $i_0, \dots, i_n \in I$ and $\alpha_0, \dots, \alpha_n \in \mathbb{R}$, then

$$\begin{aligned}\Pr(X_{i_r} \le \alpha_r \text{ for every } r \le n) &= \mu\{\omega : X_{i_r}(\omega) \le \alpha_r \text{ for } r \le n\}\\ &= \mu\{\omega : \phi(x)(i_r) \le \alpha_r \text{ for } r \le n\}\\ &= \nu\{x : x(i_r) \le \alpha_r \text{ for } r \le n\}.\end{aligned}$$

(c) If $i_0, \dots, i_n \in I$ and we set $\tilde{\pi}(x) = (x(i_0), \dots, x(i_n))$ for $x \in \mathbb{R}^I$, then $\nu\tilde{\pi}^{-1}$ is a Radon measure (451N). Since it agrees with the distribution of $X_{i_0}, \dots, X_{i_n}$ on all sets of the form $\{z : z(r) \le \alpha_r \text{ for } r \le n\}$, it must be exactly the distribution of $X_{i_0}, \dots, X_{i_n}$ (271Ba).

(d) If I is countable, then $\mathbb{R}^I$ is Polish, so ν is a Radon measure (433Cb).

(e) The only point I have not covered is the uniqueness of ν. But suppose that ν' is another measure on $\mathbb{R}^I$ with the properties described in (i). If $i_0, \dots, i_n \in I$ and $\tilde{\pi}(x) = (x(i_0), \dots, x(i_n))$ for $x \in \mathbb{R}^I$, then the image measures $\nu\tilde{\pi}^{-1}$ and $\nu'\tilde{\pi}^{-1}$ on $\mathbb{R}^{n+1}$ are both the distribution of $X_{i_0}, \dots, X_{i_n}$, by the argument of (c) above. This means that ν and ν' agree on the algebra of subsets of $\mathbb{R}^I$ generated by sets of the form $\{x : x(i) \in E\}$ where $i \in I$ and $E \subseteq \mathbb{R}$ is Borel. By 454D, they agree on all zero sets, and must be equal (412L).

454K Definition In the context of 454J, I will call ν the (**joint**) **distribution** of the process $\langle X_i \rangle_{i \in I}$.

Note that if $I = n \in \mathbb{N} \setminus \{0\}$, then ν is a Radon measure on $\mathbb{R}^n$, so is the distribution of $\langle X_i \rangle_{i<n}$ in the sense of 271C.

454L Proposition Let (Ω, Σ, μ) be a probability space and $\langle X_i \rangle_{i \in I}$ a family of random variables on Ω, with distribution ν. If $\langle i_n \rangle_{n \in \mathbb{N}}$ is a sequence in I and $f : \mathbb{R}^{\mathbb{N}} \to \mathbb{R}$ is a Borel measurable function, then the random variables

$$\omega \mapsto f(\langle X_{i_n}(\omega) \rangle_{n \in \mathbb{N}}) : \textstyle\bigcap_{n \in \mathbb{N}} \operatorname{dom} X_{i_n} \to \mathbb{R}, \quad x \mapsto f(\langle x(i_n) \rangle_{n \in \mathbb{N}}) : \mathbb{R}^I \to \mathbb{R}$$

have the same distribution.

proof Completing μ and extending each X_i to the whole of Ω, we may suppose that $\phi : \Omega \to \mathbb{R}^I$ is inverse-measure-preserving, where $\phi(\omega) = \langle X_i(\omega) \rangle_{i \in I}$ for $\omega \in \Omega$. Now, for any $\alpha \in \mathbb{R}$,

$$\begin{aligned} \nu\{x : f(\langle x_(i_n) \rangle_{n \in \mathbb{N}}) \leq \alpha\} &= \mu\{\omega : f(\langle \phi(\omega)(i_n) \rangle_{n \in \mathbb{N}}) \leq \alpha\} \\ &= \mu\{\omega : f(\langle X_{i_n}(\omega) \rangle_{n \in \mathbb{N}}) \leq \alpha\}, \end{aligned}$$

so the distributions are the same.

454M Theorem Let I be a set.

(a) Let ν and ν' be Baire probability measures on $\mathbb{R}^I$ such that $\int e^{if(x)}\nu(dx) = \int e^{if(x)}\nu'(dx)$ for every continuous linear functional $f : \mathbb{R}^I \to \mathbb{R}$. Then $\nu = \nu'$.

(b) Let $\langle X_j \rangle_{j \in I}$ and $\langle Y_j \rangle_{j \in I}$ be two families of random variables such that

$$\mathbb{E}(\exp(i \textstyle\sum_{r=0}^n \alpha_r X_{j_r})) = \mathbb{E}(\exp(i \sum_{r=0}^n \alpha_r Y_{j_r}))$$

whenever $j_0, \dots, j_n \in I$ and $\alpha_0, \dots, \alpha_n \in \mathbb{R}$. Then $\langle X_j \rangle_{j \in I}$ and $\langle Y_j \rangle_{j \in I}$ have the same distribution.

proof (a) For each finite set $J \subseteq I$, write $\tilde{\pi}_J(x) = x \restriction J$ for $x \in X$. Then we have Radon measures μ_J and μ'_J on $\mathbb{R}^J$ defined by saying that $\mu_J F = \nu\tilde{\pi}_J^{-1}[F]$, $\mu'_J F = \nu'\tilde{\pi}_J^{-1}[F]$ for Borel sets $F \subseteq \mathbb{R}^J$. If $\langle \alpha_j \rangle_{j \in J} \in \mathbb{R}^J$, then

$$\begin{aligned} \int \exp(i \sum_{j \in J} \alpha_j z(j)) \mu_J(dz) &= \int \exp(i \sum_{j \in J} \alpha_j x(j)) \nu(dx) \\ &= \int \exp(i \sum_{j \in J} \alpha_j x(j)) \nu'(dx) = \int \exp(i \sum_{j \in J} \alpha_j z(j)) \mu'_J(dz), \end{aligned}$$

so μ_J and μ'_J have the same characteristic function, therefore are equal. This is true for every J, so ν and ν' are equal, by 454D.

(b) Taking ν and ν' to be the two distributions, (a) (with 454L) tells us that their restrictions to the Baire σ-algebra of $\mathbb{R}^I$ are the same, so they must be identical.

454N Continuous processes The original, and still by far the most important, context for 454D is when every (X_i, Σ_i) is $\mathbb{R}$ with its Borel σ-algebra, so that $X = \prod_{i \in I} X_i$ can be identified with $\mathbb{R}^I$. In the discussion so far, the set I has been an abstract set, except in the very special case of 454H. But some of the most important applications (to which I shall come in the next section) involve index sets carrying a topological structure; for instance, I could be the unit interval $[0, 1]$ or the half-line $[0, \infty[$. In such a case, we have a wide variety of subspaces of $\mathbb{R}^I$ (for instance, the space of continuous functions) marked out as

special, and it is important to know when, and in what sense, our measures on the product space $\mathbb{R}^I$ can be regarded as, or replaced by, measures on the subspace of interest. In the next few paragraphs I look briefly at spaces of continuous functions on Polish spaces.

Lemma Let T be a separable metrizable space and (X, Σ, μ) a semi-finite measure space. Let $\mathfrak{T}$ be a topology on X such that μ is inner regular with respect to the closed sets.

(a) Let $\phi : X \times T \to \mathbb{R}$ be a function such that (i) for each $x \in X$, $t \mapsto \phi(x,t)$ is continuous (ii) for each $t \in T$, $x \mapsto \phi(x,t)$ is Σ-measurable. Then μ is inner regular with respect to $\mathcal{K} = \{K : K \subseteq X, \phi\restriction K \times T \text{ is continuous}\}$.

(b) Let $\theta : X \to C(T)$ be a function such that $x \mapsto \theta(x)(t)$ is Σ-measurable for every $t \in T$. Give $C(T)$ the topology $\mathfrak{T}_c$ of uniform convergence on compact subsets of T. Then θ is almost continuous.

proof (a) Take $E \in \Sigma$ and $\gamma < \mu E$; take $F \in \Sigma$ such that $F \subseteq E$ and $\gamma < \mu F < \infty$. Let $\mathcal{U}$ be a countable base for the topology of T consisting of non-empty sets, D a countable dense subset of T and $\mathcal{V}$ a countable base for the topology of $\mathbb{R}$. For $U \in \mathcal{U}$, $V \in \mathcal{V}$ set

$$E_{UV} = \{x : \phi(x,t) \in V \text{ for every } t \in U \cap D\};$$

then $E_{UV} \in \Sigma$. Let $\langle \epsilon_{UV} \rangle_{U \in \mathcal{U}, V \in \mathcal{V}}$ be a family of strictly positive numbers with sum at most $\mu F - \gamma$. For each $U \in \mathcal{U}$, $V \in \mathcal{V}$ take a closed set $F_{UV} \subseteq F \setminus E_{UV}$ such that $\mu F_{UV} \geq \mu(F \setminus E_{UV}) - \epsilon_{UV}$. Consider

$$K = \bigcap_{U \in \mathcal{U}, V \in \mathcal{V}} F_{UV} \cup (F \cap E_{UV}).$$

Then $K \subseteq E$ and $\mu K \geq \gamma$.

If $x \in K$, $t \in T$ and $\phi(x,t) \in V_0 \in \mathcal{V}$, let $V \in \mathcal{V}$ be such that $\phi(x,t) \in V$ and $\overline{V} \subseteq V_0$. Then $\{t' : \phi(x,t') \in V\}$ is an open set containing t, so there is some $U \in \mathcal{U}$ such that $t \in U$ and $\phi(x,t') \in V$ for every $t' \in U$. This means that $x \in E_{UV}$, so that $(K \setminus F_{UV}) \times U$ contains (x,t), and is a relatively open set in $K \times T$. If $(x',t') \in (K \setminus F_{UV}) \times U$, then $x' \in E_{UV}$, so $\phi(x',t'') \in V$ whenever $t'' \in U \cap D$; as D is dense, $\phi(x',t'') \in \overline{V}$ whenever $t'' \in U$; in particular, $\phi(x',t') \in \overline{V} \subseteq V_0$. This shows that $(K \times T) \cap \phi^{-1}[V_0]$ is relatively open in $K \times T$; as V_0 is arbitrary, $\phi\restriction K \times T$ is continuous.

So $K \in \mathcal{K}$. As E and γ are arbitrary, μ is inner regular with respect to $\mathcal{K}$.

(b) Set $\phi(x,t) = \theta(x)(t)$ for $x \in X$, $t \in T$. Because $\theta(x) \in C(T)$ for every x, ϕ is continuous in the second variable; and the hypothesis on θ is just that ϕ is measurable in the first variable. So μ is inner regular with respect to $\mathcal{K}$ as described in (a). But $\theta\restriction K$ is continuous for every $K \in \mathcal{K}$, by 4A2G(g-ii). So θ is almost continuous.

454O Proposition Let T be an analytic metrizable space (e.g., a Polish space, or any Souslin-F subset of a Polish space), and μ a probability measure on $C(T)$ with domain the σ-algebra Σ generated by the evaluation functionals $f \mapsto f(t) : C(T) \to \mathbb{R}$ for $t \in T$. Give $C(T)$ the topology $\mathfrak{T}_c$ of uniform convergence on compact subsets of T. Then the completion of μ is a $\mathfrak{T}_c$-Radon measure.

proof If T is empty this is trivial, so let us suppose henceforth that $T \neq \emptyset$.

(a) Let D be a countable dense subset of T. Let $\pi : C(T) \to \mathbb{R}^D$ be the restriction map. Set $X = \pi[C(T)] \subseteq \mathbb{R}^D$; then X, with the topology it inherits from $\mathbb{R}^D$, is a separable metrizable space. Note that, because D is dense, π is injective.

We need to know that π is an isomorphism between $(C(T), \Sigma)$ and $(X, \mathcal{B})$, where $\mathcal{B}$ is the Borel σ-algebra of X. **P** Since the Borel σ-algebra of $\mathbb{R}^D$ is just the σ-algebra generated by the functionals $g \mapsto g(t) : \mathbb{R}^D \to \mathbb{R}$ as t runs over D (4A3Dc/4A3E), $\mathcal{B}$ is the σ-algebra of subsets of X generated by the functionals $g \mapsto g(t) : X \to \mathbb{R}$ for $t \in D$. So π is surely $(\Sigma, \mathcal{B})$-measurable. On the other hand, if $t \in X$, there is a sequence $\langle t_n \rangle_{n \in \mathbb{N}}$ in D converging to t, so that $\pi^{-1}(g)(t) = \lim_{n \to \infty} g(t_n)$ for every $g \in X$, and $g \mapsto \pi^{-1}(g)(t) : X \to \mathbb{R}$ is $\mathcal{B}$-measurable. Accordingly π^{-1} is $(\mathcal{B}, \Sigma)$-measurable. **Q**

(b) Let $\langle U_n \rangle_{n \in \mathbb{N}}$ be a sequence running over a base for the topology of T, with no U_n empty. For each $n \in \mathbb{N}$, $g \in \mathbb{R}^D$ set

$$\omega_n(g) = \sup_{t,u \in U_n \cap D} \min(1, g(t) - g(u)),$$

so that $\omega_n : \mathbb{R}^D \to [0,1]$ is T-measurable, where T is the Borel (or Baire) algebra of $\mathbb{R}^D$. For $g \in \mathbb{R}^D$, $g \in X$ iff g has an extension to a continuous function on T, that is,

for every $t \in T$, $k \in \mathbb{N}$ there is an $n \in \mathbb{N}$ such that $t \in U_n$ and $\omega_n(g) \leq 2^{-k}$.

Turning this round, $\mathbb{R}^D \setminus X$ is the projection onto the first coordinate of the set

$$Q = \bigcup_{k\in\mathbb{N}} \bigcap_{n\in\mathbb{N}} \{(g,t)\text{: either } t \notin U_n \text{ or } \omega_n(g) > 2^{-k}\} \subseteq \mathbb{R}^D \times T.$$

But (because every U_n is an open set and every ω_n is Borel measurable) Q is a Borel set in the analytic space $\mathbb{R}^D \times T$. So Q is analytic (423Eb) and $\mathbb{R}^D \setminus X$ is analytic (423Bb). Since $\mathbb{R}^D$, being Polish (4A2Qc), is a Radon space (434Kb), X is a Radon space (434F).

(c) The image measure $\nu = \mu\pi^{-1}$ on X is a Borel probability measure. Because X is a Radon space, ν is tight, and its completion $\hat{\nu}$ is a Radon measure.

By 454Nb, $\pi^{-1} : X \to C(T)$ is almost continuous if we give $C(T)$ the topology $\mathfrak{T}_c$. So the image measure $\lambda = \hat{\nu}(\pi^{-1})^{-1}$ is a Radon measure for $\mathfrak{T}_c$ (418I). But of course λ is the completion of μ, just because π is a bijection and $\hat{\nu}$ is the completion of ν.

454P Corollary Let T be an analytic metrizable space.

(a) $C(T)$, with either the topology $\mathfrak{T}_p$ of uniform convergence on finite subsets of T or the topology $\mathfrak{T}_c$ of uniform convergence on compact subsets of T, is a measure-compact Radon space.

(b) Let μ be a Baire probability measure on $\mathbb{R}^T$ such that $\mu^* C(T) = 1$. Then μ is τ-additive, so has a unique extension $\tilde{\mu}$ which is a Radon measure on $\mathbb{R}^T$. $\tilde{\mu}C(T) = 1$, and the subspace measure on $C(T)$ induced by $\tilde{\mu}$ is a Radon measure if $C(T)$ is given the topology $\mathfrak{T}_c$.

proof (a) Let μ be a probability measure on $C(T)$ which is either a Baire measure or a Borel measure with respect to either $\mathfrak{T}_p$ or $\mathfrak{T}_c$. Let $\tilde{\mu}$ be the completion of $\mu\restriction\Sigma$, where Σ is the σ-algebra generated by the functionals $f \mapsto f(t)$; because all these are $\mathfrak{T}_p$-continuous, Σ is certainly included in the Baire σ-algebra for $\mathfrak{T}_p$, so that $\Sigma \subseteq \operatorname{dom}\mu$. 454O tells us that $\tilde{\mu}$ is a Radon measure for $\mathfrak{T}_c$. Because $\mathfrak{T}_p$ is a coarser Hausdorff topology, $\tilde{\mu}$ is also a Radon measure for $\mathfrak{T}_p$. Also $\tilde{\mu}$ must extend μ, because its domain includes that of μ and the completion of μ must extend $\tilde{\mu}$ (in fact, of course, this means that $\tilde{\mu}$ is actually the completion of μ). Now $\tilde{\mu}$ is τ-additive (for either topology), so μ also is; as μ is arbitrary, $C(T)$ is measure-compact (for either topology). On the other hand, if μ is a Borel measure (for either topology), it must be tight for that topology; so that $C(T)$ is a Radon space.

(b) Write μ_C for the subspace measure on $C(T)$. Recall that the domain Σ of μ is just the σ-algebra generated by the functionals $f \mapsto f(t) : \mathbb{R}^T \to \mathbb{R}$, as t runs over T (4A3Na), so that the domain Σ_C of μ_C is the σ-algebra of subsets of $C(T)$ generated by the functionals $f \mapsto f(t) : C(T) \to \mathbb{R}$. By 454O, the completion $\hat{\mu}_C$ of μ_C is a Radon measure on $C(T)$ if we give $C(T)$ the topology $\mathfrak{T}_c$ of uniform convergence on compact subsets of T.

The embedding $C(T) \subseteq \mathbb{R}^T$ is of course continuous for $\mathfrak{T}_c$ and the product topology on $\mathbb{R}^T$, so we have a Radon image measure $\tilde{\mu}$ on $\mathbb{R}^T$ defined by saying that $\tilde{\mu}E = \hat{\mu}_C(E \cap C(T))$ whenever $E \cap C(T)$ is measured by $\hat{\mu}_C$. If $E \in \Sigma$, then

$$\tilde{\mu}E = \hat{\mu}_C(E \cap C(T)) = \mu_C(E \cap C(T)) = \mu^*(E \cap C(T)) = \mu E$$

because $\mu^* C(T) = 1$, so $\tilde{\mu}$ extends μ. Of course $\tilde{\mu}C(T) = 1$ and the subspace measure on $C(T)$ induced by $\tilde{\mu}$ is just $\hat{\mu}_C$, so is a Radon measure with respect to $\mathfrak{T}_c$.

Finally, because μ has an extension to a Radon measure, it must itself be τ-additive. Because Σ includes a base for the topology of $\mathbb{R}^T$, μ can have only one extension to a Radon measure on $\mathbb{R}^T$ (415H(iv)).

454X Basic exercises >(a) Let μ be Lebesgue measure on $[0,1]$. Let $X_0 \subseteq [0,1]$ be a set of inner measure zero and outer measure 1. Set $X_1 = [0,1] \setminus X_0$; for each i, let μ_i be the subspace measure on X_i and Σ_i its domain. Show that we have a finitely additive functional λ defined on $\Sigma_0 \otimes \Sigma_1$ by the formula

$$\lambda((E \cap X_0) \times (F \cap X_1)) = \mu(E \cap F) \text{ for all } E,\ F \in \operatorname{dom}\mu,$$

and that λ has no extension to a measure on $X_0 \times X_1$.

(b) Adapt the example of 419K to provide a counter-example for 454G if we omit the hypothesis that the marginal measures $\mu_{\{i\}}$ must be perfect.

(c) Adapt the example of 419K/454Xb to provide a counter-example for 454H if we omit the hypothesis that the (X_n, Σ_n) must be standard Borel spaces. (*Hint*: if $z \in \prod_{i\leq n} X_i$, try $\nu_z(E) = 1$ if $z(n) \in E$, 0 otherwise.)

>(d) Let X be a set and Σ a σ-algebra of subsets of X. Let us say that (X, Σ) has the **perfect measure property** if every totally finite measure with domain Σ is perfect. Show that (i) if (X, Σ) has the perfect measure property, so does (E, Σ_E) for any $E \in \Sigma$, where Σ_E is the subspace σ-algebra on E (ii) if $\langle (X_i, \Sigma_i)\rangle_{i\in I}$ is a family of spaces with the perfect measure property, then $(\prod_{i\in I} X_i, \widehat{\bigotimes}_{i\in I}\Sigma_i)$ has the perfect measure property.

(e) Let X be a set and Σ a σ-algebra of subsets of X. Let us say that (X, Σ) has the **countably compact measure property** if every totally finite measure with domain Σ is countably compact. Show that (i) if (X, Σ) has the countably compact measure property it has the perfect measure property (ii) if (X, Σ) has the countably compact measure property so does (E, Σ_E) for every $E \in \Sigma$, where Σ_E is the subspace σ-algebra on E (iii) if $\langle (X_i, \Sigma_i)\rangle_{i\in I}$ is a family of spaces with the countably compact measure property, then $(\prod_{i\in I} X_i, \widehat{\bigotimes}_{i\in I}\Sigma_i)$ has the countably compact measure property.

(f) Suppose that (X, Σ) has the countably compact measure property. (i) Let μ be a totally finite measure with domain Σ, (Y, T, ν) a measure space, and $f : X \to Y$ an inverse-measure-preserving function. Show that μ has a disintegration $\langle \mu_y\rangle_{y\in Y}$ over ν which is consistent with f. (ii) Let Y be any set, T any σ-algebra of subsets of Y, and λ a probability measure with domain $\Sigma\widehat{\otimes}\mathrm{T}$. Show that there is a family $\langle \mu_y\rangle_{y\in Y}$ of probability measures on X such that $\lambda W = \int \mu_y W^{-1}[\{y\}]\nu(dy)$ for every $W \in \Sigma\widehat{\otimes}\mathrm{T}$, where ν is the marginal measure of λ on Y. (*Hint*: 452M.)

(g) (i) Let X be any set, and Σ the countable-cocountable algebra on X. Show that (X, Σ) has the countably compact measure property. (ii) Show that any standard Borel space has the countably compact measure property.

(h) Let (X, Σ) be a space with the perfect measure property, and T the smallest σ-algebra including Σ and closed under Souslin's operation. Show that (X, T) has the perfect measure property.

(i) Let X be a Radon Hausdorff space, and Σ the algebra of universally measurable sets in X (434D). Show that (X, Σ) has the countably compact measure property.

>(j) Let $\langle X_i\rangle_{i\in I}$ be a family of real-valued random variables. Show that $\langle X_i\rangle_{i\in I}$ is independent iff its distribution is the product of the distributions of the X_i, and is then a quasi-Radon measure on $\mathbb{R}^I$. (*Hint*: 272G, 415E.)

(k) Let I be a set and ν, ν' two quasi-Radon measures on $\mathbb{R}^I$ such that $\int e^{if(x)}\nu(dx) = \int e^{if(x)}\nu'(dx)$ for every continuous linear functional $f : \mathbb{R}^I \to \mathbb{R}$. Show that $\nu = \nu'$.

>(l) Let Σ be the σ-algebra of subsets of $C([0, \infty[)$ generated by the functionals $f \mapsto f(t)$ for $t \geq 0$. Give $C([0, \infty[)$ the topology $\mathfrak{T}_c$ of uniform convergence on compact sets. (i) Show that $\mathfrak{T}_c$ is Polish, and that $\Sigma \cap \mathfrak{T}_c$ is a base for $\mathfrak{T}_c$ which generates Σ as σ-algebra. (ii) Use this to give a quick proof of 454O in this case.

(m) Let T be a Polish space, and $\mathfrak{T}_c$ the topology on $C(T)$ of uniform convergence on compact sets. Show that if $\mathfrak{T}$ is any Hausdorff topology on $C(T)$, coarser than $\mathfrak{T}_c$, such that all the functionals $f \mapsto f(t)$, for $t \in T$, are Baire measurable for $\mathfrak{T}$, then $(C(T), \mathfrak{T})$ is a measure-compact Radon space.

454Y Further exercises (a) In 454A, show that μ is weakly α-favourable (definition: 451U) if every μ_i is.

(b) Let Σ be the algebra of Lebesgue measurable subsets of $\mathbb{R}$. Show that $(\mathbb{R}, \Sigma)$ has the perfect measure property (454Xd) iff $\mathfrak{c}$ is measure-free.

(c) Let Σ be the Borel σ-algebra of ω_1 with its order topology. Show that (ω_1, Σ) has the perfect measure property. (*Hint*: 439Yf.)

(d) Let (X, Σ, μ) be a semi-finite measure space with a topology such that μ is inner regular with respect to the closed sets, T a second-countable space and Y a separable metrizable space. Suppose that $\phi : X \times T \to Y$ is continuous in the second variable and measurable in the first, as in 454N. Show that μ is inner regular with respect to $\mathcal{K} = \{K : K \subseteq X, \phi{\restriction}K \times T \text{ is continuous}\}$.

454 Notes and comments 454A generalizes Theorem 451J, which gave the same result (with essentially the same proof) for product measures. One of the themes of this section is the idea that we can deduce properties of measures on product spaces from properties of their marginal measures, that is, the image measures on the factors. The essence of 'compactness', 'countable compactness' and 'perfectness' is that we can find enough points in the measure space to do what we want. (See, for instance, the characterization of compactness in 343B, or Pachl's characterization of countable compactness in 452Ye.) Since the canonical feature of a product space is that we put in every point the Axiom of Choice provides us with, it's perhaps not surprising that such properties can be inherited by measures on product spaces.

Theorems 454C and 454D can be regarded as further variations on the same theme. A finitely additive non-negative functional on an algebra of sets will have an extension to a measure if, and only if, it is sequentially smooth in the sense that the measures of a decreasing sequence of sets with empty intersection converge to zero (413K). If we have a decreasing sequence of sets, with measures bounded away from zero, but with empty intersection, one interpretation of the phenomenon is that some points which ought to have been present got left out of the sets. What 454D tells us is that perfectness (and countable additivity) of the marginal measures is enough to ensure that there are enough points in the product to stop this happening. In effect, 454C tells us that it will be enough if every marginal but one is perfect.

These results are of course associated with the projective limit constructions in 418M-418Q. In the theorems there we had Radon measures, so that they were actually compact rather than perfect; in return for the stronger hypothesis on the measures, we could handle projective limits corresponding to rather small subsets of the product spaces (see the formulae in 418O-418Q). Just as in §418, the patterns change when we have countable rather than uncountable families to deal with (418P-418Q, 454H).

In 454J-454M, I insist rather arbitrarily that 'the' joint distribution of a family $\langle X_i \rangle_{i \in I}$ of real-valued random variables is the completion of a Baire measure on $\mathbb{R}^I$. Of course all the ideas can also be expressed in terms of the Baire measure itself, but I have sought a formulation which is consistent with the rules set out in §271. When I is countable, we get a Radon measure (454J(iii)), as in the finite-dimensional case. There are other cases in which the distribution is a quasi-Radon measure (454Xj). As always, we can ask whether the distribution is τ-additive; in this case it will have a canonical extension to a quasi-Radon measure (415N). Important examples of this phenomenon are described in 455D and 456K. Because $\mathbb{R}^I$ has a linear topological space structure, we have a notion of 'characteristic function' for any probability measure on $\mathbb{R}^I$ measuring the zero sets, and the characteristic function of a Baire measure determines that measure (454M, 454Xk).

In 454O, $C(T)$, with $\mathfrak{T}_c$, has a countable network (4A2Oe), so the subspace measure μ_C induced by μ on $C(T)$ must be a τ-additive topological measure with respect to $\mathfrak{T}_c$ (414Xc) and has a unique extension to a quasi-Radon measure on $C(T)$ (415M). The hard bit is the next step, showing that $C(T)$, under $\mathfrak{T}_c$, is a Radon space; this is the real point of 454N-454O. For the most important case, in which $T = [0, \infty[$, we have a useful simplification, because $\mathfrak{T}_c$ is actually Polish (454Xl). Even in this case, however, we need to observe that the measure we are seeking is a little more complicated than a simple completion of a measure on $\mathbb{R}^T$. We must complete the *subspace* measure on $C(T)$, and $C(T)$ is far from being a measurable set. The measure $\tilde{\mu}$ of 454P will not as a rule be completion regular, for instance. Spaces of continuous functions are so important that it is worth noticing that the results here will be valid for various topologies on $C(T)$ (454Xm).

455 Markov processes and Brownian motion

For a 'Markov' process, in which the evolution of the system after a time t depends only on the state at time t, the general theory of §454 leads to a straightforward existence theorem (at least for random variables taking values in standard Borel spaces) dependent only on a natural consistency condition on the conditional distributions (455A). I apply this to the most important example, Brownian motion, in 455C.

455A Theorem Let T be a totally ordered set with least element a, and for each $t \in T$ let (X_t, Σ_t) be a standard Borel space. Set $X = \prod_{t\in T} X_t$ and for each $t \in T$ let $\pi_t : X \to X_t$ be the coordinate map. Let μ_a be a probability measure with domain Σ_a. Suppose that we are given, for each pair $s < t$ in T, a family $\langle \nu_x^{(s,t)}\rangle_{x\in X_s}$ of probability measures on X_t all with domain Σ_t, and suppose that

(i) whenever $s < t$ in T and $E \in \Sigma_t$, $x \mapsto \nu_x^{(s,t)}(E)$ is Σ_s-measurable,

(ii) whenever $s < t < u$ in T, $x \in X_s$ and $E \in \Sigma_u$, then

$$\nu_x^{(s,u)}(E) = \int \nu_y^{(t,u)}(E)\nu_x^{(s,t)}(dy).$$

Then there is a unique probability measure μ on X, with domain $\widehat{\bigotimes}_{t\in T}\Sigma_t$, such that μ_a is the image measure $\mu\pi_a^{-1}$ and, writing μ_t for the image measure on X_t, $\mu_t(E) = \int \nu_x^{(s,t)}(E)\mu_s(dx)$ for every $E \in \Sigma_t$ whenever $s < t$ in T. Moreover, if $J \subseteq T$ is a finite set containing a, and we write $\tilde\pi_J$ for the canonical map from X onto $Z_J = \prod_{t\in J} X_t$ and $\tilde\mu_J$ for the image measure $\mu\tilde\pi_J^{-1}$, then for any $\tilde\mu_J$-integrable real-valued function f we have

$$\int f d\tilde\mu_J = \iint \dots \iint f(x_0, \dots, x_n)\nu_{x_{n-1}}^{(t_{n-1},t_n)}(dx_n)$$
$$\nu_{x_{n-2}}^{(t_{n-2},t_{n-1})}(dx_{n-1}) \dots \nu_{x_0}^{(a,t_1)}(dx_1)\mu_a(dx_0)$$

where $t_0 = a, t_1, \dots, t_n$ are the elements of J written in ascending order.

proof (a) For each finite set $I \subseteq T$, write $\mathrm{T}_I = \widehat{\bigotimes}_{t\in I}\Sigma_t$. If $I = \{t_0, t_1, \dots, t_n\}$ is a finite subset of T with $a = t_0 < t_1 < \dots < t_n$, then we have a probability measure λ_I on Z_I with domain T_I such that

$$\int f d\lambda_I = \iint \dots \iint f(x_0, \dots, x_n)\nu_{x_{n-1}}^{(t_{n-1},t_n)}(dx_n)$$
$$\nu_{x_{n-2}}^{(t_{n-2},t_{n-1})}(dx_{n-1}) \dots \nu_{x_0}^{(a,t_1)}(dx_1)\mu_a(dx_0)$$

for every λ_I-integrable function f. **P** Use 454H on the finite sequence $(X_{t_0}, \dots, X_{t_n})$. The measures ν_z required by 454H must be constructed by the rule

$$\nu_z = \nu_{z(t_m)}^{(t_m,t_{m+1})}$$

for $m < n$, $z \in \prod_{i\le m} X_{t_i}$, while of course $\nu_\emptyset = \mu_a$. (Having a finite sequence rather than an infinite one clearly makes things easier; we can stop the argument at the end of part (b) of the proof of 454H.) **Q**

(b) Of course the point of this is that these measures λ_I form a consistent family; if $a \in I \subseteq J \in [T]^{<\omega}$, then the canonical projection $\pi_{IJ} : Z_J \to Z_I$ is inverse-measure-preserving. **P** It is enough to consider the case in which J has just one more point than I, since then we can induce on $\#(J \setminus I)$. In this case, express J as $\{t_0, \dots, t_n\}$ where $a = t_0 < \dots < t_n$, and suppose that $I = J \setminus \{t_m\}$. If $W \in \mathrm{T}_I$, then

$$\begin{aligned}\lambda_J\pi_{IJ}^{-1}[W] &= \int \dots \iint \dots \int \chi W(x_0, \dots, x_{m-1}, x_{m+1}, \dots, x_n)\nu_{x_{n-1}}^{(t_{n-1},t_n)}(dx_n)\\ &\qquad \dots \nu_{x_m}^{(t_m,t_{m+1})}(dx_{m+1})\nu_{x_{m-1}}^{(t_{m-1},t_m)}(dx_m) \dots \mu_a(dx_0)\\ &= \int \dots \iint g_{(x_0,\dots,x_{m-1})}(x_{m+1})\nu_{x_m}^{(t_m,t_{m+1})}(dx_{m+1}) \qquad (*)\\ &\qquad \nu_{x_{m-1}}^{(t_{m-1},t_m)}(dx_m) \dots \mu_a(dx_0)\end{aligned}$$

where

$$g_{(x_0,\dots,x_{m-1})}(x_{m+1}) = \int \dots \int \chi W(x_0,\dots,x_{m-1},x_{m+1},\dots,x_n) \\ \nu_{x_{n-1}}^{(t_{n-1},t_n)}(dx_n)\dots\nu_{x_{m+1}}^{(t_{m+1},t_{m+2})}(dx_{m+2}).$$

Here, of course, we use the hypothesis (ii); since

$$\nu_{x_{m-1}}^{(t_{m-1},t_{m+1})}(E) = \int \nu_{x_m}^{(t_m,t_{m+1})}(E)\nu_{x_{m-1}}^{(t_{m-1},t_m)}(dx_m)$$

for every $E \in \Sigma_{t_{m+1}}$, and since $g_{(x_0,\dots,x_{m-1})}$ is bounded and $\nu_{x_{m-1}}^{(t_{m-1},t_{m+1})}$-integrable,

$$\int g_{(x_0,\dots,x_{m-1})}(x_{m+1})\nu_{x_{m-1}}^{(t_{m-1},t_{m+1})}(dx_{m+1}) \\ = \iint g_{(x_0,\dots,x_{m-1})}(x_{m+1})\nu_{x_m}^{(t_m,t_{m+1})}(dx_{m+1})\nu_{x_{m-1}}^{(t_{m-1},t_m)}(dx_m)$$

(452F). Substituting this into (*) above,

$$\begin{aligned}\lambda_J\pi_{IJ}^{-1}[W] &= \int \dots \iint g_{(x_0,\dots,x_{m-1})}(x_{m+1}) \\ &\qquad \nu_{x_m}^{(t_m,t_{m+1})}(dx_{m+1})\nu_{x_{m-1}}^{(t_{m-1},t_m)}(dx_m)\dots\mu_a(dx_0) \\ &= \int \dots \int g_{(x_0,\dots,x_{m-1})}(x_{m+1})\nu_{x_{m-1}}^{(t_{m-1},t_{m+1})}(dx_{m+1})\dots\mu_a(dx_0) \\ &= \int \dots \int \dots \int \chi W(x_0,\dots,x_{m-1},x_{m+1},\dots,x_n) \\ &\qquad \nu_{x_{n-1}}^{(t_{n-1},t_n)}(dx_n)\dots\nu_{x_{m-1}}^{(t_{m-1},t_{m+1})}(dx_{m+1})\dots\mu_a(dx_0) \\ &= \lambda_I W,\end{aligned}$$

applying the formula in (a) again. **Q**

(Some of the formulae here are inappropriate if $m = n$. In this case, of course,

$$\begin{aligned}\lambda_J\pi_{IJ}^{-1}[W] &= \int \dots \int \chi W(x_0,\dots,x_{n-1})\nu_{x_{n-1}}^{(t_{n-1},t_n)}(dx_n)\dots\mu_a(dx_0) \\ &= \int \dots \int \chi W(x_0,\dots,x_{n-1})\nu_{x_{n-2}}^{(t_{n-2},t_{n-1})}(dx_{n-1})\dots\mu_a(dx_0) \\ &= \lambda_I W.)\end{aligned}$$

(c) We also see from the formulae in (a) that if $J \subseteq T$ is of the form $\{t_0,\dots,t_n\}$ with $n \geq 1$ and $a = t_0 < \dots < t_n$, then for any λ_J-integrable function f

$$\int f d\lambda_J = \iint \dots \iint f(x_0,\dots,x_n)\nu_{x_{n-1}}^{(t_{n-1},t_n)}(dx_n) \\ \nu_{x_{n-2}}^{(t_{n-2},t_{n-1}}(dx_{n-1})\dots\nu_{x_0}^{(a,t_1)}(dx_1)\mu_a(dx_0) \\ = \iint f(x_0,\dots,x_n)\nu_{x_{n-1}}^{(t_{n-1},t_n)}(dx_n)\lambda_I(d(x_0,\dots,x_{n-1}))$$

where $I = \{t_0,\dots,t_{n-1}\}$.

(d) Part (b) tells us that we have a consistent family of measures on the finite products Z_J, and therefore have a functional λ on $\bigotimes_{t\in T}\Sigma_t$ defined by setting $\lambda\tilde{\pi}_J^{-1}[W] = \lambda_J W$ for every finite $J \subseteq T$ containing a and $W \in \bigotimes_{t\in J}\Sigma_t$, writing $\tilde{\pi}_J : X \to Z_J$ for the canonical maps. λ is finitely additive, and its images $\mu_t = \lambda\pi_t^{-1}$ are all countably additive because they are also images of measures $\lambda_{\{a,t\}}$. So we have a measure μ extending λ, by 454F. We have to check that each λ_J is the image measure $\mu\tilde{\pi}_J^{-1}$; but this is true because

they agree on $\bigotimes_{t\in J}\Sigma_t$ (using the Monotone Class Theorem in the form 136C, as always). So the integral formula sought for $\tilde{\mu}_J$ is just that obtained in part (a) for λ_J.

(e) Accordingly, if $s<t$, we can calculate $\mu_t E$, for $E\in\Sigma_t$, as follows: setting $J=\{a,s,t\}$, $I=J\setminus\{t\}$, we have

$$\mu_t E=\mu\pi_t^{-1}[E]=\mu\tilde{\pi}_J^{-1}[F]$$

(where $F=\{z : z\in Z_J,\ z(t)\in E\}$)

$$=\lambda_J F=\int \nu^{(s,t)}_{z(s)}(E)\lambda_I(dz)$$

(by (c))

$$=\int \nu^{(s,t)}_{w(s)}(E)\mu(dw)=\int \nu^{(s,t)}_x(E)\mu_s(dx).$$

455B Remarks (a) I noted in 454I that in theorems of this type we do not really need to know that the factors (X_t,Σ_t) are standard Borel spaces; what counts is that they should have the 'perfect measure property' (454Xd). In the present context, we may be able to do even better, since all that matters is that the marginal measures μ_t should be perfect, and we have a direct description of them from the formula $\mu_t=\int\nu^{(a,t)}_x\mu_a(dx)$. So if, for instance, we can show from this presentation that all the μ_t are tight (that is, inner regular with respect to compact sets), then we need no further control on the algebras Σ_t.

(b) The formula

$$\mu_t(E)=\int\nu^{(s,t)}_x(E)\mu_s(dx)\text{ for every }E\in\Sigma_t\text{ whenever }s<t\text{ in }T$$

in 455A is the defining property of a **Markov process**. In something closer to probabilists' language, it comes out as

$$\Pr(X_t\in E)=\mathbb{E}\big(\nu^{(s,t)}_{X_s}(E)\big)\text{ where }\nu^{(s,t)}_x(E)=\Pr(X_t\in E|X_s=x).$$

The idea is that $\langle X_t\rangle_{t\in T}$ is a family of random variables, and that we start from the assurance that 'history is irrelevant'; if, at time s, we wish to make guesses about the behaviour of X_t, the state of the system at a future time t, then we expect that it will be useful to look at the current state X_s, but once we know the value of X_s then any further information about $X_{s'}$ for $s'<s$ will tell us nothing more about X_t. We are given the distributions $\nu^{(s,t)}_x$, which can be thought of as the conditional distributions of X_t given that $X_s=x$, or (in the language of §452) as a disintegration of the joint distribution of (X_s,X_t) over the distribution of X_s. The condition (ii) of 455A is plainly necessary if the system is going to make sense at all; the content of the theorem is that this condition is also sufficient (at least when the random variables X_t are taking values in standard spaces) to ensure that the system as a whole can indeed be represented as a family of random variables, in Kolmogorov's sense, on a suitable probability space.

455C Brownian motion As an example of the use of 455A I give a first existence proof for **Brownian motion** or **Wiener measure**.

Theorem There are a probability space (Ω,Σ,μ) and a family $\langle X_t\rangle_{t\geq 0}$ of real-valued random variables on Ω such that

(i) $X_0=0$ almost everywhere;

(ii) whenever $0\leq s<t$ then X_t-X_s is normally distributed with expectation 0 and variance $t-s$;

(iii) whenever $0\leq t_1<\ldots<t_n$, then $X_{t_2}-X_{t_1},X_{t_3}-X_{t_2},\ldots,X_{t_n}-X_{t_{n-1}}$ are independent.

proof (a) In 455A, take $T=[0,\infty[$, so that $a=0$; take $\mathbb{R}$ for each of the factor spaces, so that $X=\langle X_t\rangle_{t\geq 0}$ becomes a name for the identity function on the product $\Omega=\mathbb{R}^T$ (instead of the name of the product itself!), and each Σ_t is the Borel σ-algebra $\mathcal{B}$ of $\mathbb{R}$. Let μ_0 be the Borel probability measure on $\mathbb{R}$ which gives measure 1 to $\{0\}$, and whenever $0\leq s<t$, $x\in\mathbb{R}$ let $\nu^{(s,t)}_x$ be the distribution of a normal random variable with expectation x and variance $t-s$. (Strictly speaking, since elsewhere I insist that a distribution is a Radon measure, and that a Radon measure is complete, $\nu^{(s,t)}_x$ must be the restriction of such a distribution to $\mathcal{B}$.)

(b) The condition

whenever $0 \leq s < t$ and $E \in \mathcal{B}$, $x \mapsto \nu_x^{(s,t)}(E)$ is $\mathcal{B}$-measurable,

in 455A is elementary;

$$\nu_x^{(s,t)}(E) = \frac{1}{\sqrt{2\pi(t-s)}} \int_E e^{-(y-x)^2/2(t-s)} dy$$

(274Ad) is actually a continuous function of x, because the integrand is continuous as a function of two variables (and is dominated by an integrable function as x varies over any bounded interval). As for the condition

whenever $0 \leq s < t < u$, $x \in \mathbb{R}$ and $E \in \mathcal{B}$, then $\nu_x^{(s,u)}(E) = \int \nu_y^{(t,u)}(E)\nu_x^{(s,t)}(dy)$,

this is really just the theorem that the sum of independent normal random variables is normal (274B). For if U, V are independent normal random variables, U has expectation x and variance $t-s$, and V has expectation 0 and variance $u-t$, then $U+V$ will be normal with expectation x and variance $u-s$, so that $\nu_x^{(s,u)}(E) = \Pr(U+V \in E)$. On the other side of the equation, $\nu_x^{(s,t)}$ is the distribution of U, while $\nu_y^{(t,u)}$ is the distribution of $V+y$; so that

$$\begin{aligned}
\nu_x^{(s,u)}(E) &= \Pr(U+V \in E) = (\nu_x^{(s,t)} * \nu_0^{(t,u)})(E) \\
&\text{(272S)} \\
&= \int \nu_0^{(t,u)}(E-y)\nu_x^{(s,t)}(dy) \\
&\text{(257Xb with 257D, or 444A)} \\
&= \int \nu_y^{(t,u)}(E)\nu_x^{(s,t)}(dy),
\end{aligned}$$

as required.

(c) Thus the conditions of 455A are satisfied, and we get a probability measure μ on $\Omega = \mathbb{R}^{[0,\infty[}$. The conclusion

μ_a is the image measure $\mu\pi_a^{-1}$

says just that $\Pr(X_0 = 0) = 1$. If $s < t$ and $E \in \mathcal{B}$, then

$$\begin{aligned}
\Pr(X_t - X_s \in E) &= \iiint \chi E(z-y)\nu_y^{(s,t)}(dz)\nu_x^{(0,s)}(dy)\mu_0(dx) \\
&= \int \nu_y^{(s,t)}(E+y)\nu_0^{(0,s)}(dy) \\
&= \int \nu_0^{(s,t)}(E)\nu_0^{(0,s)}(dy) = \nu_0^{(s,t)}(E),
\end{aligned}$$

so $X_t - X_s$ has distribution $\nu_0^{(s,t)}$, that is, is normally distributed with expectation 0 and variance $t-s$. Similarly, if $0 \leq t_1 < \ldots < t_n$ and $E_1, \ldots, E_{n-1} \in \mathcal{B}$, then

$$\begin{aligned}\Pr(X_{t_{i+1}} - X_{t_i} \in E_i \text{ for } 1 \le i < n)&\\
&= \iint \dots \int \chi E_1(x_2 - x_1)\chi E_2(x_3 - x_2) \dots \chi E_{n-1}(x_n - x_{n-1})\\
&\qquad \nu_{x_{n-1}}^{(t_{n-1},t_n)}(dx_n) \dots \nu_{x_0}^{(0,t_1)}(dx_1)\mu_0(dx_0)\\
&= \iint \dots \int \chi(E_1 + x_1)(x_2)\chi(E_2 + x_2)(x_3) \dots \chi(E_{n-1} + x_{n-1})(x_n)\\
&\qquad \nu_{x_{n-1}}^{(t_{n-1},t_n)}(dx_n) \dots \nu_{x_0}^{(0,t_1)}(dx_1)\mu_0(dx_0)\\
&= \iiint \dots \iint \chi(E_{n-1} + x_{n-1})(x_n)\nu_{x_{n-1}}^{(t_{n-1},t_n)}(dx_n)\\
&\qquad \chi(E_{n-2} + x_{n-2})(x_{n-1})\nu_{x_{n-2}}^{(t_{n-2},t_{n-1})}(dx_{n-1})\\
&\qquad \dots \chi(E_1 + x_1)(x_2)\nu_{x_1}^{(t_1,t_2)}(dx_2)\nu_{x_0}^{(0,t_1)}(dx_1)\mu_0(dx_0)\\
&= \nu_0^{(t_{n-1},t_n)}(E_{n-1})\nu_0^{(t_{n-2},t_{n-1})}(E_{n-2}) \dots \nu_0^{(t_1,t_2)}(E_1)\\
&= \prod_{i=1}^{n-1} \Pr(X_{i+1} - X_i \in E_i).\end{aligned}$$

So $X_{t_2} - X_{t_1}, \dots, X_{t_n} - X_{t_{n-1}}$ are independent.

455D This construction of Brownian motion is sufficient to show that there is a process, satisfying the defining conditions (i)-(iii), which can be studied with the tools of measure theory. It gives no hint of the most important property of Brownian motion, that 'sample paths are continuous'. With some simple inequalities from Chapter 27 and the ideas of 454N-454P, we can find a proof of this, as follows.

Theorem In 455C, we can take Ω to be $C([0,\infty[)$ and μ to be a Radon measure when $C([0,\infty[)$ is given the topology $\mathfrak{T}_c$ of uniform convergence on compact sets, while $X_t(f) = f(t)$ for $f \in C([0,\infty[)$.

proof (a) The construction in 455C in fact gives us $\Omega = \mathbb{R}^{[0,\infty[}$, $X_t(f) = f(t)$ for $f \in \mathbb{R}^{[0,\infty[}$, and a Baire measure μ. The main part of the argument here (down to the end of (e)) is devoted to showing that $\mu^*C([0,\infty[) = 1$; the result will then follow easily from 454Pb.

(b) ❓ Suppose, if possible, that $\mu^*C([0,\infty[) < 1$. Then there is a non-negligible Baire set $H \subseteq \mathbb{R}^{[0,\infty[} \setminus C([0,\infty[)$. There is a countable set $D \subseteq [0,\infty[$ such that H is determined by coordinates in D (4A3Nb); we may suppose that D includes $\mathbb{Q} \cap [0,\infty[$.

(c) (The key.) Let q, q' be rational numbers such that $0 \le q < q'$, and $\epsilon > 0$. Then

$$\Pr(\sup_{t \in D \cap [q,q']} |X_t - X_q| \ge \epsilon) \le \frac{18\sqrt{q'-q}}{\epsilon\sqrt{2\pi}} e^{-\epsilon^2/18(q'-q)}.$$

P If $q = t_0 < t_1 < \dots < t_n = q'$, set $Y_i = X_{t_i} - X_{t_{i-1}}$ for $1 \le i \le n$, so that $X_{t_m} - X_q = \sum_{i=1}^m Y_i$ for $1 \le m \le n$, and $Y_1, \dots, Y_n$ are independent. By Etemadi's lemma (272U),

$$\begin{aligned}\Pr(\sup_{i \le n} |X_{t_i} - X_q| \ge \epsilon) &\le 3 \max_{i \le n} \Pr(|X_{t_i} - X_q| \ge \tfrac{1}{3}\epsilon)\\
&= 3 \max_{1 \le i \le n} \Pr(\tfrac{1}{\sqrt{t_i - q}}|X_{t_i} - X_q| \ge \tfrac{\epsilon}{3\sqrt{t_i - q}})\\
&= 6 \max_{1 \le i \le n} \frac{1}{\sqrt{2\pi}} \int_{\epsilon/3\sqrt{t_i-q}}^\infty e^{-x^2/2} dx\end{aligned}$$

(because $\frac{1}{\sqrt{t_i - q}} X_{t_i} - X_q$ is standard normal)

$$\begin{aligned}&= \frac{6}{\sqrt{2\pi}} \int_{\epsilon/3\sqrt{q'-q}}^\infty e^{-x^2/2} dx\\
&\le \frac{18\sqrt{q'-q}}{\epsilon\sqrt{2\pi}} e^{-\epsilon^2/18(q'-q)}\end{aligned}$$

by 274Ma. Thus if $I \subseteq [q, q']$ is any finite set containing q and q',

$$\Pr(\sup_{t\in I} |X_t - X_q| \geq \epsilon) \leq \frac{18\sqrt{q'-q}}{\epsilon\sqrt{2\pi}} e^{-\epsilon^2/18(q'-q)}.$$

Taking $\langle I_n\rangle_{n\in\mathbb{N}}$ to be a non-decreasing sequence of finite sets with union $D\cap[q,q']$, starting from $I_0 = \{q, q'\}$, we get

$$\begin{aligned}\Pr(\sup_{t\in D\cap[q,q']} |X_t - X_q| \geq \epsilon) &= \lim_{n\to\infty} \Pr(\sup_{t\in I_n} |X_t - X_q| \geq \epsilon)\\ &\leq \frac{18\sqrt{q'-q}}{\epsilon\sqrt{2\pi}} e^{-\epsilon^2/18(q'-q)},\end{aligned}$$

as required. **Q**

(d) If $\epsilon > 0$ and $n \geq 1$, then

$$\begin{aligned}&\Pr(\text{there are } t,\, u \in D\cap[0,n] \text{ such that } |t-u| \leq \frac{1}{n^2} \text{ and } |X_t - X_u| \geq 3\epsilon)\\ &\qquad \leq \frac{18n^2}{\epsilon\sqrt{2\pi}} e^{-n^2\epsilon^2/18}.\end{aligned}$$

P Divide $[0,n]$ into n^3 intervals $[q_i, q_{i+1}]$ of length $1/n^2$. For each of these,

$$\Pr(\sup_{t\in D\cap[q_i,q_{i+1}]} |X_t - X_{q_i}| \geq \epsilon) \leq \frac{18}{n\epsilon\sqrt{2\pi}} e^{-n^2\epsilon^2/18}.$$

So

$$\Pr(\text{there are } i < n^3,\, t \in D\cap[q_i,q_{i+1}] \text{ such that } |X_t - X_{q_i}| \geq \epsilon)$$

is at most $\frac{18n^2}{\epsilon\sqrt{2\pi}} e^{-n^2\epsilon^2/18}$.

But if $t,\, u \in [0,n]$ and $|t-u| \leq 1/n^2$ and $|X_t - X_u| \geq 3\epsilon$, there must be an $i < n^3$ such that both t and u belong to $[q_i, q_{i+2}]$, so that either there is a $t' \in D\cap[q_i,q_{i+1}]$ such that $|X_{t'} - X_{q_i}| \geq \epsilon$ or there is a $t' \in D\cap[q_{i+1},q_{i+2}]$ such that $|X_{t'} - X_{q_{i+1}}| \geq \epsilon$. So

$$\begin{aligned}&\Pr(\text{there are } t,\, u \in D\cap[0,n] \text{ such that } |t-u| \leq \frac{1}{n^2} \text{ and } |X_t - X_u| \geq 3\epsilon)\\ &\quad \leq \Pr(\text{there are } i < n^3,\, t \in D\cap[q_i,q_{i+1}] \text{ such that } \text{ and } |X_t - X_{q_i}| \geq \epsilon)\\ &\quad \leq \frac{18n^2}{\epsilon\sqrt{2\pi}} e^{-n^2\epsilon^2/18},\end{aligned}$$

as required. **Q**

(e) So if we take $G_{\epsilon n}$ to be the Baire set

$$\begin{aligned}\{f : f \in \mathbb{R}^{[0,\infty[},\ &\text{there are } t,\, u \in D\cap[0,n] \text{ such that } |t-u| \leq \frac{1}{n^2}\\ &\text{and } |f(t) - f(u)| \geq 3\epsilon\},\end{aligned}$$

we have

$$\mu G_{\epsilon n} \leq \frac{18n^2}{\epsilon\sqrt{2\pi}} e^{-n^2\epsilon^2/18},$$

and $\lim_{n\to\infty} \mu G_{\epsilon n} = 0$. We can therefore find a strictly increasing sequence $\langle n_k\rangle_{k\in\mathbb{N}}$ in $\mathbb{N}$ such that $\sum_{k=1}^{\infty} \mu(G_{1/k,n_k}) < \mu H$, so that there is an $f \in H \setminus \bigcup_{k\geq 1} G_{1/k,n_k}$.

What this means is that if $k \geq 1$ and $t,\, u \in D\cap[0,n_k]$ are such that $|t-u| \leq \frac{1}{n_k^2}$, then $|f(t) - f(u)| < \frac{3}{k}$. Since $n_k \to \infty$ as $k \to \infty$, there is a continuous function f' such that $f'\restriction D = f\restriction D$. But H is determined by coordinates in D, so f' belongs to $H \cap C([0,\infty[)$, which is supposed to be empty. **X**

(f) Thus $\mu^* C([0,\infty[) = 1$. By 454Pb, we have an extension of μ to a measure $\tilde{\mu}$ such that $\tilde{\mu}C([0,\infty[) = 1$ and the subspace measure $\tilde{\mu}_C$ is a Radon measure for $\mathfrak{T}_c$. If we interpret the random variables $X_t(f) = f(t)$

as functions defined on the probability space $(\mathbb{R}^{[0,\infty[}, \tilde{\mu})$, they still have the properties (i)-(iii) of 455C, because $\tilde{\mu}$ extends μ; and since $C([0,1[)$ is $\tilde{\mu}$-conegligible, their restrictions to $C([0,\infty[)$, regarded as random variables on the probability space $(C([0,\infty[), \tilde{\mu}_C)$ will also have these properties, as required.

455X Basic exercises (a) In 455A, set $T = [0,\infty[$, let each (X_t, Σ_t) be $\mathbb{R}$ with its Borel σ-algebra, let μ_0 be any atomless Borel probability measure on $\mathbb{R}$, and for $x \in \mathbb{R}$, $0 \leq s < t$ let $\nu_x^{(s,t)}$ be the Borel measure on $\mathbb{R}$ giving measure 1 to $\{\psi(x, t-s)\}$, where

$$\begin{aligned}\psi(x,t) &= \tfrac{x}{1-xt} \text{ if } xt \neq 1 \text{ and } x \neq 0,\\ &= 0 \text{ if } xt = 1,\\ &= -\tfrac{1}{t} \text{ if } x = 0.\end{aligned}$$

Show that the conditions of 455A are satisfied, that the measure μ constructed in 455A is a Baire measure on $\mathbb{R}^T$, and that μ is not τ-additive. (*Hint*: setting $\phi(x)(t) = \psi(x,t)$, show that $\phi : \mathbb{R} \to \mathbb{R}^T$ is inverse-measure-preserving for μ_0 and μ, and that every point in $\mathbb{R}^T$ has a neighbourhood of zero measure.)

(b) Suppose, in 455A, that every (X_t, Σ_t) is $\mathbb{R}$ with its Borel σ-algebra, and that $\int y\nu_x^{(s,t)}(dy) = x$ whenever $s < t$ in T and $x \in \mathbb{R}$. Suppose also that $\int y\mu_0(dy) = \alpha$. Show that $\int \pi_t d\mu = \alpha$ for every $t \in T$ (that is, that all the random variables $\pi_t : X \to \mathbb{R}$ have the same expectation).

(c) Suppose, in 455C, we set $\nu_x^{(s,t)}(E) = \lambda_{t-s}(E-x)$, where λ_t is a Poisson distribution with expectation t, that is, $\lambda_t(E) = e^{-t}\sum_{m\in E\cap\mathbb{N}} t^m/m!$ (cf. 285Q, 285Xo). Show that we can again use 455A to build a measure on $\Omega = \mathbb{R}^{[0,\infty[}$, and that as in 455C the increments $X_t - X_s$ over non-overlapping intervals are independent.

(d) Show that, in 455A, we can set $\nu_x^{(s,t)}(E) = \lambda_{t-s}(E-x)$, where λ_t is a Cauchy distribution with centre 0 and scale parameter t (285Xm). Show that we obtain a measure on $\Omega = \mathbb{R}^{[0,\infty[}$, such that, as in 455C, the increments $X_t - X_s$ over non-overlapping intervals are independent.

(e) (i) The **standard gamma distribution** with parameter γ is the probability distribution λ_γ on $\mathbb{R}$ with probability density function $t \mapsto \frac{1}{\Gamma(\gamma)}t^{\gamma-1}e^{-t}$ for $t > 0$. Show that its expectation is γ. (*Hint*: 225Xj(iv).) Show that its variance is γ. (ii) Show that if X and Y are independent random variables with standard gamma distributions, then $X + Y$ has a standard gamma distribution. (*Hint*: 272T, 252Yk.) (iii) Show that $\lim_{\gamma\downarrow 0}\gamma\Gamma(\gamma) = 1$, so that $\frac{1}{\gamma}\lim_{\gamma\downarrow 0}\lambda_\gamma[1,\infty[= \int_1^\infty \frac{1}{t}e^{-t} > 0$. (iv) Show that, in 455A, we can set $\nu_x^{(s,t)}(E) = \lambda_{t-s}(E-x)$ to get a process in which increments over non-overlapping intervals are independent, the set of non-decreasing functions has full outer measure, and the set of continuous functions is negligible. (v) Show that this process can be represented by a Radon measure on $\mathbb{R}^{[0,\infty[}$. (*Hint*: 438P, 432D.)

(f) Use 272Ye to simplify the formulae in the proof of 455D.

455Y Further exercises (a) Suppose, in 455A, that $T = \mathbb{N}$ or $T = [0,\infty[$, that every (X_t, Σ_t) is $\mathbb{R}$ with its Borel σ-algebra, and that $\nu_x^{(s,t)}(E) = \nu_0^{(0,t-s)}(E-x)$ whenever $x \in \mathbb{R}$, $E \in \mathcal{B}$ and $s < t$. Take $t \in T$ and let $\tilde{\mu}_{[0,t]}$ be the image of μ on $\prod_{0\leq s\leq t} X_s$. Show that we have a disintegration of μ over $\tilde{\mu}_{[0,t]}$ defined by the formula

$$\mu W = \int \mu\{f : g^\frown f \in W\}\tilde{\mu}_{[0,t]}(dg),$$

where for $g \in \prod_{0\leq s\leq t} X_s$, $f \in \prod_{s\in T} X_s$ we write $(g^\frown f)(s) = g(s)$ if $s \leq t$, $g(t) + f(s-t)$ if $s \geq t$.

(b) Let $\langle X_n\rangle_{n\in\mathbb{Z}}$ be a double-ended sequence of real-valued random variables such that (i) for each $n \in \mathbb{Z}$, $Y_n = X_{n+1} - X_n$ is independent of $\{X_i : i \leq n\}$ (ii) $\langle Y_n\rangle_{n\in\mathbb{Z}}$ is identically distributed. Show that the Y_n are essentially constant. (*Hint*: 285Yc.)

(c) Write D_n for $\{2^{-n}i : i \in \mathbb{N}\}$ and $D = \bigcup_{n\in\mathbb{N}} D_n$, the set of dyadic rationals in $[0,\infty[$. For $d \in D$ define $f_d \in C([0,\infty[)$ as follows. If $n \in \mathbb{N}$, $f_n(t) = 0$ if $t \leq n$, $t-n$ if $n \leq t \leq n+1$, 1 if $t \geq n+1$. If $d = 2^{-n}k$ where $n \geq 1$ and $k \in \mathbb{N}$ is odd, $f_d(t) = \max(0, \frac{1}{\sqrt{2^{n+1}}}(1 - 2^n|t-d|))$ for $t \geq 0$. Now let $\langle Z_d\rangle_{d\in D}$ be an independent family of standard normal distributions, and set $G_n(t) = \sum_{d\in D_n} f_d(t)Z_d$ for $t \geq 0$, so that each G_n is a random continuous function on $[0,\infty[$. Show that for any $n \in \mathbb{N}$, $\epsilon > 0$,

$$\Pr(\sup_{t\in[0,n]} |G_{n+1}(t) - G_n(t)| \geq \epsilon) \leq 2^n n \cdot \frac{2}{\sqrt{2\pi}} \int_{2\epsilon\sqrt{2^n}}^{\infty} e^{-x^2/2} dx,$$

and hence that $\langle G_n\rangle_{n\in\mathbb{N}}$ converges almost surely to a continuous function. Explain how to interpret this as a construction of the measure on $C([0,\infty[)$ described in 455D.

(d) Let $\langle\lambda_t\rangle_{t\in]0,\infty[}$ be any family of probability distributions on $\mathbb{R}$ such that $\lambda_s * \lambda_t = \lambda_{s+t}$ for all s, $t > 0$. Show that we can set $\nu_x^{(s,t)}(E) = \lambda_{t-s}(E - x)$ in 455A to obtain a measure on $\mathbb{R}^{[0,\infty[}$ such that the increments over non-overlapping intervals are independent.

(e) In 455Xc, show that the measure μ obtained on $\mathbb{R}^{[0,\infty[}$ is a Baire measure, and has an extension to a Radon measure $\tilde{\mu}$ on $\mathbb{R}^{[0,\infty[}$ such that $\tilde{\mu}Q = 1$, where Q is the set of non-decreasing functions $f : [0,\infty[\to \mathbb{N}$ such that $\lim_{t\downarrow 0} f(t) = 0$, $\lim_{s\downarrow t} f(s) - \lim_{s\uparrow t} f(s) \leq 1$ for every $t \geq 0$, and $\lim_{t\to\infty} f(t) = \infty$. (*Hint*: show that Q is a K-analytic space with metrizable compact sets, so is a Radon space.)

(f) In 455Xd, show that the measure μ obtained on $\mathbb{R}^{[0,\infty[}$ is a Baire measure, and that $C([0,\infty[)$ is negligible. (*Hint*: estimate $\Pr(|X_{(i+1)/n} - X_{i/n}| \leq \epsilon$ for every $i < n)$.)

(g) Let μ be the Radon measure on $C([0,\infty[)$ representing Brownian motion, and $\gamma > \frac{1}{2}$. Show that $\lim_{t\to\infty} t^{-\gamma} f(t) = 0$ for μ-almost every $f \in C([0,\infty[)$.

455 Notes and comments Obviously the principal applications of 455A will be with the totally ordered sets $\mathbb{N}$ and $[0,\infty[$, as in 454H and 455C. I use the letters t, T to suggest the probabilistic intuitions behind these results; we think of the spaces X_t in 455A as being the sets of possible states of a system at 'time' t, so that the measures $\nu_x^{(s,t)}$ are descriptions of how we believe the system is likely to evolve between times s and t, given that it is in state x at time s. In the case of 'discrete time', when we observe the system only at clearly separated moments, it is easy to handle non-Markov processes, in which evolution between times $n-1$ and n can depend on the whole history up to time $n-1$; thus in 454H the measures $\nu_z = \nu_z^{(n-1,n)}$ are defined for every $z \in \prod_{i<n} X_i$, but we make no attempt to describe measures $\nu_z^{(n-1,m)}$ for any $m > n$. In 'continuous time' we do need to say something about arbitrary time steps, and it is hard to formulate a consistency condition to fill the place of (ii) in 455A without limiting the kind of process being examined. At the cost of an appalling increase in complexity, of course, the formulae of 455A can be adapted to general processes, if we replace the 'current' state space X_t by the 'historical' state space $\prod_{a\leq s\leq t} X_s$. (For this product will still have the 'perfect measure property' of 454Xd.) We should finish up with a measure on $\prod_{t\in T}(\prod_{a\leq s\leq t} X_s)$. But the important applications, even when not Markov, are open to more economical and more enlightening approaches.

We really do need a least element a of T; see 455Yb. I find that in the exposition here I have made a rather wrenching change in notation between the abstract measure theory of 455A and the probability theory of 455C. I hope that despite the conflicting use of the symbol X this will give no trouble.

I remarked in the introduction to Chapter 27 that probability spaces themselves are rather shadowy objects in probability theory. The manoeuvres of 455C-455D are a typical example of the shifts we find ourselves making. Brownian motion is essentially defined by the properties (i)-(iii) in 455C; these determine the joint distribution of the family $\langle X_t\rangle_{t\in J}$ for any finite set $J \subseteq [0,\infty[$. We have a great deal of choice about the measure space Ω we choose to realize the process on. In 455C we have a Baire measure on $\mathbb{R}^{[0,\infty[}$, and in 455D we have a Radon measure on $C([0,\infty[)$. In both cases the measure is uniquely defined. The second is the more useful representation; for instance, it makes every sample path continuous, while in the first formulation the continuous paths are only a set of full outer measure; more important, we have a Radon measure on a Polish space, which gives us a springboard for further investigation.

Perhaps it is worth recalling here that a Baire measure on a completely regular space has at most one quasi-Radon measure extending it (415G). The step from 455C to 455D amounts to showing that Brownian motion, interpreted as a Baire probability measure on $\mathbb{R}^{[0,\infty[}$, has an extension to a Radon measure $\tilde{\mu}$ on $\mathbb{R}^{[0,\infty[}$ for which $C([0,\infty[)$ is conegligible, so that we have the option of regarding $\tilde{\mu}$ as a Radon measure on $C([0\infty[)$; by 454P or 454Xl, we can give $C([0,\infty[)$ either the topology of pointwise convergence or the topology of uniform convergence on compact sets. The point I wish to make is that the step from μ to $\tilde{\mu}$ is a canonical one and worth performing as soon as we know that μ is τ-additive, whether or not we come to a measure living on the continuous functions. In 455Xe, for instance, $\tilde{\mu}$ gives measure 1 to the set of non-decreasing functions, and this is clearly an essential property of the process.

There are of course many routes to the fundamental theorems 455C-455D, and I do not claim that the one described here is the 'best'. I use it because it is an instructive example of the class of problems which led to the theorems of this section. The excursion through a measure on $\mathbb{R}^{[0,\infty[}$ is by no means necessary; in 455Yc I sketch an alternative method ('Lévy's construction') which avoids it.

Generally it is true that interesting stochastic processes have much stronger properties than those described in 455A. Any construction using these abstract methods should be regarded as provisional; it may be a useful, even necessary, first confirmation that there is something there to work on, but we are likely to need much more penetrating techniques to form a proper conception of what we have found. The general argument above does however provide a clear description of what is necessary for the 'independent increments' property of Brownian motion: the fact that if $t_1 < t_2 < \ldots < t_n$ then $X_{t_2} - X_{t_1}, \ldots, X_{t_n} - X_{t_{n-1}}$ are independent. We need the Markov property (so that, given $X_{t_{n-1}}$, X_{t_n} is independent of previous history) and the translation property of the $\nu_x^{(s,t)}$, encapsulated in the formula $\nu_x^{(s,t)}(E) = \nu_0^{(s,t)}(E-x)$, which assures us that the distribution of $X_t - X_s$ is $\nu_0^{(s,t)}$ (so that $X_s, X_t - X_s$ are independent). It also has a place for 'temporal homogeneity', that is, the fact that $\nu_x^{(s,t)} = \nu_x^{(s',t')}$ whenever $t' - s' = t - s$ (455Ya). And the method does at least make it clear which property of normal distributions we need (part (b) of the proof of 455C), so leads us to examine other important processes (455Xc-455Xe, 455Yd). These are all based on families of 'infinitely divisible' distributions; for the general theory of such distributions, see Loève 77 or Fristedt & Gray 97.

456 Gaussian distributions

Uncountable powers of $\mathbb{R}$ are not as a rule measure-compact (439P, 455Xa). Accordingly distributions, in the sense of 454K, need not be τ-additive. But, as we have seen in 455D, some, at least, of the distributions most important to us are indeed τ-additive, and therefore have interesting canonical extensions. This section is devoted to a remarkable result, taken from Talagrand 81, concerning a class of distributions which are of great importance in probability theory. It demands a combination of techniques from classical probability theory and from the topological measure theory of this volume. I begin with the definition and fundamental properties of what I call 'centered Gaussian distributions' (456A-456E). These are minor adaptations of the classical finite-dimensional theory. Another relatively easy idea is that of 'universal' Gaussian distribution (456F-456H). In 456I we come to a much deeper result, a step towards classifying the ways in which a Gaussian family of n-dimensional random variables can accumulate at 0. The ideas are combined in 456J-456K to complete the proof of Talagrand's theorem that Gaussian distributions on powers of $\mathbb{R}$ are τ-additive.

456A Definitions (a) Write μ_G for the Radon probability measure on $\mathbb{R}$ which is the distribution of a standard normal random variable, that is, the probability distribution with density function $x \mapsto \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$ (274A). For any set I, write $\mu_G^{(I)}$ for the measure on $\mathbb{R}^I$ which is the product of copies of μ_G; this is always quasi-Radon (415E/453J); if I is countable, it is Radon (417Q); if $I = n \in \mathbb{N} \setminus \{0\}$, it is the probability distribution with density function $x \mapsto (2\pi)^{-n/2} e^{-x \cdot x/2}$ (272I); if $I = \emptyset$, it is the unique probability measure on the singleton set $\mathbb{R}^\emptyset$.

(b) I will use the phrase **centered Gaussian distribution** to mean a measure μ on a power $\mathbb{R}^I$ of $\mathbb{R}$ such that μ is the completion of a Baire measure (that is, is a distribution in the sense of 454K) and every

continuous linear functional $f : \mathbb{R}^I \to \mathbb{R}$ is either zero almost everywhere or is a normal random variable with zero expectation. (Note that I call the distribution concentrated on the point 0 in $\mathbb{R}^I$ a 'Gaussian distribution'.)

(c) If I is a set and μ is a centered Gaussian distribution on $\mathbb{R}^I$, its **covariance matrix** is the family $\langle \sigma_{ij} \rangle_{i,j \in I}$ where $\sigma_{ij} = \int x(i)x(j)\mu(dx)$ for $i, j \in I$. (The integral is always defined and finite because each function $x \mapsto x(i)$ is either essentially constant or normally distributed, and in either case is square-integrable.)

456B I start with some fundamental facts about Gaussian distributions.

Proposition (a) Suppose that I and J are sets, μ is a centered Gaussian distribution on $\mathbb{R}^I$, and $T : \mathbb{R}^I \to \mathbb{R}^J$ is a continuous linear operator. Then there is a unique centered Gaussian distribution on $\mathbb{R}^J$ for which T is inverse-measure-preserving; if J is countable, this is the image measure μT^{-1}.

(b) Let I be a set, and μ, ν two centered Gaussian distributions on $\mathbb{R}^I$. If they have the same covariance matrices they are equal.

(c) For any set I, $\mu_G^{(I)}$ is the centered Gaussian distribution on $\mathbb{R}^I$ with the identity matrix for its covariance matrix.

(d) Suppose that I is a countable set. Then a measure μ on $\mathbb{R}^I$ is a centered Gaussian distribution iff it is of the form $\mu_G^{(\mathbb{N})} T^{-1}$ where $T : \mathbb{R}^{\mathbb{N}} \to \mathbb{R}^I$ is a continuous linear operator.

(e) Suppose $\langle I_j \rangle_{j \in J}$ is a disjoint family of sets with union I, and that for each $j \in J$ we have a centered Gaussian distribution ν_j on $\mathbb{R}^{I_j}$. Then the product ν of the measures ν_j, regarded as a measure on $\mathbb{R}^I$, is a centered Gaussian distribution.

(f) Let I be any set, μ a centered Gaussian distribution on $\mathbb{R}^I$ and $E \subseteq \mathbb{R}^I$ a set such that μ measures E. Writing $-E = \{-x : x \in E\}$, $\mu(-E) = \mu E$.

proof (a)(i) For Baire sets $F \subseteq \mathbb{R}^J$, set $\nu F = \mu T^{-1}[F]$; this is always defined because T is continuous (4A3Kc). This makes ν a Baire probability measure on $\mathbb{R}^J$ for which T is inverse-measure-preserving. Because μ is complete, T is still inverse-measure-preserving for the completion $\hat{\nu}$ of ν (235Hc). If $g : \mathbb{R}^J \to \mathbb{R}$ is a continuous linear functional, so is $gT : \mathbb{R}^I \to \mathbb{R}$; now $\nu\{y : g(y) \leq \alpha\} = \mu\{x : gT(x) \leq \alpha\}$ for every α, so g and gT have the same distribution, and are both either zero a.e. or normal random variables. As g is arbitrary, $\hat{\nu}$ is a centered Gaussian distribution as defined in 456Ab. Of course it is the only such distribution on $\mathbb{R}^J$ for which T is inverse-measure-preserving.

(ii) Now suppose that J is countable. Then $\mathbb{R}^J$ is is Polish (4A2Qc), so ν is a Borel measure and $\hat{\nu}$ is a Radon measure (433Cb). $\mathbb{R}^J$ has a countable network consisting of Borel sets, μ is perfect (454A(b-iii)) and totally finite, and T is measurable (418Bd), so μT^{-1} is a Radon measure (451N). Thus $\hat{\nu}$ and μT^{-1} are Radon measures agreeing on the Borel sets and must be equal.

(b) The point is that $\mu f^{-1} = \nu f^{-1}$ for every continuous linear functional $f : \mathbb{R}^I \to \mathbb{R}$. **P** By (a), μf^{-1} and νf^{-1} are Radon measures on $\mathbb{R}$, and by the definition of 'Gaussian distribution' each is either a normal distribution with expectation zero, or is concentrated at 0. By 4A4Be, we can express f in the form $f(x) = \sum_{i \in I} \beta_i x(i)$ for every $x \in \mathbb{R}^I$, where $\{i : \beta_i \neq 0\}$ is finite. In this case

$$\begin{aligned}\int t^2 (\mu f^{-1})(dt) &= \int f(x)^2 \mu(dx) = \sum_{i,j \in I} \beta_i \beta_j \int x(i)x(j)\mu(dx) \\ &= \sum_{i,j \in I} \beta_i \beta_j \int x(i)x(j)\nu(dx) = \int t^2 (\nu f^{-1})(dt)\end{aligned}$$

because μ and ν have the same covariance matrices. But this means that μf^{-1} and νf^{-1} have the same variance; if this is zero, they both give measure 1 to $\{0\}$; otherwise, they are normal distributions with the same expectation and the same variance, so again are equal. **Q**

By 454M, $\mu = \nu$.

(c) Being a completion regular quasi-Radon probability measure (415E), $\mu_G^{(I)}$ is the completion of a Baire probability measure on $\mathbb{R}^I$. If $f : \mathbb{R}^I \to \mathbb{R}$ is a continuous linear functional, then it is expressible in the

form $f(z) = \sum_{i\in I} \beta_i z(i)$, where $J = \{i : \beta_i \neq 0\}$ is finite. I need to show that f is either zero a.e. or a normal random variable with expectation 0. If $J = \emptyset$ then $f = 0$ everywhere and we can stop. Otherwise, $f = \sum_{i\in J} \beta_i \pi_i$, where $\pi_i(x) = x(i)$ for $i \in I$, $x \in \mathbb{R}^I$. Now, with respect to the measure $\mu_G^{(I)}$, $\langle \pi_i \rangle_{i\in J}$ is an independent family of normal random variables with zero expectation (272G). So $\langle \beta_i \pi_i \rangle_{i\in J}$ is independent (272E), and $\beta_i \pi_i$ is normal for $i \in J$ (274Ae). By 274B, $f = \sum_{i\in J} \beta_i \pi_i$ is normal, and of course it has zero expectation. As f is arbitrary, $\mu_G^{(I)}$ is a centered Gaussian distribution.

We have

$$\int x(i)x(i)\mu_G^{(I)}(dx) = \int t^2 \mu_G(dt) = 1$$

for $i \in I$, and

$$\int x(i)x(j)\mu_G^{(I)}(dx) = \int t\mu_G(dt) \cdot \int t\mu_G(dt) = 0$$

if $i, j \in I$ are distinct. So the covariance matrix of $\mu_G^{(J)}$ is the identity matrix. By (b), it is the only centered Gaussian distribution with this covariance matrix.

(d)(i) It follows from (c) and (a) that if $\mu = \mu_G^{(\mathbb{N})} T^{-1}$, where $T : \mathbb{R}^{\mathbb{N}} \to \mathbb{R}^I$ is a continuous linear operator, then μ is a centered Gaussian distribution.

(ii) Now suppose that μ is a centered Gaussian distribution on $\mathbb{R}^I$. Set $\pi_i(x) = x(i)$ for $i \in I$ and $x \in \mathbb{R}^I$; for $i \in I$, set $u_i = \pi_i^\bullet$ in $L^2 = L^2(\mu)$. By 4A4Jg, there is a countable orthonormal family $\langle v_j \rangle_{j\in J}$ in L^2 such that every v_j is a linear combination of the u_i, and every u_i is a linear combination of the v_j. We may suppose that $J \subseteq \mathbb{N}$. For $i \in I$, express u_i as $\sum_{j\in J} \alpha_{ij} v_j$, where $\{j : \alpha_{ij} \neq 0\}$ is finite. Define $T : \mathbb{R}^{\mathbb{N}} \to \mathbb{R}^I$ by setting $(Tz)(i) = \sum_{j\in J} \alpha_{ij} z(j)$ for every $z \in \mathbb{R}^{\mathbb{N}}$, $i \in I$. Then T is a continuous linear functional. Set $\nu = \mu_G^{(\mathbb{N})} T^{-1}$, so that ν is a centered Gaussian distribution on $\mathbb{R}^I$, by (a). Because $\mathbb{R}^I$ is Polish, both μ and ν must be Radon measures.

(iii) Now μ and ν have the same covariance matrices. **P** If $i, i' \in I$ then

$$\begin{aligned}\int x(i)x(i')\mu(dx) &= (u_i|u_{i'}) = \sum_{j,j'\in J} \alpha_{ij}\alpha_{i'j'}(v_j|v_{j'}) \\ &= \sum_{j\in J} \alpha_{ij}\alpha_{i'j} = \sum_{j,j'\in J} \alpha_{ij}\alpha_{i'j'} \int z(j)z(j')\mu_G^{(\mathbb{N})}(dz) \\ &= \int (Tz)(i)(Tz)(i')\mu_G^{(\mathbb{N})}(dz) = \int x(i)x(i')\nu(dx). \ \textbf{Q}\end{aligned}$$

By (b), $\mu = \nu$ is of the required form.

(e) We must first confirm that ν is the completion of a Baire measure. **P** If we write $\mathcal{Ba}(\mathbb{R}^{I_j})$ for the Baire σ-algebra of $\mathbb{R}^{I_j}$, then each ν_j is the completion of its restriction $\nu_j \restriction \mathcal{Ba}(\mathbb{R}^{I_j})$, so ν is also the product of the measures $\nu_j \restriction \mathcal{Ba}(\mathbb{R}^{I_j})$ (254I), and is therefore the completion of its restriction to $\widehat{\bigotimes}_{j\in J} \mathcal{Ba}(\mathbb{R}^{I_j})$ (254Ff). But as $\mathcal{Ba}(\mathbb{R}^{I_j}) = \widehat{\bigotimes}_{i\in I_j} \mathcal{Ba}(\mathbb{R})$ for every j (4A3Na), $\widehat{\bigotimes}_{j\in J} \mathcal{Ba}(\mathbb{R}^{I_j})$ can be identified with $\widehat{\bigotimes}_{i\in I} \mathcal{Ba}(\mathbb{R}) = \mathcal{Ba}(\mathbb{R}^I)$, so that ν is indeed the completion of $\nu \restriction \mathcal{Ba}(\mathbb{R}^I)$. **Q**

Now suppose that $f : \mathbb{R}^I \to \mathbb{R}$ is a continuous linear functional. Then we can express f in the form $f(x) = \sum_{i\in K} \alpha_i x(i)$ for every $x \in \mathbb{R}^I$, where $K \subseteq I$ is finite. Set $L = \{j : K \cap I_j \neq \emptyset\}$ and $K_j = K \cap I_j$ for $j \in L$, so that L and every K_j are finite; for $j \in L$, $x \in \mathbb{R}^I$ set $f_j(x) = \sum_{i\in K_j} \alpha_i x(i)$. Now $f = \sum_{j\in L} f_j$.

If we set $g_j(y) = \sum_{i\in K_j} \alpha_i y(i)$ for $y \in \mathbb{R}^{I_j}$, then g_j is either zero a.e. or a normal random variable with respect to the probability measure ν_j. Since

$$\nu\{x : f_j(x) \leq \alpha\} = \nu\{x : g_j(x \restriction I_j) \leq \alpha\} = \nu_j\{y : g_j(y) \leq \alpha\}$$

for every $\alpha \in \mathbb{R}$, f_j (regarded as a random variable on $(\mathbb{R}^I, \nu)$) has the same distribution as g_j (regarded as a random variable on $(\mathbb{R}^{I_j}, \nu_j)$). This is true for every $j \in L$. Moreover, the different f_j, as j runs over L, are independent. So $f = \sum_{j\in L} f_j$ is the sum of independent random variables which are all either normal or essentially constant. By 274B again, f also is either normal or essentially constant. And of course its expectation is zero. As f is arbitrary, this shows that ν is a centered Gaussian distribution.

(f) Set $Tx = -x$ for $x \in \mathbb{R}^I$, so that T is a continuous linear operator and we have a unique centered Gaussian distribution ν on $\mathbb{R}^I$ such that T is inverse-measure-preserving for μ and ν, by (a). For any i, $j \in I$,

$$\int x(i)x(j)\nu(dx) = \int (Tx)(i)(Tx)(j)\mu(dx) = \int x(i)x(j)\mu(dx),$$

so μ and ν have the same covariance matrices and are equal, by (b). Accordingly

$$\mu(-E) = \mu T^{-1}[E] = \nu E = \mu E$$

whenever μ measures E.

456C Lemma Let I be a finite set and μ a centered Gaussian distribution on $\mathbb{R}^I$. Suppose that $\gamma \geq 0$ and $\alpha = \mu\{x : \sup_{i\in I} |x(i)| \geq \gamma\}$. Then $\mu\{x : \sup_{i\in I} |x(i)| \geq \frac{1}{2}\gamma\} \geq 2\alpha(1-\alpha)^3$.

proof The case $\gamma = 0$, $\alpha = 1$ is trivial; suppose that $\gamma > 0$. We may suppose that I has a total order $\leq$. Give $\mathbb{R}^{I\times 4} \cong (\mathbb{R}^I)^4$ the product λ of four copies of μ; then λ is a centered Gaussian distribution (456Be). Define $T : \mathbb{R}^{I\times 4} \to \mathbb{R}^I$ by setting $(Ty)(i) = \frac{1}{2}\sum_{r=0}^3 y(i,r)$ for $i \in I$, $y \in \mathbb{R}^{I\times 4}$; then λT^{-1} is a centered Gaussian distribution on $\mathbb{R}^I$ (456Ba). Now λT^{-1} has the same covariance matrix as μ. **P** If i, $j \in I$ then

$$\begin{aligned}\int x(i)x(j)(\lambda T^{-1})(dx) &= \int (Ty)(i)(Ty)(j)\lambda(dy) = \frac{1}{4}\sum_{r=0}^3\sum_{s=0}^3 \int y(i,r)y(j,s)\lambda(dy)\\ &= \frac{1}{4}\sum_{r=0}^3 \int y(i,r)y(j,r)\lambda(dy) = \frac{1}{4}\sum_{r=0}^3 \int x(i)x(j)\mu(dx)\end{aligned}$$

(because the map $y \mapsto \langle y(i,r)\rangle_{i\in I} : \mathbb{R}^{I\times 4} \to \mathbb{R}^I$ is inverse-measure-preserving for each r)

$$= \int x(i)x(j)\mu(dx).$$ **Q**

So $\lambda T^{-1} = \mu$, by 456Bb.

Define

$$E_{ir} = \{y : y \in \mathbb{R}^{I\times 4},\ |y(i,r)| \geq \gamma\}$$

for $r < 4$ and $i \in I$, and

$$E_r = \bigcup_{i\in I} E_{ir}$$

for $r < 4$, so that

$$\lambda E_r = \lambda\{y : \sup_{i\in I} |y(i,r)| \geq \gamma\} = \mu\{x : \sup_{i\in I} |x(i)| \geq \gamma\} = \alpha.$$

Set $E'_r = E_r \setminus \bigcup_{s\neq r} E_s$, so that

$$\begin{aligned}\lambda E'_r &= \lambda\{y : \sup_{i\in I} |y(i,r)| \geq \gamma,\ \sup_{i\in I} |y(i,s)| < \gamma \text{ for } s \neq r)\\ &= \lambda\{y : \sup_{i\in I} |y(i,r)| \geq \gamma\} \cdot \prod_{s\neq r} \lambda\{y : \sup_{i\in I} |y(i,s)| < \gamma\}\end{aligned}$$

(because these are independent events)

$$= \alpha(1-\alpha)^3.$$

Next, for $i \in I$ and $r < 4$, set $E'_{ir} = E_{ir} \setminus (\bigcup_{j<i} E_{jr} \cup \bigcup_{s\neq r} E_s)$, so that $E'_r = \bigcup_{i\in I} E'_{ir}$. Observe that $\langle E'_{ir}\rangle_{i\in I, r<4}$ is disjoint. Set

$$F_{ir} = \{y : y \in E'_{ir},\ y(i,r)\textstyle\sum_{s\neq r} y(i,s) \geq 0\}.$$

Then $\nu F_{ir} \geq \frac{1}{2}\nu E'_{ir}$. **P** We can think of $\mathbb{R}^{I\times 4}$ as a product $\mathbb{R}^J \times \mathbb{R}^K$, where $J = I \times \{r\}$ and $K = I \times (4 \setminus \{r\})$. In this case, λ becomes identified with a product $\lambda_J \times \lambda_K$, where λ_J and λ_K are centered Gaussian distributions on $\mathbb{R}^J$ and $\mathbb{R}^K$ respectively, and E'_{ir} is of the form $V \times W$, where

$$V = \{v : v \in \mathbb{R}^J, |v(i,r)| \geq \gamma, |v(j,r)| < \gamma \text{ for } j < i\},$$

$$W = \{w : w \in \mathbb{R}^K, |w(j,s)| < \gamma \text{ for every } j \in I, s \neq r\}.$$

In the same representation, F_{ir} becomes $(V^+ \times W^+) \cup (V^- \times W^-)$, where

$$V^+ = \{v : v \in V, v(i,r) \geq \gamma\}, \quad V^- = \{v : v \in V, v(i,r) \leq -\gamma\},$$

$$W^+ = \{w : w \in W, \textstyle\sum_{r \neq s} w(i,s) \geq 0\}, \quad W^- = \{w : w \in W, \textstyle\sum_{r \neq s} w(i,s) \leq 0\}.$$

By 456Bf, $\lambda_J V^+ = \lambda_J V^-$ and $\lambda_K W^+ = \lambda_K W^-$; since $V^- = V \setminus V^+$, while $W^+ \cup W^- = W$, we have

$$\lambda_J V^+ = \lambda_J V^- = \tfrac{1}{2}\lambda_J V, \quad \lambda_K W^+ = \lambda_K W^- \geq \tfrac{1}{2}\lambda_K W.$$

But this means that

$$\begin{aligned}\lambda F_{ir} &= \lambda(V^+ \times W^+) + \lambda(V^- \times W^-)\\ &= \lambda_J V^+ \cdot \lambda_K W^+ + \lambda_J V^- \cdot \lambda_K W^- \geq \tfrac{1}{2}\lambda_J V \cdot \lambda_K W = \tfrac{1}{2}\lambda E'_{ir},\end{aligned}$$

as claimed. **Q**

At this point, observe that if $y \in F_{ir}$ then $|\sum_{s=0}^4 y(i,s)| \geq |y(i,r)| \geq \gamma$. So

$$\begin{aligned}\mu\{x : \sup_{i\in I} |x(i)| \geq \tfrac{1}{2}\gamma\}) &= \lambda T^{-1}[\{x : \sup_{i\in I} |x(i)| \geq \tfrac{1}{2}\gamma\})]\\ &= \lambda\{y : \sup_{i\in I} |\frac{1}{2}\sum_{r=0}^3 y(i,r)| \geq \tfrac{1}{2}\gamma\})\\ &= \lambda\{y : \sup_{i\in I} |\sum_{r=0}^3 y(i,r)| \geq \gamma)\\ &\geq \lambda(\bigcup_{i\in I, r<4} F_{ir}) = \sum_{i\in I, r<4} \lambda F_{ir}\\ &\geq \frac{1}{2}\sum_{r<4}\sum_{i\in I} \lambda E'_{ir} \geq \frac{1}{2}\sum_{r<4} \lambda E'_r = 2\alpha(1-\alpha)^3,\end{aligned}$$

which is what we set out to prove.

456D The support of a Gaussian distribution: Proposition Let I be a set and μ a centered Gaussian distribution on $\mathbb{R}^I$. Write Z for the set of those $x \in \mathbb{R}^I$ such that $f(x) = 0$ whenever $f : \mathbb{R}^I \to \mathbb{R}$ is a continuous linear functional and $f = 0$ a.e. Then Z is a self-supporting closed linear subspace of $\mathbb{R}^I$ with full outer measure. If I is countable it is the support of μ.

proof (a) Being the intersection of a family of closed linear subspaces, of course Z is a closed linear subspace.

(b) Z is of full outer measure. **P** Let $F \subseteq \mathbb{R}^I$ be a non-negligible zero set. Let $J \subseteq I$ be a countable set such that F is determined by coordinates in J. For $i \in I$, $x \in X$ set $\pi_i(x) = x(i)$; then each π_i is either normally distributed or zero almost everywhere, so is square-integrable; set $u_i = \pi_i^\bullet$ in $L^2 = L^2(\mu)$. Let $\langle v_k\rangle_{k\in K}$ be a countable orthonormal family in L^2 such that every v_k is a linear combination of the u_i, for $i \in J$, and every u_i, for $i \in J$, is a linear combination of the v_k (4A4Jg). Extend $\langle v_k\rangle_{k\in K}$ to a Hamel basis $\langle v_l\rangle_{l\in L}$ of L^2. For every $i \in I$, we can express u_i as $\sum_{l\in L} \alpha_{il} v_l$, where $\{l : \alpha_{il} \neq 0\}$ is finite; and the construction ensures that $\alpha_{il} = 0$ if $i \in J$ and $l \in L \setminus K$.

Consider the linear operator $T_0 : \mathbb{R}^K \to \mathbb{R}^J$ defined by setting $(T_0 z)(i) = \sum_{k\in K} \alpha_{ik} z(k)$ for $z \in \mathbb{R}^K$ and $i \in J$. If we give $\mathbb{R}^K$ the product measure $\mu_G^{(K)}$, then the image measure $\mu_G^{(K)} T_0^{-1}$ is a Gaussian distribution (456Ba), with covariance matrix

$$\begin{aligned}\sigma_{ii'} &= \int x(i)x(i')(\mu_G^{(K)}T_0^{-1})dx = \int (T_0z)(i)(T_0z)(i')\mu_G^{(K)}(dz)\\ &= \sum_{k,k'\in K}\alpha_{ik}\alpha_{i'k'}z(k)z(k')\mu_G^{(K)}(dz) = \sum_{k\in K}\alpha_{ik}\alpha_{i'k}\\ &= \sum_{k,k'\in K}\alpha_{ik}\alpha_{i'k}(v_k|v_{k'}) = (u_i|u_{i'}) = \int x(i)x(i')\mu(dx).\end{aligned}$$

But this means that $\mu_G^{(K)}T_0^{-1}$ has the same covariance matrix as $\mu\tilde{\pi}_J^{-1}$, where $\tilde{\pi}_Jx = x\restriction J$ for $x \in \mathbb{R}^I$. Since this also is a centered Gaussian distribution, the two measures must be equal (456Bb). We know that $\tilde{\pi}_J[F]$ has non-zero measure, so there is a $z_0 \in \mathbb{R}^K$ such that $T_0z_0 \in \tilde{\pi}_J[F]$. Extend z_0 arbitrarily to $z_1 \in \mathbb{R}^L$.

Set $x_1(i) = \sum_{l\in L}\alpha_{il}z_1(l)$ for $i \in I$. Then $\tilde{\pi}_Jx_1 = T_0z_0 \in \tilde{\pi}_J[F]$, so $x_1 \in F$, because F is determined by coordinates in J. If a continuous linear functional $f : \mathbb{R}^I \to \mathbb{R}$ is zero a.e., it can be expressed in the form $f(x) = \sum_{i\in I}\beta_ix(i)$ where $\{i : \beta_i \neq 0\}$ is finite (4A4Be). In this case,

$$0 = f^\bullet = \textstyle\sum_{i\in I}\beta_iu_i = \sum_{l\in L}\sum_{i\in I}\beta_i\alpha_{il}v_l$$

in L^2. Since $\langle v_l\rangle_{l\in L}$ is linearly independent, $\sum_{i\in I}\beta_i\alpha_{il} = 0$ for every $l \in L$. But this means that

$$f(x_1) = \textstyle\sum_{i\in I,l\in L}\beta_i\alpha_{il}z_1(l) = 0.$$

As f is arbitrary, $x_1 \in Z$ and $Z \cap F \neq \emptyset$. As F is arbitrary, and μ is inner regular with respect to the zero sets, Z has full outer measure. **Q**

(c) Z is self-supporting. **P** If $W \subseteq \mathbb{R}^I$ is an open set meeting Z, there is an open set V, depending on coordinates in a finite set $J \subseteq I$, such that $V \subseteq W$ and $V \cap Z \neq \emptyset$. Write $\tilde{\pi}_J(x) = x\restriction J$ for $x \in \mathbb{R}^I$, and ν_J for the image measure $\mu\tilde{\pi}_J^{-1}$ on $\mathbb{R}^J$; by 456Ba, this is a centered Gaussian distribution. By 456Bd, there is a continuous linear operator $T : \mathbb{R}^{\mathbb{N}} \to \mathbb{R}^J$ such that $\nu_J = \mu_G^{(\mathbb{N})}T^{-1}$. Since the support of μ_G is $\mathbb{R}$, the support of $\mu_G^{(\mathbb{N})}$ is $\mathbb{R}^{\mathbb{N}}$ (417E(iv), or otherwise), and the support of ν_J is $Z_1 = \overline{T[\mathbb{R}^{\mathbb{N}}]}$ (411Ne).

Write Q for the set of linear functionals $g : \mathbb{R}^J \to \mathbb{R}$ (necessarily continuous) which are zero on Z_1. If $g \in Q$, then $gT = 0$, so $g = 0$ ν_J-a.e. and $g\tilde{\pi}_J = 0$ μ-a.e. This means that $g\tilde{\pi}_J(x) = 0$ for every $x \in Z$, that is, $g(y) = 0$ for every $y \in \tilde{\pi}_J[Z]$. Because Z_1 is a linear subspace of $\mathbb{R}^J$, this is enough to show that $\tilde{\pi}_J[Z] \subseteq Z_1$.

Now recall that $V \cap Z \neq \emptyset$ so $Z_1 \cap \tilde{\pi}_J[V] \neq \emptyset$, while $V = \tilde{\pi}_J^{-1}[\tilde{\pi}_J[V]]$. Since $\tilde{\pi}_J$ is an open map (4A2B(f-i)), $\tilde{\pi}_J[V]$ is open and

$$\mu^*(W \cap Z) = \mu W \geq \mu V = \nu_J\tilde{\pi}_J[V] > 0,$$

because Z_1 is the support of ν_J. **Q**

(d) If I is countable, μ is a topological measure so measures Z, and Z is the support of μ.

456E Remarks (a) In the context of 456D, I will call Z the **support** of the centered Gaussian distribution μ, even though μ need not be a topological measure, so the definition 411Nb is not immediately applicable. In 456L we shall see that Z really is the support of a canonical extension of μ.

(b) It is worth making one elementary point at once. If I and J are sets, μ and ν are centered Gaussian distributions on $\mathbb{R}^I$ and $\mathbb{R}^J$ respectively with supports Z and Z', and $T : \mathbb{R}^I \to \mathbb{R}^J$ is an inverse-measure-preserving continuous linear operator, then $Tz \in Z'$ for every $z \in Z$. **P** If $g : \mathbb{R}^J \to \mathbb{R}$ is a continuous linear functional which is zero ν-a.e., then $gT : \mathbb{R}^I \to \mathbb{R}$ is a continuous linear functional which is zero μ-a.e., so $g(Tz) = (gT)(z) = 0$. **Q**

456F Universal Gaussian distributions: Definition A centered Gaussian distribution on $\mathbb{R}^I$ is **universal** if its covariance matrix $\langle\sigma_{ij}\rangle_{i,j\in I}$ is the inner product for a Hilbert space structure on I. (See 456Xd.)

456G Proposition Let I be any set, and μ a centered Gaussian distribution on I. Then there are a set J, a universal centered Gaussian distribution ν on $\mathbb{R}^J$, and a continuous inverse-measure-preserving linear operator $T : \mathbb{R}^J \to \mathbb{R}^I$.

proof (a) Set $L^2 = L^2(\mu)$. Then for any finite $K \subseteq L^2$ there is a centered Gaussian distribution μ_K on $\mathbb{R}^K$ such that $\int x(u)x(v)\mu(dx) = (u|v)$ for all u, $v \in K$. **P** If $K = \emptyset$ or $K = \{0\}$ this is trivial, as we take μ to be the trivial distribution concentrated at 0. Otherwise, let $\langle w_i\rangle_{i<n}$ be an orthonormal basis for the linear subspace of L^2 generated by K. For each $u \in K$, express it as $\sum_{i=0}^{n-1} \alpha_{ui} w_i$. Define $T : \mathbb{R}^n \to \mathbb{R}^K$ by setting $(Tz)(u) = \sum_{i=0}^{n-1} \alpha_{ui} z(i)$ for $z \in \mathbb{R}^n$ and $u \in K$. Set $\mu_K = \mu_G^{(n)} T^{-1}$. Then μ_K is a centered Gaussian distribution, by 456Ba, and its covariance matrix is given by

$$\begin{aligned}\int x(u)x(v)\mu_K(dx) &= \int (Ty)(u)(Ty)(v)\mu_G^{(n)}(dy)\\ &= \sum_{i=0}^{n-1}\sum_{j=0}^{n-1} \alpha_{ui}\alpha_{vj} \int y(i)y(j)\mu_G^{(n)}(dy)\\ &= \sum_{i=0}^{n-1}\sum_{j=0}^{n-1} \alpha_{ui}\alpha_{vj}(w_i|w_j) = (u|v)\end{aligned}$$

for all u, $v \in K$. So μ_K is the distribution we seek. **Q**

(b) If $K \subseteq L^2$ is finite and $L \subseteq K$, then $\mu_L = \mu_K \pi_{KL}^{-1}$, where $\pi_{KL}(x) = x\restriction L$ for $x \in \mathbb{R}^K$. **P** Since $\mu_K \pi_{KL}^{-1}$ is a centered Gaussian distribution, all we have to do is to check its covariance matrix. But if u, $v \in L$ then

$$\begin{aligned}\int y(u)y(v)(\mu_K\pi_{KL}^{-1})(dy) &= \int (\pi_{KL}x)(u)(\pi_{KL}x)(v)\mu_K(dx)\\ &= \int x(u)x(v)\mu_K(dx) = (u|v) = \int y(u)y(v)\mu_L(dy).\end{aligned}$$

By 456Bb, $\mu_L = \mu_K\pi_{KL}^{-1}$. **Q**

(c) By 454G, there is a Baire measure ν' on $\mathbb{R}^{L^2}$ such that $\nu'\tilde{\pi}_K^{-1}[E] = \mu_K E$ for every finite $K \subseteq L^2$ and every Borel set $E \subseteq \mathbb{R}^K$, where $\tilde{\pi}_K(x) = x\restriction K$ for $x \in \mathbb{R}^{L^2}$. Take ν to be the completion of ν'. Then $\tilde{\pi}_K$ is inverse-measure-preserving for ν and μ_K, for every finite $K \subseteq L^2$. If $f : \mathbb{R}^{L^2} \to \mathbb{R}$ is a continuous linear functional, there are a finite $K \subseteq L^2$ and a linear functional $g : \mathbb{R}^K \to \mathbb{R}$ such that $f = \tilde{\pi}_K g$, so that

$$\nu\{x : f(x) \leq \alpha\} = \mu_K\{x : g(x) \leq \alpha\}$$

for every α, and f and g have the same distribution; as g is either normal with zero expectation or zero a.e., so is f. As f is arbitrary, ν is a centered Gaussian distribution.

(d) ν is universal. **P** If u, $v \in L^2$ set $K = \{u, v\}$. Then

$$\begin{aligned}\int x(u)x(v)\nu(dx) &= \int (\tilde{\pi}_K x)(u)(\tilde{\pi}_K x)(v)\nu(dx)\\ &= \int y(u)y(v)\mu_K(dy) = (u|v).\end{aligned}$$

Thus the covariance matrix of ν is just the inner product of the standard Hilbert space structure of L^2. **Q**

(e) For $i \in I$, let $u_i \in L^2$ be the equivalence class of the square-integrable function $x \mapsto x(i) : \mathbb{R}^I \to \mathbb{R}$. Define $T : \mathbb{R}^{L^2} \to \mathbb{R}^I$ by setting $(Ty)(i) = y(u_i)$ for every $i \in I$, $y \in \mathbb{R}^{L^2}$. Then there is a centered Gaussian distribution μ' on $\mathbb{R}^I$ such that T is inverse-measure-preserving for ν and μ'. Now the covariance matrix of μ' is defined by

$$\int x(i)x(j)\mu'(dx) = \int (Ty)(i)(Ty)(j)\nu(dy) = \int y(u_i)y(u_j)\nu(dy)$$
$$= (u_i|u_j) = \int x(i)x(j)\mu(dx)$$

for all i, $j \in I$. So μ and μ' are equal and T is inverse-measure-preserving for ν and μ.

456H Lemma Let μ be a universal centered Gaussian distribution on $\mathbb{R}^I$; give I a corresponding Hilbert space structure such that $\int x(i)x(j)\mu(dx) = (i|j)$ for all i, $j \in I$. Let $F \subseteq \mathbb{R}^I$ be a set determined by coordinates in J, where $J \subseteq I$ is a closed linear subspace for the Hilbert space structure of I. Let W be the union of all the open subsets of $\mathbb{R}^I$ which meet F in a negligible set, and W' the union of the open subsets of $\mathbb{R}^I$ which meet F in a negligible set and are determined by coordinates in J. If $F \subseteq W$ then $F \subseteq W'$.

proof (a) Let Z be the support of μ in the sense of 456D. We need to know that Z is just the set of all linear functionals from I to $\mathbb{R}$. **P** If $K \subseteq I$ is finite and $\langle \alpha_i \rangle_{i\in K} \in \mathbb{R}^K$ and $f(x) = \sum_{i\in I} \alpha_i x(i)$ for $x \in \mathbb{R}^I$, then

$$\|f\|_2^2 = \textstyle\sum_{i,j\in K} \alpha_i\alpha_j(i|j) = \|\sum_{i\in K} \alpha_i i\|^2.$$

So, for $x \in \mathbb{R}^I$,

$$\begin{aligned} x \in Z &\iff f(x) = 0 \text{ whenever } f \in (\mathbb{R}^I)^* \text{ and } \|f\|_2 = 0 \\ &\iff \sum_{i\in K} \alpha_i x(i) = 0 \text{ whenever } K \subseteq I \text{ is finite and } \sum_{i\in K} \alpha_i i = 0 \text{ in } I \\ &\iff x : I \to \mathbb{R} \text{ is linear. } \textbf{Q} \end{aligned}$$

(b) Let $J^\perp$ be the orthogonal complement of J in I, so that $I = J \oplus J^\perp$ (4A4Je). Give $\mathbb{R}^J$ and $\mathbb{R}^{J^\perp}$ the centered Gaussian distributions μ_J, $\mu_{J^\perp}$ induced by μ and the projections $x \mapsto x\restriction J$, $x \mapsto x\restriction J^\perp$. Then the product measure λ on $\mathbb{R}^J \times \mathbb{R}^{J^\perp}$ is also a centered Gaussian distribution (456Be). Define $T : \mathbb{R}^J \times \mathbb{R}^{J^\perp} \to \mathbb{R}^I$ by setting $T(u,v)(j+k) = u(j) + v(k)$ whenever $j \in J$, $k \in J^\perp$, $u \in \mathbb{R}^J$ and $v \in \mathbb{R}^{J^\perp}$. Then T is inverse-measure-preserving for λ and μ. **P** T is a continuous linear operator so we have a centered Gaussian distribution μ' on $\mathbb{R}^I$ such that T is inverse-measure-preserving for λ and μ'. If j, $j' \in J$ and k, $k' \in J^\perp$,

$$\begin{aligned} \int x(j+k)x(j'+k')\mu'(dx) &= \int T(u,v)(j+k)T(u,v)(j'+k')\lambda(d(u,v)) \\ &= \int (u(j)+v(k))(u(j')+v(k'))\lambda(d(u,v)) \\ &= \int u(j)u(j')\mu_J(du) + \int v(k)v(k')\mu_{J^\perp}(dv) \\ &= \int x(j)x(j')\mu(dx) + \int x(k)x(k')\mu(dx) \\ &= (j|j') + (k|k') = (j+k|j'+k') \\ &= \int x(j+k)x(j'+k')\mu(dx). \end{aligned}$$

Thus μ and μ' have the same covariance matrix and are equal, and T is inverse-measure-preserving for λ and μ. **Q**

(c) Take any $z \in W \cap Z$. Then there is an open set V, determined by coordinates in a finite set $K_0 \subseteq I$, such that $z \in V$ and $\mu(V \cap F) = 0$. Let $\epsilon > 0$ be such that $y \in V$ whenever $x \in \mathbb{R}^I$ and $|x(i) - z(i)| < 2\epsilon$ for every $i \in K_0$. Express each $k \in K_0$ as $k' + k''$ where $k' \in J$ and $k'' \in J^\perp$. Set

$$V' = \{x : x \in \mathbb{R}^I, |x(k') - z(k')| < \epsilon \text{ for every } k \in K_0\}.$$

Then V' is an open set, determined by coordinates in J, and contains z. Also $\mu(V' \cap F) = 0$. **P** Set $V'' = \{x : x \in \mathbb{R}^I, |x(k'') - z(k'')| < \epsilon \text{ for every } k \in K_0\}$. Then $V \supseteq V' \cap V'' \cap Z$. Since Z has full outer measure (456D),

$$\mu(V' \cap V'' \cap F) = \mu^*(V' \cap V'' \cap F \cap Z) \leq \mu(V \cap F) = 0.$$

Now

$$\begin{aligned} 0 = \mu(V' \cap V'' \cap F) &= \lambda T^{-1}[V' \cap F \cap V''] \\ &= \lambda\{(x\restriction J, x\restriction J^\perp) : x \in V' \cap F \cap V''\} \end{aligned}$$

(because $V' \cap F \cap V''$ is determined by coordinates in $J \cup J^\perp$)

$$= \mu_J\{x\restriction J : x \in V' \cap F\} \cdot \mu_{J^\perp}\{x\restriction J^\perp : x \in V''\}$$

because $V' \cap F$ is determined by coordinates in J, while V'' is determined by coordinates in $J^\perp$. However, $z \in V''$, and $z\restriction J^\perp$ belongs to the support Z' of $\mu_{J^\perp}$, by 456Eb; since Z' is self-supporting, and $\{x\restriction J^\perp : x \in V''\}$ is open, $\mu_{J^\perp}\{x\restriction J^\perp : x \in V''\} > 0$. We conclude that

$$0 = \mu_J\{x\restriction J : x \in V' \cap F\} = \mu(V' \cap F). \ \textbf{Q}$$

(d) This shows that $z \in W'$. As z is arbitrary, $W \cap Z \subseteq W'$.

? Suppose, if possible, that there is a point $z_0 \in F \setminus W'$. If i, $j \in J$ and $\alpha \in \mathbb{R}$, then

$$\{x : x(i+j) \neq x(i) + x(j)\}, \quad \{x : x(\alpha i) \neq \alpha x(i)\}$$

are negligible open sets determined by coordinates in J, so are included in W' and do not contain z_0. Thus $z_0\restriction J : J \to \mathbb{R}$ is linear. Let $z : I \to \mathbb{R}$ be a linear functional extending $z_0\restriction J$. Then $z \in Z$ and $z\restriction J = z_0\restriction J$; as both F and W' are determined by coordinates in J, $z \in F \setminus W'$. But this means that $z \in Z \cap W \setminus W'$, which is impossible. **X**

So $F \subseteq W'$, as claimed.

456I Cluster sets: Lemma Let I be a countable set, $n \geq 1$ an integer and μ a centered Gaussian distribution on $\mathbb{R}^{I \times n}$. For $\epsilon > 0$ set

$$I_\epsilon = \{i : i \in I, \int |x(i,r)|^2 \mu(dx) \leq \epsilon^2 \text{ for every } r < n\};$$

suppose that no I_ϵ is empty.

(a) There is a closed set $F \subseteq \mathbb{R}^n$ such that

$$F = \textstyle\bigcap_{\epsilon>0} \overline{\{\langle x(i,r)\rangle_{r<n} : i \in I_\epsilon\}}$$

for almost every $x \in \mathbb{R}^{I \times n}$.

(b) If $z \in F$ and $-1 \leq \alpha \leq 1$, then $\alpha z \in F$.

(c) If F is bounded, then there is some $\epsilon > 0$ such that $\sup_{i \in I_\epsilon, r<n} |x(i,r)| < \infty$ for almost every $x \in \mathbb{R}^{I \times n}$.

proof (a)(i) For $x \in \mathbb{R}^{I \times n}$, $i \in I$ set $S_i(x) = \langle x(i,r)\rangle_{r<n} \in \mathbb{R}^n$. For $x \in \mathbb{R}^{I \times n}$ set

$$F_x = \textstyle\bigcap_{\epsilon>0} \overline{\{S_i x : i \in I_\epsilon\}},$$

so that F_x is a closed subset of $\mathbb{R}^n$. For $A \subseteq \mathbb{R}^n$ set $E_A = \{x : x \in \mathbb{R}^{I \times n}, A \cap F_x \neq \emptyset\}$.

(ii) By 456Bd, there is a continuous linear operator $T : \mathbb{R}^{\mathbb{N}} \to \mathbb{R}^{I \times n}$ such that $\mu = \mu_G^{(\mathbb{N})} T^{-1}$. Set $T_i = S_i T$ for $i \in I$; then $T_i : \mathbb{R}^{\mathbb{N}} \to \mathbb{R}^n$ is a continuous linear operator. For $y \in \mathbb{R}^{\mathbb{N}}$, set

$$\tilde{F}_y = F_{T(y)} = \textstyle\bigcap_{\epsilon>0} \overline{\{T_i(y) : i \in I_\epsilon\}}.$$

For $A \subseteq \mathbb{R}^n$ set

$$\tilde{E}_A = T^{-1}[E_A] = \{y : y \in \mathbb{R}^{\mathbb{N}}, A \cap \tilde{F}_y \neq \emptyset\}.$$

(iii) If $K \subseteq \mathbb{R}^n$ is compact, then $\tilde{E}_K$ is a Borel subset of $\mathbb{R}^{\mathbb{N}}$. **P** Let $\mathcal{V}$ be a countable base for the topology of $\mathbb{R}^n$, and for $k \geq 1$ let $\mathcal{V}_k$ be the set of members of $\mathcal{V}$ with diameter at most $1/k$ which meet K. Then $T_i^{-1}[V]$ is a Borel set for every $V \in \mathcal{V}$ and $i \in I$, so

$$E' = \bigcap_{k\geq 1} \bigcup_{V\in\mathcal{V}_k} \bigcup_{i\in I_{1/k}} T_i^{-1}[V]$$

is a Borel set.

If $y \in \tilde{E}_K$, take $k \geq 1$. There is a $z \in \tilde{F}_y \cap K$. Let $V \in \mathcal{V}$ be such that $z \in V$ and $\operatorname{diam} V \leq 1/k$; in this case $V \in \mathcal{V}_k$. Because $z \in \overline{\{T_i(y) : i \in I_{1/k}\}}$, there is an $i \in I_{1/k}$ such that $T_i(y) \in V$. As k is arbitrary, this shows that $y \in E'$; thus $\tilde{E}_K \subseteq E'$.

If $y \notin \tilde{E}_K$, then K is a compact set disjoint from the closed set $\tilde{F}_y$. There is therefore some $\epsilon > 0$ such that $K \cap \overline{\{T_i(y) : i \in I_\epsilon\}} = \emptyset$ (since these form a downwards-directed family of compact sets with empty intersection). Next, there is a $\delta > 0$ such that $B(z,\delta) \cap \overline{\{T_i(y) : i \in I_\epsilon\}} = \emptyset$ for every $z \in K$ (2A2Ed). Let $k \geq 1$ be such that $1/k \leq \min(\epsilon,\delta)$. If $V \in \mathcal{V}_k$ and $i \in I_{1/k}$, there is some $z \in K \cap V$ so $V \subseteq B(z,\delta)$ and $T_i(y) \notin V$. This shows that $y \notin E'$. As y is arbitrary, $E' \subseteq \tilde{E}_K$.

So $\tilde{E}_K = E'$ is a Borel set. **Q**

It follows at once that $\tilde{E}_H$ is a Borel set for every K_σ set H, in particular, for any open or closed set H.

(iv) We need a simple estimate on the coefficients of the linear operators T_i. Let α_{irj} be such that $T_i(y) = \langle \sum_{j=0}^\infty \alpha_{irj} y(j)\rangle_{r<n}$ for $i \in I$, $r < n$ and $y \in \mathbb{R}^{\mathbb{N}}$. (Of course $\{j : \alpha_{irj} \neq 0\}$ is finite for each i and r.) Then

$$\int x(i,r)^2 \mu(dx) = \int T_i(y)(r)^2 \mu_G^{(\mathbb{N})}(dy) = \sum_{j=0}^\infty \alpha_{irj}^2,$$

so $|\alpha_{irj}| \leq \epsilon$ whenever $i \in I_\epsilon$, $r < n$ and $j \in \mathbb{N}$.

(v) Now suppose that $H \subseteq \mathbb{R}^n$ is open, that $K \subseteq H$ is compact, and that $\mu_G^{(\mathbb{N})}\tilde{E}_K > 0$. Then $\mu_G^{(\mathbb{N})}\tilde{E}_H = 1$. **P** Let $\epsilon > 0$. Let $\langle \epsilon_j\rangle_{j\in\mathbb{N}}$ be a sequence of strictly positive real numbers such that $\sum_{j=0}^\infty \epsilon_j \leq \frac{1}{2}\min(\epsilon, \mu_G^{(\mathbb{N})}\tilde{E}_K)$, and for each $j \in \mathbb{N}$ let $\gamma_j \geq 0$ be such that $\mu_G[-\gamma_j,\gamma_j] \geq 1 - \epsilon_j$. Then

$$\tilde{E} = \{y : y \in \tilde{E}_K, |y(j)| \leq \gamma_j \text{ for every } j \in \mathbb{N}\}$$

has measure at least $\mu_G^{(\mathbb{N})}\tilde{E}_K - \sum_{j=0}^\infty \epsilon_j > 0$. By 254Sb, there are an $m \in \mathbb{N}$ and a set $\tilde{E}'$, of measure at least $1 - \frac{1}{2}\epsilon$, such that for every $y' \in \tilde{E}'$ there is a $y \in \tilde{E}$ such that $y(j) = y'(j)$ whenever $j > m$. Set $\tilde{E}'' = \{y : y \in \tilde{E}', |y(j)| \leq \gamma_j \text{ for every } j \in \mathbb{N}\}$, so that $\mu_G^{(\mathbb{N})}\tilde{E}'' \geq 1 - \epsilon$.

Let $\delta > 0$ be such that $z' \in H$ whenever $z \in K$ and $\|z - z'\| \leq 2\delta$. Let $\eta > 0$ be such that $2\eta\sqrt{n}\sum_{j=0}^m \gamma_j \leq \delta$. If $y' \in \tilde{E}''$ and $i \in I_\eta$, there is a $y \in \tilde{E}$ such that $y(j) = y'(j)$ for $j > m$. Also $|y(j) - y'(j)| \leq 2\gamma_j$ for $j \leq m$, so

$$|T_i(y)(r) - T_i(y')(r)| \leq \sum_{j=0}^\infty |\alpha_{irj}||y(j) - y'(j)| \leq \sum_{j=0}^m 2\eta\gamma_j \leq \frac{\delta}{\sqrt{n}}$$

for every $r < n$, and $\|T_i(y) - T_i(y')\| \leq \delta$.

Now $\tilde{F}_y \cap K \neq \emptyset$; take $z \in \tilde{F}_y \cap K$. For every $\zeta > 0$, there is an $i \in I_{\min(\eta,\zeta)}$ such that $\|z - T_i(y)\| \leq \delta$, so that $\|z - T_i(y')\| \leq 2\delta$. This means that $B(x,2\delta) \cap \{T_i(y') : i \in I_\zeta\}$ is not empty. As $B(x,2\delta)$ is compact, it must meet $\tilde{F}_{y'}$. But this means that $H \cap \tilde{F}_{y'} \neq \emptyset$, by the choice of δ. As y' is arbitrary, $\tilde{E}'' \subseteq \tilde{E}_H$, while $\mu_G^{(\mathbb{N})}\tilde{E}'' \geq 1 - \epsilon$.

This works for every $\epsilon > 0$. So $\tilde{E}_H$ is conegligible, as claimed. **Q**

(vi) If $H \subseteq \mathbb{R}^n$ is open and $\mu_G^{(\mathbb{N})}\tilde{E}_H > 0$, then (because H is σ-compact) there is a compact set $K \subseteq H$ such that $\mu_G^{(\mathbb{N})}\tilde{E}_K > 0$, and (e) tells us that $\mu_G^{(\mathbb{N})}\tilde{E}_H = 1$.

Set

$$\mathcal{V}_0 = \{V : V \in \mathcal{V}, \mu_G^{(\mathbb{N})}\tilde{E}_V = 0\} = \{V : V \in \mathcal{V}, \mu_G^{(\mathbb{N})}\tilde{E}_V < 1\}.$$

Then we see that

$$\mathcal{V}_0 = \{V : V \in \mathcal{V}, \tilde{F}_y \cap V = \emptyset\}$$

for almost every $y \in \mathbb{R}^{\mathbb{N}}$, that is,

$$\mathcal{V}_0 = \{V : V \in \mathcal{V}, F_x \cap V = \emptyset\}$$

for almost every $x \in \mathbb{R}^{I\times n}$. But as every F_x is closed, we have $F_x = \mathbb{R}^n \setminus \bigcup \mathcal{V}_0$ for almost every x. So we can set $F = \mathbb{R}^n \setminus \bigcup \mathcal{V}_0$.

(b)(i) Give $\mathbb{R}^{I\times 2n} \cong (\mathbb{R}^{I\times n})^2$ the measure λ corresponding to the product measure $\mu\times\mu$; by 456Be, this is a centered Gaussian distribution. For $(x_1, x_2) \in (\mathbb{R}^{I\times n})^2$, set

$$F'_{x_1x_2} = \textstyle\bigcap_{\epsilon>0} \overline{\{(S_ix_1, S_ix_2) : i \in I_\epsilon\}}.$$

By (a), we have a closed set $F' \subseteq \mathbb{R}^{2n}$ such that $F' = F'_{x_1x_2}$ for almost all x_1, x_2. (Of course $I_\epsilon = \{i : \int |x_j(i,r)|^2\lambda(dx) \leq \epsilon^2$ for every $j \in \{1,2\}$, $r < n\}$ whenever $\epsilon > 0$.)

(ii) Now $(z, 0) \in F'$. **P** Take $x_1 \in \mathbb{R}^{I\times n}$ such that $F = F_{x_1}$ and $E = \{x_2 : F' = F'_{x_1x_2}\}$ is conegligible. (Almost every point of $\mathbb{R}^{I\times n}$ has these properties.) For $k \in \mathbb{N}$, $z \in \overline{\{S_ix_1 : i \in I_{2^{-k}}\}}$; let $i_k \in I_{2^{-k}}$ be such that $\sum_{r<n} |z(r) - x_1(i_k, r)| \leq 2^{-k}$. Next,

$$\textstyle\sum_{k=0}^\infty \sum_{r=0}^{n-1} \int |x(i_k,r)|^2\mu(dx) \leq \sum_{k=0}^\infty 2^{-2k}n < \infty,$$

so $\sum_{k=0}^\infty \sum_{r=0}^{n-1} |x(i_k,r)|^2$ is finite for almost every $x \in \mathbb{R}^I$, and there must be an $x_2 \in E$ such that $\sum_{k=0}^\infty \sum_{r=0}^{n-1} |x_2(i_k,r)|^2$ is finite. But in this case $\lim_{k\to\infty} x_2(i_k, r) = 0$ for every r, while $\lim_{k\to\infty} x_1(i_k, r) = z(r)$. Accordingly $(z, 0) \in F'_{x_1x_2} = F'$. **Q**

(iii) Set $\beta = \sqrt{1-\alpha^2}$ and define $\tilde{T} : (\mathbb{R}^{I\times n})^2 \to \mathbb{R}^{I\times n}$ by setting $\tilde{T}(x_1, x_2) = \alpha x_1 + \beta x_2$ for x_1, $x_2 \in \mathbb{R}^{I\times n}$. Then $\tilde{T}$ is a continuous linear operator, so the image measure $\lambda\tilde{T}^{-1}$ is a centered Gaussian distribution on $\mathbb{R}^{I\times n}$ (456Ba). Moreover, it has the same covariance matrix as μ. **P** If i, $j \in I$ then

$$\begin{aligned}
\int x(i)x(j)(\lambda\tilde{T}^{-1})(dx) &= \int \tilde{T}(x_1,x_2)(i)\tilde{T}(x_1,x_2)(j)\lambda(d(x_1,x_2)) \\
&= \int (\alpha x_1(i) + \beta x_2(i))(\alpha x_1(j) + \beta x_2(j))\lambda(d(x_1,x_2)) \\
&= \alpha^2 \int x_1(i)x_1(j)\lambda(d(x_1,x_2)) + \beta^2 \int x_2(i)x_2(j)\lambda(d(x_1,x_2)) \\
&= (\alpha^2+\beta^2)\int x(i)x(j)\mu(dx) = \int x(i)x(j)\mu(dx). \ \textbf{Q}
\end{aligned}$$

So $\lambda\tilde{T}^{-1} = \mu$ (456Bb).

(iv) If x_1, $x_2 \in \mathbb{R}^I$ are such that $(z, 0) \in F'_{x_1x_2}$, then $\alpha z \in F_{\tilde{T}(x_1,x_2)}$. **P** For every $\epsilon > 0$ there is an $i \in I_\epsilon$ such that $|z(r) - x_1(i, r)| \leq \epsilon$ and $|x_2(i, r)| \leq \epsilon$ for every $r < n$. But now $|\alpha z(r) - \tilde{T}(x_1, x_2)(r)| \leq 2\epsilon$ for every $r < n$. **Q** So

$$\tilde{T}^{-1}[\{x : \alpha z \in F_x\}] = \{(x_1,x_2) : \alpha z \in F_{\tilde{T}(x_1,x_2)}\} \supseteq \{(x_1,x_2) : (z,0) \in F'_{x_1x_2}\}$$

is λ-conegligible, and $\alpha z \in F_x$ for μ-almost every x, that is, $\alpha z \in F$, as claimed.

(c) Suppose now that F is bounded.

(i) For $L \subseteq I$, $\alpha \geq 0$ set

$$Q(L,\alpha) = \textstyle\bigcup_{i\in L, r<n} \{x : |x(i,r)| \geq \alpha\}.$$

By 456C, applied to the image of μ under the map $x \mapsto x\restriction L : \mathbb{R}^I \to \mathbb{R}^L$,

$$\mu Q(L, \tfrac{1}{2}\alpha) \geq 2\mu Q(L,\alpha)(1 - \mu Q(L,\alpha))^3$$

for every finite $L \subseteq I$ and every $\alpha \geq 0$.

Let $\beta > 0$ be such that $\delta = 2\beta(1-(n+1)\beta)^3 - \beta > 0$, and let $\alpha_0 > 0$ be such that $\alpha_0^2\beta \geq 1$ and $\|z\| < \frac{1}{2}\alpha_0$ for every $z \in F$, so that $\mu\{x : |x(i,r)| \geq \alpha_0\} \leq \beta$ whenever $i \in I_1$ and $r < n$, and $\mu Q(\{i\}, \alpha_0) \leq n\beta$ for every $i \in I_1$. Set $K = \{z : z \in \mathbb{R}^n, \frac{1}{2}\alpha_0 \leq \max_{r<n} |z(r)| \leq \alpha_0\}$, so that K is a compact set disjoint from F. For almost every x,

$$\emptyset = K \cap F = K \cap F_x \supseteq \textstyle\bigcap_{k\geq 1} K \cap \overline{\{S_ix : i \in I_{1/k}\}},$$

so there is a $k \geq 1$ such that $S_ix \notin K$ for every $i \in I_{1/k}$. Since the sets

$$\{x : S_i(x) \in K \text{ for some } i \in I_{1/k}\}$$

form a non-increasing sequence of measurable sets with negligible intersection, there is a $k \geq 1$ such that

$$\mu\{x : S_i(x) \in K \text{ for some } i \in I_{1/k}\} < \delta.$$

(ii) ? Suppose, if possible, that

$$\mu Q(I_{1/k}, \alpha_0) > \beta.$$

Let $L \subseteq I_{1/k}$ be a finite set of minimal size such that $\gamma = \mu Q(L, \alpha_0) \geq \beta$. Since $\mu Q(\{i\}, \alpha_0) \leq n\beta$ for any $i \in L$, and L is minimal, we must have

$$\beta \leq \gamma \leq (n+1)\beta.$$

Now this means that

$$\mu Q(L, \tfrac{1}{2}\alpha_0) \geq 2\gamma(1-\gamma)^3$$

(see (i) above)

$$\geq 2\gamma(1-(n+1)\beta)^3 = \gamma(1+\frac{\delta}{\beta}) \geq \gamma + \delta,$$

so that $\mu(Q(L, \frac{1}{2}\alpha_0) \setminus Q(L, \alpha_0)) \geq \delta$. But if $x \in Q(L, \frac{1}{2}\alpha_0) \setminus Q(L, \alpha_0)$ there is some $i \in L$ such that $\max_{r<n} |x(i,r)| \geq \frac{1}{2}\alpha_0$ while $\max_{r<n} |x(i,r)| < \alpha_0$, in which case $S_i(x) \in K$. So we get

$$\delta \leq \mu(Q(L, \tfrac{1}{2}\alpha_0) \setminus Q(L, \alpha_0)) \leq \mu(\{x : S_i(x) \in K \text{ for some } i \in L\}$$
$$\leq \mu(\{x : S_i(x) \in K \text{ for some } i \in I_{1/k}\} < \delta$$

which is absurd. **X**

(iii) Thus $\mu Q(I_{1/k}, \alpha_0) \leq \beta$. For $\alpha \geq 0$, set $f(\alpha) = \mu Q(I_{1/k}, \alpha)$; then f is non-increasing. Also $f(\frac{1}{2}\alpha) \geq 2f(\alpha)(1-f(\alpha))^3$ for every α. **P?** Otherwise, because

$$f(\alpha) = \sup\{\mu Q(L, \alpha) : L \subseteq I_{1/k} \text{ is finite}\},$$

there is a finite $L \subseteq I_{1/k}$ such that $f(\frac{1}{2}\alpha) < 2\gamma(1-\gamma)^3$, where $\gamma = \mu Q(L, \alpha)$. But in this case $\mu Q(L, \frac{1}{2}\alpha) \leq f(\frac{1}{2}\alpha) < 2\gamma(1-\gamma)^3$, which is impossible, as remarked in (i). **XQ**

Set $\zeta = \lim_{\alpha\to\infty} f(\alpha)$. Then

$$\zeta = \lim_{\alpha\to\infty} f(\tfrac{1}{2}\alpha) \geq 2\zeta(1-\zeta)^3.$$

But we also know, from (ii), that $\zeta \leq f(\alpha_0) \leq \beta$. So $(1-\zeta)^3 \geq (1-\beta)^3 > \frac{1}{2}$ and ζ must be 0.

What this means is that if we set $\epsilon = \frac{1}{k}$ then

$$\lim_{\alpha\to\infty} \mu\{x : \sup_{i\in I_\epsilon, r<n} |x(i,r)| > \alpha\} = 0,$$

that is, $\sup_{i\in I_\epsilon, r<n} |x(i,r)|$ is finite for almost every $x \in \mathbb{R}^{I\times n}$, as claimed.

456J Lemma Let J be a set and μ a centered Gaussian distribution on $\mathbb{R}^J$. Let M be the linear subspace of $L^2(\mu)$ generated by $\{\pi_j^\bullet : j \in J\}$, where $\pi_j(x) = x(j)$ for $x \in \mathbb{R}^J$ and $j \in J$. If M is separable (for the norm topology) then μ is τ-additive.

proof Suppose, if possible, otherwise.

(a) There is an upwards-directed family $\mathcal{G}$ of open Baire sets in $\mathbb{R}^J$ such that $W_0 = \bigcup \mathcal{G}$ is a Baire set and $\mu W_0 > \sup_{G\in\mathcal{G}} \mu G$. Let $\mathcal{G}_0 \subseteq \mathcal{G}$ be a countable upwards-directed set such that $\sup_{G\in\mathcal{G}_0} \mu G = \sup_{G\in\mathcal{G}} \mu G$, and set $W_1 = W_0 \setminus \bigcup \mathcal{G}_0$; then $\mu W_1 > 0$ and $\mu(W_1 \cap G) = 0$ for every $G \in \mathcal{G}$. Let W be a non-negligible zero set included in W_1.

For each $n \in \mathbb{N}$, let $\mathcal{V}_n$ be a countable base for the topology of $\mathbb{R}^n$ consisting of open balls. Let $\mathcal{G}_n^*$ be the family of open sets of $\mathbb{R}^J$ of the form $T^{-1}[V]$, where $T : \mathbb{R}^J \to \mathbb{R}^n$ is a continuous linear operator, $V \subseteq \mathbb{R}^n$ is open and $\mu(W \cap T^{-1}[V]) = 0$. Of course $\mathcal{G}_0^* = \emptyset$.

(b) For $n \geq 1$ and $V \in \mathcal{V}_n$, let $\mathcal{T}_{nV}$ be the family of continuous linear operators $T : \mathbb{R}^J \to \mathbb{R}^n$ such that $W \cap T^{-1}[V]$ is negligible, but not included in $\bigcup \mathcal{G}^*_{n-1}$. Index $\mathcal{T}_{nv}$ as $\langle T_i \rangle_{i \in I(n,V)}$; it will be convenient to do this in such a way that all the $I(n,V)$ are disjoint. Define f_{ir}, for $i \in I(n,V)$ and $r < n$, by saying that $T_i(x) = \langle f_{ir}(x) \rangle_{r<n}$ for $x \in \mathbb{R}^J$. Define $\phi_n : \bigcup_{V \in \mathcal{V}_n} I(n,V) \to M^n$ by setting $\phi_n(i) = \langle f^\bullet_{ir} \rangle_{r<n}$ for each $i \in \bigcup_{V \in \mathcal{V}_n} I(n,V)$. Because M is separable in its norm topology, M^n is separable in its product topology (4A2Pa). Fix a countable set $I'(n,V) \subseteq I(n,V)$ such that $\{\phi_n(i) : i \in I'(n,V)\}$ is dense in $\{\phi_n(i) : i \in I(n,V)\}$. Set $\rho_n(\langle u_r \rangle_{r<n}, \langle v_r \rangle_{r<n}) = \max_{r<n} \|u_r - v_r\|_2$ for $\langle u_r \rangle_{r<n}$, $\langle v_r \rangle_{r<n} \in M^n$, so that ρ_n is a metric defining the product topology of M^n.

(c) If $j \in I(n,V)$, then there is a $\delta > 0$ such that

$$\{T_i(x) : i \in I'(n,V),\ \rho_n(\phi_n(i), \phi_n(j)) \leq \delta\}$$

is bounded for almost every $x \in \mathbb{R}^J$. **P** For $i \in I'(n,V)$ and $r < n$, set $f'_{ir} = f_{ir} - f_{jr}$, $T'_i = T_i - T_j$; for $\delta > 0$, write I'_δ for

$$\{i : i \in I'(n,V),\ \rho_n(\phi_n(i), \phi_n(j)) \leq \delta\} = \{i : i \in I'(n,V),\ \|f'_{ir}\|_2 \leq \delta \text{ for every } r < n\}.$$

Because $\phi_n(j) \in \overline{\{\phi_n(i) : i \in I'(n,V)\}}$, no I'_δ is empty. So 456Ia tells us that there is a closed set $F \subseteq \mathbb{R}^n$ such that

$$F = F_x = \bigcap_{\delta > 0} \overline{\{T'_i(x) : i \in I'_\delta\}}$$

for almost every $x \in \mathbb{R}^J$. By 456Ib, $\alpha z \in F$ whenever $z \in F$ and $|\alpha| \leq 1$. **?** If F is not bounded, then it must include a line L through 0. (The sets $\{\frac{1}{n} z : z \in F, \|z\| = n\}$, for $n \geq 1$, form a non-increasing sequence of non-empty compact sets, so there is a point z_0 belonging to them all; take L to be the set of multiples of z_0.) Let $D \subseteq L$ be a countable dense set. For $z \in D$ and $k \in \mathbb{N}$ we know that

for every $i \in I(n,V)$, $T_i(x) \notin V$ for almost every $x \in W$,

for almost every $x \in \mathbb{R}^J$ there is an $i \in I'(n,V)$ such that $\|T_i(x) - T_j(x) - z\| \leq 2^{-k}$

and therefore

for almost every $x \in W$, $T_i(x) \notin V$ for every $i \in I'(n,V)$, but there is an $i \in I'(n,V)$ such that $\|T_i(x) - T_j(x) - z\| \leq 2^{-k}$

so that

for almost every $x \in W$, the distance from $T_j(x) + z$ to the closed set $\mathbb{R}^n \setminus V$ is at most 2^{-k}.

This is true for every $k \in \mathbb{N}$, so we get

$T_j(x) + z \notin V$ for almost every $x \in W$.

And *this* is true for every $z \in D$, so we get

for almost every $x \in W$, $T_j(x) + z \notin V$ for every $z \in D$, so $T_j(x) \notin V + L$.

Let $S : \mathbb{R}^n \to \mathbb{R}^{n-1}$ be a linear operator with kernel L, and set $V' = S[V]$. Then $V' \subseteq \mathbb{R}^{n-1}$ is open, and $W \cap (ST_j)^{-1}[V'] = W \cap T_j^{-1}[V + L]$ is negligible. But this means that $T_j^{-1}[V] \subseteq (ST_j)^{-1}[V'] \in \mathcal{G}^*_{n-1}$ and $T_j^{-1}[V]$ is included in $\bigcup \mathcal{G}^*_{n-1}$; which contradicts the definition of $\mathcal{T}_{nV}$. **X**

So F is bounded. By 456Ic, there is some $\delta > 0$ such that $\sup_{i \in I'_\delta, r<n} |f'_{ir}(x)| < \infty$ for almost every $x \in \mathbb{R}^J$. Of course this means that $\{T_i(x) : i \in I(n,V), \rho_n(\phi_n(i), \phi_n(j)) \leq \delta\}$ is bounded for almost every $x \in \mathbb{R}^J$. **Q**

(d) Accordingly $\phi_n[I(n,V)]$ is covered by the family $\mathcal{U}_{nV}$ of open sets $U \subseteq M^n$ such that $\{T_i(x) : i \in I'(n,V),\ \phi_n(i) \in U\}$ is bounded for almost every x. Because M^n is separable and metrizable, it is hereditarily Lindelöf (4A2P(a-iii)), so there is a sequence $\langle U_{nVk} \rangle_{k \in \mathbb{N}}$ in $\mathcal{U}_{nV}$ covering $\phi_n[I(n,V)]$. For each k, set $I_{nVk} = I'(n,V) \cap \phi_n^{-1}[U_{nVk}]$. Then $\{T_i(x) : i \in I_{nVk}\}$ is bounded for almost every x. Because $\phi_n[I'(n,V)]$ is dense in $\phi_n[I(n,V)]$, $\phi_n[I_{nVk}] = \phi_n[I'(n,V)] \cap U_{nVk}$ is dense in $\phi_n[I(n,V)] \cap U_{nVk}$. So for every $i \in I(n,V)$ there is a $k \in \mathbb{N}$ such that $\phi_n(i) \in \overline{\phi_n[I_{nVk}]}$.

(e) Recall that $W \subseteq \mathbb{R}^J$ is a non-negligible zero set included in

$$\bigcup_{n \geq 1} \bigcup \mathcal{G}^*_n = \bigcup_{n \geq 1} \bigcup_{V \in \mathcal{V}_n} \bigcup_{i \in I(n,V)} T_i^{-1}[V].$$

Let $J_0 \subseteq J$ be a countable set such that W is determined by coordinates in J_0.

Let $\langle \epsilon_j \rangle_{j\in J_0}$ and $\langle \epsilon'_{nVk} \rangle_{n\geq 1, V\in\mathcal{V}_n, k\in\mathbb{N}}$ be families of strictly positive real numbers such that $\sum_{j\in J_0} \epsilon_j$ and $\sum_{n=1}^\infty \sum_{V\in\mathcal{V}_n} \sum_{k=0}^\infty \epsilon'_{nVk}$ are both at most $\frac{1}{3}\mu W$. Let $\langle \gamma_j \rangle_{j\in J_0}$ and $\langle \gamma'_{nVk} \rangle_{n\geq 1, V\in\mathcal{V}_n, k\in\mathbb{N}}$ be such that

$$\mu\{x : x \in \mathbb{R}^J, |x(j)| \geq \gamma_j\} \leq \epsilon_j \text{ for every } j \in J_0,$$

$$\mu\{x : x \in \mathbb{R}^J, \sup_{i\in I_{nVk}} \|T_i(x)\| \geq \gamma'_{nVk}\} \leq \epsilon'_{nVk} \text{ for every } n \geq 1,\ V \in \mathcal{V}_n,\ k \in \mathbb{N}.$$

Set $W' = \{x : x \in W, |x(j)| \leq \gamma_j \text{ for every } j \in J_0\}$; then $\mu W' \geq \frac{2}{3}\mu W$ and W' is of the form $C \times \mathbb{R}^{J\setminus J_0}$, where $C \subseteq \mathbb{R}^{J_0}$ is compact. Set

$$W'' = \{x : x \in W', \|T_i(x)\| \leq \gamma'_{nVk} \text{ whenever } n \geq 1,\ V \in \mathcal{V}_n,\ k \in \mathbb{N} \text{ and } i \in I_{nVk}\};$$

then $\mu W'' \geq \frac{1}{3}\mu W$.

(f) Set $I = \bigcup_{n\geq 1, V\in\mathcal{V}_n} I(n,V) \times n$. If $K \subseteq I$ is finite, then

$$W'_K = \{x : x \in W', \|f_{ir}(x)\| \leq \gamma'_{nVk} \text{ whenever } n \geq 1,\ V \in \mathcal{V}_n,\ k \in \mathbb{N},\ (i,r) \in K \text{ and } \phi_n(i) \in K \cap \overline{\phi_n[I_{nVk}]}\}$$

has measure at least $\frac{1}{3}\mu W$. **P** For each quintuple (i,r,n,V,k) with $n \geq 1$, $V \in \mathcal{V}_n$, $k \in \mathbb{N}$, $(i,r) \in K$ and $\phi_n(i) \in \overline{\phi_n[I_{nVk}]}$, there is a sequence $\langle i_m \rangle_{m\in\mathbb{N}}$ in I_{nVk} such that $\rho_n(\phi_n(i), \phi_n(i_m)) \leq 2^{-m}$ for every m; so that $\|f_{ir} - f_{i_m r}\|_2 \leq 2^{-m}$ for every m. But this means that $f_{ir}(x) = \lim_{m\to\infty} f_{i_m r}(x)$ for almost every $x \in \mathbb{R}^J$. Accordingly $|f_{ir}(x)| \leq \gamma'_{nVk}$ for almost every $x \in W''$. Since there are only countably many such quintuples (i,r,n,V,k), we see that $W'' \setminus W'_K$ is negligible, so $\mu W'_K \geq \mu W'' \geq \frac{1}{3}\mu W$. **Q**

(g) For $x \in \mathbb{R}^J$, define $Tx \in \mathbb{R}^I$ by setting $(Tx)(i,r) = f_{ir}(x)$ for $i \in I(n,V)$ and $r < n$. Then $T : \mathbb{R}^J \to \mathbb{R}^I$ is a continuous linear operator. By 4A4H, $T[W']$ is closed.

For finite $K \subseteq I$, let $\mathcal{H}_K$ be the family of open subsets H of $\mathbb{R}^K$ such that $\mu\{x : x \in W, Tx\restriction K \in H\} = 0$. Then $\mathcal{H}_K$ is closed under countable unions so has a largest member H_K. Now there is a $K \in [I]^{<\omega}$ such that $Tx\restriction K \in H_K$ for every $x \in W'_K$. **P?** Otherwise, choose for each $K \in [I]^{<\omega}$ an $x_K \in W'_K$ such that $Tx_K\restriction K \notin H_K$. Let $\mathcal{F}$ be an ultrafilter on $[I]^{<\omega}$ containing $\{K : L \subseteq K \in [I]^{<\omega}\}$ for every finite $L \subseteq I$. If $(i,r) \in I$, there are $n \geq 1$, $V \in \mathcal{V}_n$ and $k \in \mathbb{N}$ such that $r < n$ and $\phi_n(i) \in \overline{\phi_n[I_{nVk}]}$, in which case $|f_{ir}(x_K)| \leq \gamma'_{nVk}$ whenever $(i,r) \in K \in [I]^{<\omega}$. This means that $\lim_{K\to\mathcal{F}} f_{ir}(x_K)$ must be defined in $[-\gamma'_{nVk}, \gamma'_{nVk}]$; consequently $y^* = \lim_{K\to\mathcal{F}} Tx_K$ is defined in $\mathbb{R}^I$. Since $x_K \in W'$ for every K, $y^* \in \overline{T[W']} = T[W']$.

Let $x^* \in W'$ be such that $Tx^* = y^*$. Since $x^* \in W$, there are $n \geq 1$, $V \in \mathcal{V}_n$ and $i \in I(n,V)$ such that $T_i(x^*) \in V$. Set $L = \{(i,r) : r < n\}$, $H = \{z : z \in \mathbb{R}^L, \langle z(i,r)\rangle_{r<n} \in V\}$; then $\{x : Tx\restriction L \in H\} = T_i^{-1}[V]$. Since $y^*\restriction L = Tx^*\restriction L$ belongs to H, and H is open, there must be a $K \supseteq L$ such that $Tx_K\restriction L \in H$. But in this case $H' = \{z : z \in \mathbb{R}^K, z\restriction L \in H\}$ is an open subset of $\mathbb{R}^K$ and

$$\{x : Tx\restriction K \in H'\} = \{x : Tx\restriction L \in H\} = \{x : T_i(x) \in V\}$$

meets W in a negligible set, and $H' \subseteq H_K$. But this means that $Tx_K\restriction K \in H_K$, contrary to the choice of x_K. **XQ**

(h) Putting (f) and (g) together, we find ourselves trying to believe simultaneously that $\mu W'_K > 0$ and that $Tx\restriction K \in H_K$ for every $x \in W'_K$ and that $W'_K \subseteq W$ and that $\{x : x \in W, Tx\restriction K \in H_K\}$ is negligible. Faced with this we have to abandon the original supposition that μ is not τ-additive.

456K We now have all the ideas needed for the main theorem of this section.

Theorem (Talagrand 81) Every centered Gaussian distribution is τ-additive.

proof ? Suppose, if possible, that μ is a centered Gaussian distribution on a set $\mathbb{R}^I$ which is not τ-additive.

(a) By 456G, there are a set J and a universal centered Gaussian distribution ν on $\mathbb{R}^J$ and a continuous linear operator $T : \mathbb{R}^J \to \mathbb{R}^I$ which is inverse-measure-preserving for ν and μ. By 418Ha, ν is not τ-additive.

(b) As in part (a) of the proof of 456J, there are a non-negligible zero set $W \subseteq \mathbb{R}^J$ and a family $\mathcal{G}$ of open sets, covering W, such that $\nu(W \cap G) = \emptyset$ for every $G \in \mathcal{G}$. Give J a Hilbert space structure such

that $\int x(i)x(j)\nu(dx) = (i|j)$ for all $i, j \in J$. Let $K_0 \subseteq J$ be a countable set such that W is determined by coordinates in K_0, and let K be the closed linear subspace of J generated by K_0. Let $\mathcal{G}'$ be the family of open sets determined by coordinates in K which meet W in negligible sets. Then $W \subseteq \bigcup \mathcal{G}'$, by 456H.

Let λ be the centered Gaussian distribution on $\mathbb{R}^K$ for which the map $\tilde{\pi}_K = x \mapsto x\restriction K : \mathbb{R}^J \to \mathbb{R}^K$ is inverse-measure-preserving. Then $\tilde{\pi}_K[W]$ is a zero set in $\mathbb{R}^K$, $\lambda\tilde{\pi}_K[W] = \nu W > 0$, $\{\tilde{\pi}_K[G] : G \in \mathcal{G}'\}$ is a family of open sets in $\mathbb{R}^K$ covering $\tilde{\pi}_K[W]$, and $\lambda(\tilde{\pi}_K[W] \cap \tilde{\pi}_K[G]) = \nu(W \cap G) = 0$ for every $G \in \mathcal{G}'$; so λ is not τ-additive. However, K, regarded as a normed space, is separable (see 4A4Bi); and if we set $\pi_j(y) = y(j)$ for $y \in \mathbb{R}^K$ and $j \in K$, then $\|\pi_i^\bullet - \pi_j^\bullet\|_2 = \|i - j\|$ for all $i, j \in K$. So $\{\pi_j^\bullet : j \in K\}$ is separable in $L^2(\lambda)$. And this is impossible, by 456J. **X**

Thus every centered Gaussian distribution must be τ-additive.

456L Corollary If μ is a centered Gaussian distribution on $\mathbb{R}^I$, there is a unique quasi-Radon measure $\tilde{\mu}$ on $\mathbb{R}^I$ extending μ. The support of μ as defined in 456D is the support of $\tilde{\mu}$ as defined in 411N.

proof By 415L, μ has a unique extension to a quasi-Radon measure $\tilde{\mu}$. Now the support Z of μ is a closed set, so $\tilde{\mu}Z = \mu^*Z$ (415L(i)). Also Z is self-supporting for μ. If $G \subseteq \mathbb{R}^I$ is an open set meeting Z, then there is a cozero set $H \subseteq G$ which also meets Z, and $\mu^*(Z \cap H) > 0$. It follows that $\mu^*(Z \setminus H) < 1$; as $\tilde{\mu}$ extends μ, $\tilde{\mu}(Z \setminus H) < 1$ and $\tilde{\mu}(Z \cap G) > 0$. This shows that Z is self-supporting for $\tilde{\mu}$, so must be the support of $\tilde{\mu}$ in the standard sense.

456M Gaussian processes I take half a page to spell out the connexion between centered Gaussian distributions, as defined in 456A, and the corresponding processes considered in 454J-454K.

Proposition Let $\langle X_i\rangle_{i\in I}$ be a family of random variables on a probability space (Ω, Σ, μ). Then the following are equiveridical:

(i) the distribution of $\langle X_i\rangle_{i\in I}$, in the sense of 454K, is a centered Gaussian distribution;

(ii) whenever $i_0, \dots, i_n \in I$ and $\alpha_0, \dots, \alpha_n \in \mathbb{R}$ then $\sum_{r=0}^n \alpha_r X_{i_r}$ is either zero a.e. or a normal random variable with zero expectation;

(iii) whenever $i_0, \dots, i_n \in I$ then the joint distribution of $X_{i_0}, \dots, X_{i_n}$, in the sense of 271C, is a centered Gaussian distribution;

(iv) whenever $J \subseteq I$ is finite then there is an independent family $\langle Y_k\rangle_{k\in K}$ of standard normal random variables on Ω such that each X_i, for $i \in J$, is almost everywhere equal to a linear combination of the Y_k.

proof (ii) $\iff$ (i) is immediate from the definition in 456Ab and 454L.

(i) $\iff$ (iii) is also direct from 456Ab and the identification of the two concepts of 'distribution' (454K).

(iv)$\Rightarrow$(ii) is direct from 274A-274B.

(i)$\Rightarrow$(iv) For $i \in J$ set $u_i = X_i^\bullet$ in $L^2(\mu)$. By 4A4Jg there is an orthonormal family $\langle v_k\rangle_{k\in K}$ in $L^2(\mu)$ such that each v_k is a linear combination of the u_i and each u_i is a linear combination of the v_k. Take Y_k such that $Y_k^\bullet = v_k$ for each k; then each X_i is equal almost everywhere to a linear combination of the Y_k, while each Y_k is equal almost everywhere to a linear combination of the X_i. As $\#(K)$ must be the dimension of the linear span of $\{u_i : i \in J\}$, K is finite. Any linear combination of the Y_k is equal almost everywhere to a linear combination of the X_k, so is either zero a.e. or a normal random variable with zero expectation. Because (ii)$\Rightarrow$(iii), $\langle Y_k\rangle_{k\in K}$ has a centered Gaussian distribution ν say. Each Y_k has variance $(v_k|v_k) = 1$, so is a standard normal random variable.

The covariance matrix of ν is given by

$$\int y(j)y(k)\nu(dy) = \mathbb{E}(Y_j \times Y_k) = (v_j|v_k) = 1 \text{ if } j = k$$
$$= 0 \text{ otherwise.}$$

But this means that ν has the same covariance matrix as the product measure $\mu_G^{(K)}$, which is also a centered Gaussian distribution (456Bc). So $\nu = \mu_G^{(K)}$ (456Bb). But this means that $\langle Y_k\rangle_{k\in K}$ is independent (272G). Thus we have found a suitable family.

456N Definition A family of random variables satisfying the equivalent conditions in 456M is a **centered Gaussian process**.

456X Basic exercises >(a) Let I be a set and $\langle\sigma_{ij}\rangle_{i,j\in I}$ a family of real numbers. Show that the following are equiveridical: (i) $\langle\sigma_{ij}\rangle_{i,j\in I}$ is the covariance matrix of a centered Gaussian distribution on $\mathbb{R}^I$; (ii) there are a Hilbert space U and a family $\langle u_i\rangle_{i\in I}$ in U such that $(u_i|u_j)=\sigma_{ij}$ for all i, $j\in I$; (iii) $\langle\sigma_{ij}\rangle_{i,j\in J}$ is the covariance matrix of a centered Gaussian distribution on $\mathbb{R}^J$ for every finite $J\subseteq I$; (iv) $\sigma_{ij}=\sigma_{ji}$ for all i, $j\in I$ and $\sum_{i,j\in J}\alpha_i\alpha_j\sigma_{ij}\geq 0$ whenever $J\subseteq I$ is finite and $\langle\alpha_i\rangle_{i\in J}\in\mathbb{R}^J$. (*Hint*: 4A4Jg, for finite I, and 454G. For (iv)⇒(iii) use the finite-dimensional version of 4A4M.)

(b) Let $n\geq 1$ be an integer. (i) Show that $\mu_G^{(n)}T^{-1}=\mu_G^{(n)}$ for any orthogonal linear operator $T:\mathbb{R}^n\to\mathbb{R}^n$. (ii) Set $p(x)=\frac{1}{\|x\|}x$ for $x\in\mathbb{R}^n\setminus\{0\}$; take $p(0)$ to be any point of S^{n-1}. Show that $\mu_G^{(n)}p^{-1}$ is a multiple of $(n-1)$-dimensional Hausdorff measure on S^{n-1}. (*Hint*: 443T.)

(c) Let I be a countable set, μ a centered Gaussian distribution on $\mathbb{R}^I$, and $\gamma\geq 0$. Set $\alpha=\mu\{x:\sup_{i\in I}|x(i)|\geq\gamma)$. Show that $\mu\{x:\sup_{i\in I}|x(i)|\geq\frac{1}{2}\gamma)\geq 2\alpha(1-\alpha)^3$.

(d) (i) Let U and V be Hilbert spaces, $I\subseteq U$ a set and $f:I\to V$ a function such that $(f(u)|f(v))=(u|v)$ for all u, $v\in I$. Show that there is a linear operator $T:U\to V$, extending f, such that $(Tu|Tv)=(u|v)$ for all u, $v\in U$. (ii) Let I be a set and $\langle\sigma_{ij}\rangle_{i,j\in I}$ a family of real numbers. Show that there is at most one inner product space structure on I for which $\sigma_{ij}=(i|j)$ for all i, $j\in I$.

(e) Let $\langle X_n\rangle_{n\in\mathbb{N}}$ be an independent sequence of standard normal random variables. Show that for any square-summable sequence $\langle\alpha_n\rangle_{n\in\mathbb{N}}$ and any bijection $\pi:\mathbb{N}\to\mathbb{N}$, $\sum_{n=0}^\infty\alpha_nX_n$ and $\sum_{n=0}^\infty\alpha_{\pi(n)}X_{\pi(n)}$ are finite and equal a.e. (*Hint*: 273B.)

>(f) For any set I, I will say that a **centered Gaussian quasi-Radon measure** on $\mathbb{R}^I$ is a quasi-Radon measure μ on $\mathbb{R}^I$ such that every continuous linear functional $f:\mathbb{R}^I\to\mathbb{R}$ is either zero a.e. or is normally distributed with zero expectation. Show that

(i) there is a one-to-one correspondence between centered Gaussian quasi-Radon measures μ on $\mathbb{R}^I$ and centered Gaussian distributions ν on $\mathbb{R}^I$ obtained by matching μ with ν iff they agree on the zero sets of $\mathbb{R}^I$;

(ii) if μ, ν are centered Gaussian quasi-Radon measures on $\mathbb{R}^I$ and $\int x(i)x(j)\mu(dx)=\int x(i)x(j)\nu(dx)$ for all i, $j\in I$, then $\mu=\nu$;

(iii) the support of a centered Gaussian quasi-Radon measure on $\mathbb{R}^I$ is a linear subspace of $\mathbb{R}^I$;

(iv) if $\langle I_j\rangle_{j\in J}$ is a disjoint family of sets with union I, and μ_j is a centered Gaussian quasi-Radon measure on $\mathbb{R}^{I_j}$ for each $j\in J$, then the quasi-Radon product of $\langle\mu_j\rangle_{j\in J}$, regarded as a measure on $\mathbb{R}^I$, is a centered Gaussian quasi-Radon measure.

>(g) Show that the completion of the measure on $\Omega=\mathbb{R}^{[0,\infty[}$ described in 455C is a centered Gaussian distribution with covariance matrix $\sigma=\langle\min(s,t)\rangle_{s,t\in[0,\infty[}$.

>(h) Let $\langle X_i\rangle_{i\in I}$ be a Gaussian process. Show that $\langle X_i\rangle_{i\in I}$ is independent iff $\mathbb{E}(X_i\times X_j)=0$ for all distinct i, $j\in I$.

456Y Further exercises (a) Let (Ω,Σ,μ) be a probability space with measure algebra $(\mathfrak{A},\bar\mu)$, and $\langle u_i\rangle_{i\in I}$ a family in $L^2(\mu)\cong L^2(\mathfrak{A},\bar\mu)$ which is a Gaussian process in the sense that whenever $X_i\in\mathcal{L}^2(\mu)$ is such that $X_i^\bullet=u_i$ for every i, then $\langle X_i\rangle_{i\in I}$ is a Gaussian process. Suppose that $\gamma\geq 0$ and that $\alpha=\bar\mu(\sup_{i\in I}[\![|u_i|\geq\gamma]\!])$. Show that $\bar\mu(\sup_{i\in I}[\![|u_i|\geq\frac{1}{2}\gamma]\!])\geq 2\alpha(1-\alpha)^3$.

(b) Let U be a Hilbert space with an orthonormal basis $\langle u_j\rangle_{j\in J}$, and μ the universal centered Gaussian distribution on $\mathbb{R}^U$ with covariance matrix defined by the inner product of U. Show that there is a function $T:\mathbb{R}^J\to\mathbb{R}^U$, inverse-measure-preserving for $\mu_G^{(J)}$ and μ, such that whenever $\langle j_n\rangle_{n\in\mathbb{N}}$ is a sequence of distinct elements of J and $\langle\alpha_n\rangle_{n\in\mathbb{N}}$ is a square-summable sequence in $\mathbb{R}$, then $(Tx)(\sum_{n=0}^\infty\alpha_nu_{j_n})=\sum_{n=0}^\infty\alpha_nx(j_n)$ for almost every $x\in\mathbb{R}^J$.

(c) Let U be an infinite-dimensional Hilbert space and μ the universal centered Gaussian distribution on $\mathbb{R}^U$ with covariance matrix defined by the inner product of U. Show that $\mu C = 0$ for every compact set $C \subseteq \mathbb{R}^U$. (*Hint*: there is an $m \in \mathbb{N}$ such that $\{u : |x(u)| \leq m \text{ for every } x \in C\}$ is somewhere dense in U.)

(d) Let μ be a centered Gaussian distribution on a set $\mathbb{R}^I$. Show that the following are equiveridical: (i) μ has countable Maharam type; (ii) $L^2(\mu)$ is separable; (iii) I is separable under the pseudometric $(i,j) \mapsto \sqrt{\int (x(i)-x(j))^2 \mu(dx)}$.

(e) Fix $p \in \left]-\frac{1}{2}, \frac{1}{2}\right[\setminus \{0\}$. (i) For $\alpha \in \mathbb{R}$ set $f_\alpha(t) = |t-\alpha|^p - |t|^p$ when this is defined. Show that $f_\alpha \in L^2(\mu_L)$, where μ_L is Lebesgue measure, that $\|f_\alpha\|_2^2 = |\alpha|^{2p+1}\|f_1\|_2^2$ and that $\|f_\alpha - f_\beta\|_2 = \|f_{\alpha-\beta}\|_2$ for all α, $\beta \in \mathbb{R}$. (ii) Show that there is a centered Gaussian process $\langle X_\alpha \rangle_{\alpha \in \mathbb{R}}$ such that $\mathbb{E}(X_\alpha \times X_\beta) = |\alpha|^{2p+1} + |\beta|^{2p+1} - |\alpha-\beta|^{2p+1}$ for all α, $\beta \in \mathbb{R}$. (iii) Show that such a process can be represented by a Radon measure on $C(\mathbb{R})$. (*Hint*: 455Yc.) (This is **fractional Brownian motion**.)

456 Notes and comments This section has taken a direct route to Talagrand's theorem 456K, leaving all the real reasons for studying Gaussian processes (see FERNIQUE 97) to one side. I hope that it will nevertheless be clear from such fragments as 252Xh, 456Bb, 456C and the exercises here that they are one of the many concepts of probability theory which are both important and delightful.

457 Simultaneous extension of measures

The questions addressed in §§451, 454 and 455 can all be regarded as special cases of a general class of problems: given a set X and a family $\langle \nu_i \rangle_{i \in I}$ of (probability) measures on X, when can we expect to find a measure on X extending every ν_i? An alternative formulation, superficially more general, is to ask: given a set X, a family $\langle (Y_i, \mathrm{T}_i, \nu_i) \rangle_{i \in I}$ of probability spaces, and functions $\phi_i : X \to Y_i$ for each i, when can we find a measure on X for which every ϕ_i is inverse-measure-preserving? Even the simplest non-trivial case, when $X = \prod_{i \in I} Y_i$ and every ϕ_i is the coordinate map, demands a significant construction (the product measures of Chapter 25). In this section I bring together a handful of important further cases which are accessible to the methods of this chapter. I begin with a discussion of extensions of finitely additive measures (457A-457D), which are much easier, before considering the problems associated with countably additive measures (457E-457H).

457A It is helpful to start with a widely applicable result on common extensions of *finitely* additive measures.

Lemma Let $\mathfrak{A}$ be a Boolean algebra and $\langle \mathfrak{B}_i \rangle_{i \in I}$ a non-empty family of subalgebras of $\mathfrak{A}$. For each $i \in I$, we may identify $L^\infty(\mathfrak{B}_i)$ with the closed linear subspace of $L^\infty(\mathfrak{A})$ generated by $\{\chi b : b \in \mathfrak{B}_i\}$ (363Ga). Suppose that for each $i \in I$ we are given a finitely additive functional $\nu_i : \mathfrak{B}_i \to [0,1]$ such that $\nu_i 1 = 1$. Write $\int \dots d\nu_i$ for the corresponding positive linear functional on $L^\infty(\mathfrak{B}_i)$ (363L). Then the following are equiveridical:

(i) there is an additive functional $\mu : \mathfrak{A} \to [0,1]$ extending every ν_i;

(ii) whenever $i_0, \dots, i_n \in I$, $a_k \in \mathfrak{B}_{i_k}$ for $k \leq n$, and $\sum_{k=0}^n \chi a_k \geq m\chi 1$ in $S(\mathfrak{A})$, where $m \in \mathbb{N}$, then $\sum_{k=0}^n \nu_{i_k} a_k \geq m$;

(iii) whenever $i_0, \dots, i_n \in I$, $a_k \in \mathfrak{B}_{i_k}$ for $k \leq n$, and $\sum_{k=0}^n \chi a_k \leq m\chi 1$, where $m \in \mathbb{N}$, then $\sum_{k=0}^n \nu_{i_k} a_k \leq m$;

(iv) whenever $i_0, \dots, i_n \in I$, $u_k \in L^\infty(\mathfrak{B}_{i_k})$ for every $k \leq n$, and $\sum_{k=0}^n u_k \geq \chi 1$, then $\sum_{i=0}^n \int u_k d\nu_{i_k} \geq 1$;

(v) whenever $i_0, \dots, i_n \in I$, $u_k \in L^\infty(\mathfrak{B}_{i_k})$ for every $k \leq n$, and $\sum_{k=0}^n u_k \leq \chi 1$, then $\sum_{i=0}^\infty \int u_k d\nu_{i_k} \leq 1$.

proof (a) It is elementary to check that if (i) is true then (ii)-(v) are all true, simply because we have a positive linear functional $\int d\mu$ extending all the functionals $\int d\nu_i$.

(b)(ii)⇒(iii) Given that $a_k \in \mathfrak{B}_{i_k}$ and $\sum_{k=0}^n \chi a_k \leq m\chi 1$, then

$$\sum_{k=0}^n \chi(1 \setminus a_k) = (n+1)\chi 1 - \sum_{k=0}^n \chi a_k \geq (n+1-m)\chi 1,$$

so

$$\sum_{k=0}^n \nu_{i_k} a_k = n+1-\sum_{k=0}^n \nu_{i_k}(1\setminus a_k) \le n+1-(n+1-m) = m,$$

as required by (iii).

(c)(iii)⇒(i) Assume (iii). Set $\psi a = \sup\{\nu_i a : i \in I,\ a \in \mathfrak{B}_i\}$ for $a \in \mathfrak{A}$ (interpreting $\sup\emptyset$ as 0, as usual in such contexts). Then (iii) tells us that ψ satisfies the condition (ii) of 391F. So there is a non-negative finitely additive functional μ such that $\mu 1 = 1$ and $\mu a \ge \psi a$ for every $a \in \mathfrak{A}$, that is, $\mu b \ge \nu_i b$ whenever $i \in I$ and $b \in \mathfrak{B}_i$. But observe now that, because $\mu 1 = \nu 1$ and $\mu(1\setminus b) \ge \nu_i(1\setminus b)$, we actually have $\mu b = \nu_i b$ for every $b \in \mathfrak{B}_i$, so that μ extends ν_i, for every $i \in I$.

(d)(iv)⇒(ii) & (v)⇒(iii) are elementary; if $m > 0$, apply (iv) or (v) to $u_k = \frac{1}{m}\chi a_k$.

457B Corollary Let X be a set and $\langle Y_i\rangle_{i\in I}$ a family of sets. Suppose that for each $i \in I$ we have an algebra $\mathcal{E}_i$ of subsets of Y_i, an additive functional $\nu_i : \mathcal{E}_i \to [0,1]$ such that $\nu_i Y_i = 1$, and a function $f_i : X \to Y_i$. Then the following are equiveridical:

(i) there is an additive functional $\mu : \mathcal{P}X \to [0,1]$ such that $\mu f_i^{-1}[E] = \nu_i E$ whenever $i \in I$ and $E \in \mathcal{E}_i$;

(ii) whenever $i_0,\dots,i_n \in I$ and $E_k \in \mathcal{E}_{i_k}$ for $k \le n$, then there is an $x \in X$ such that $\sum_{k=0}^n \nu_{i_k} E_k \le \#(\{k : k \le n,\ f_{i_k}(x) \in E_k\})$.

proof (i)⇒(ii) is elementary; if $m = \lceil \sum_{k=0}^n \nu_{i_k} E_k\rceil - 1$, then $\sum_{k=0}^n \mu f_{i_k}^{-1}[E_k] > m\mu X$, so $\sum_{k=0}^n \chi f_{i_k}^{-1} E_k \not\le m\chi X$, that is, there is an $x \in X$ such that

$$\#(\{k : f_{i_k}(x) \in E_k\}) = \sum_{k=0}^n (\chi f_{i_k}^{-1}[E_k])(x) \ge m+1 \ge \sum_{k=0}^n \nu_{i_k} E_k.$$

(ii)⇒(i) Now suppose that (ii) is true. For $i \in I$ set $\mathfrak{B}_i = \{f_i^{-1}[E] : E \in \mathcal{E}_i\}$. Note that if $E \in \mathcal{E}_i$ and $\nu_i E > 0$, then (applying (ii) with $n = 0$, $i_0 = i$ and $E_0 = E$) $f_i^{-1}[E]$ cannot be empty; accordingly we have an additive functional $\nu_i' : \mathfrak{B}_i \to [0,1]$ defined by setting $\nu_i' f^{-1}[E] = \nu_i E$ for every $E \in \mathcal{E}_i$, and $\nu_i' X = 1$. If $i_0,\dots,i_n \in I$, $H_0 \in \mathfrak{B}_{i_0},\dots,H_n \in \mathfrak{B}_{i_n}$ and $m \in \mathbb{N}$ are such that $\sum_{k=0}^n \chi H_k \le m\chi X$, express each H_k as $f_{i_k}^{-1}[E_k]$, where $E_k \in \mathcal{E}_{i_k}$; then there is an $x \in X$ such that

$$\sum_{k=0}^n \nu_{i_k}' H_k = \sum_{k=0}^n \nu_{i_k} E_k \le \#(\{k : f_k(x) \in E_k\}) = \sum_{k=0}^m \chi H_k(x) \le m.$$

But this means that the condition of 457A(iii) is satisfied, with $\mathfrak{A} = \mathcal{P}X$, so 457A(i) and (i) here are also true.

457C Corollary (a) Let $\mathfrak{A}$ be a Boolean algebra and $\mathfrak{B}_1$, $\mathfrak{B}_2$ two subalgebras of $\mathfrak{A}$ with finitely additive functionals $\nu_i : \mathfrak{B}_i \to [0,1]$ such that $\nu_1 1 = \nu_2 1 = 1$. Then the following are equiveridical:

(i) there is an additive functional $\mu : \mathfrak{A} \to [0,1]$ extending both the ν_i;

(ii) whenever $b_1 \in \mathfrak{B}_1$, $b_2 \in \mathfrak{B}_2$ and $b_1 \cup b_2 = 1$, then $\nu_1 b_1 + \nu_2 b_2 \ge 1$;

(iii) whenever $b_1 \in \mathfrak{B}_1$, $b_2 \in \mathfrak{B}_2$ and $b_1 \cap b_2 = 0$, then $\nu_1 b_1 + \nu_2 b_2 \le 1$.

(b) Let X, Y_1, Y_2 be sets, and for $i \in \{1,2\}$ let $\mathcal{E}_i$ be an algebra of subsets of Y_i, $\nu_i : \mathcal{E}_i \to [0,1]$ an additive functional such that $\nu_i Y_i = 1$, and $f_i : X \to Y_i$ a function. Then the following are equiveridical:

(i) there is an additive functional $\mu : \mathcal{P}X \to [0,1]$ such that $\mu f_i^{-1}[E] = \nu_i E$ whenever $i \in \{1,2\}$ and $E \in \mathcal{E}_i$;

(ii) $f_1^{-1}[E_1] \cap f_2^{-1}[E_2] \ne \emptyset$ whenever $E_1 \in \mathcal{E}_1$, $E_2 \in \mathcal{E}_2$ and $\nu_1 E_1 + \nu_2 E_2 > 1$;

(iii) $\nu E_1 \le \nu E_2$ whenever $E_1 \in \mathcal{E}_1$, $E_2 \in \mathcal{E}_2$ and $f_1^{-1}[E_1] \subseteq f_2^{-1}[E_2]$.

proof (a)(i)⇒(iii) is elementary (and is a special case of 457A(i)⇒457A(iii)).

(iii)⇒(ii) If (iii) is true, and $b_1 \in \mathfrak{B}_1$, $b_2 \in \mathfrak{B}_2$ are such that $b_1 \cup b_2 = 1$, then $(1\setminus b_1)\cap(1\setminus b_2) = 0$, so

$$\nu_1 b_1 + \nu_2 b_2 = 2 - \nu_1(1\setminus b_1) - \nu_2(1\setminus b_2) \ge 1.$$

(ii)⇒(i) The point is that (ii) here implies (ii) of 457A. **P** Suppose that $i_0,\dots,i_n \in \{1,2\}$, $a_k \in \mathfrak{B}_{i_k}$ for $k \le n$ and $\sum_{k=0}^n \chi a_k \ge m\chi 1$ in $S(\mathfrak{A})$, where $m \in \mathbb{N}$. Set $K_j = \{k : k \le n,\ i_k = j\}$ for each j, $u = \sum_{k\in K_1} \chi a_k \in S(\mathfrak{B}_1)$, $v = \sum_{k\in K_2} \chi a_k \in S(\mathfrak{B}_2)$. Then we can express u as $\sum_{j=0}^{m_1} \chi c_j$ where $c_j \in \mathfrak{B}_1$ for each $j \le m_1$ and $c_0 \supseteq c_1 \supseteq \dots \supseteq c_{m_1}$ (see the proof of 361Ec). Taking $c_j = 0$ for $m_1 < j \le m$ if necessary,

we may suppose that $m_1 \geq m$. Similarly, $v = \sum_{j=0}^{m_2} \chi d_j$ where $m_2 \geq m$, $d_j \in \mathfrak{B}_2$ for each $j \leq m_2$ and $d_0 \supseteq \ldots \supseteq d_{m_2}$.

For $j < m$, set $b_j = 1 \setminus (c_j \cup d_{m-j-1})$. Then, because $b_j \cap c_j = 0$,

$$u \times \chi b_j = \sum_{r=0}^{m_1} \chi(c_r \cap b_j) = \sum_{r=0}^{j-1} \chi(c_r \cap b_j) \leq j\chi b_j,$$

and similarly $v \times \chi b_j \leq (m-j-1)\chi b_j$, so

$$m\chi b_j \leq (u+v) \times \chi b_j = u \times \chi b_j + v \times \chi b_j \leq (m-1)\chi b_j,$$

and b_j must be 0.

Thus $c_j \cup d_{m-j-1} = 1$ for every $j < m$. But this means that $\nu_1 c_j + \nu_2 d_{m-j-1} \geq 1$ for every $j < m$, so that

$$\begin{aligned}\sum_{k=0}^{n} \nu_{i_k} a_k &= \sum_{k \in K_1} \nu_1 a_k + \sum_{k \in K_2} \nu_2 a_k = \int u \, d\nu_1 + \int v \, d\nu_2 \\ &= \sum_{j=0}^{m_1} \nu_1 c_j + \sum_{j=0}^{m_2} \nu_2 d_j \geq \sum_{j=0}^{m-1} \nu_1 c_j + \nu_2 d_{m-1-j} \geq m,\end{aligned}$$

as required. **Q**

Because 457A(ii) implies 457A(i), we have the result.

(b) We can convert (i) and (ii) here into (a-i) and (a-iii) just above by the same translation as in 457B. So (i) and (ii) are equiveridical. As for (iii), this corresponds exactly to replacing E_2 by $Y_2 \setminus E_2$ in (ii).

***457D** The proof of 457A is based, at some remove, on the Hahn-Banach theorem, as applied in the proof of 391E-391F. An alternative proof uses the max-flow min-cut theorem of graph theory. To show the power of this method I apply it to an elaboration of 457C, as follows.

Proposition (Strassen 65) Let $\mathfrak{A}$ be a Boolean algebra and $\mathfrak{B}_1$, $\mathfrak{B}_2$ two subalgebras of $\mathfrak{A}$. Suppose that $\nu_i : \mathfrak{B}_i \to [0,1]$ are finitely additive functionals such that $\nu_1 1 = \nu_2 1 = 1$, and $\theta : \mathfrak{A} \to [0,\infty[$ another additive functional. Then the following are equiveridical:

(i) there is an additive functional $\mu : \mathfrak{A} \to [0,\infty[$ extending both the ν_i, and such that $\mu a \leq \theta a$ for every $a \in \mathfrak{A}$;

(ii) $\nu_1 b_1 + \nu_2 b_2 \leq 1 + \theta(b_1 \cap b_2)$ for every $b_1 \in \mathfrak{B}_1$, $b_2 \in \mathfrak{B}_2$.

proof (a) As usual in this context, (i)⇒(ii) is elementary; if $\mu \leq \theta$ extends both ν_j, and $b_j \in \mathfrak{B}_j$ for both j, then

$$\nu_1 b_1 + \nu_2 b_2 = \mu b_1 + \mu b_2 = \mu(b_1 \cup b_2) + \mu(b_1 \cap b_2) \leq 1 + \theta(b_1 \cap b_2).$$

(b) For the reverse implication, suppose to begin with (down to the end of (d) below) that $\mathfrak{A}$ is finite. Let I, J and K be the sets of atoms of $\mathfrak{B}_1$, $\mathfrak{B}_2$ and $\mathfrak{A}$ respectively. Consider the transportation network (V, E, γ) where

$$V = \{(0,0)\} \cup \{(b,1) : b \in I\} \cup \{(d,2) : d \in K\} \cup \{(c,3) : c \in J\} \cup \{(1,4)\},$$

$$E = \{e_b^0 : b \in I\} \cup \{e_d^1 : d \in K\} \cup \{e_d^2 : d \in K\} \cup \{e_c^3 : c \in J\},$$

where

for $b \in I$, e_b^0 runs from $(0,0)$ to $(b,1)$,
for $d \in K$, e_d^1 runs from $(b,1)$ to $(d,2)$, where b is the member of I including d,
for $d \in K$, e_d^2 runs from $(d,2)$ to $(c,3)$, where c is the member of J including d,
for $c \in J$, e_c^3 runs from $(c,3)$ to $(1,4)$.

Define the capacity $\gamma(e)$ of each link by setting

$$\gamma(e_b^0) = \nu_1 b \text{ for } b \in I,$$

$$\gamma(e_d^1) = \gamma(e_d^2) = \theta d \text{ for } d \in K,$$

$$\gamma(e^3_c) = \nu_2 c \text{ for } c \in J.$$

By the max-flow min-cut theorem (4A4N), there are a flow ϕ and a cut X of the same value; that is, we have a function $\phi : E \to [0,\infty[$ and a set $X \subseteq E$ such that

$$\sum_{e \text{ starts from } v} \phi(e) = \sum_{e \text{ ends at } v} \phi(e)$$

for every $v \in V \setminus \{(0,0),(1,4)\}$,

$$\phi(e) \le \gamma(e)$$

for every $e \in E$,

$$\sum_{e \text{ starts from } (0,0)} \phi e = \sum_{e \text{ ends at } (1,4)} \phi e = \sum_{e \in X} \gamma(e),$$

and there is no path from $(0,0)$ to $(1,4)$ using only links in $E \setminus X$.

Now, for any $d \in K$, there is exactly one link e^1_d ending at d and exactly one link e^2_d starting from d. So $\phi(e^1_d) = \phi(e^2_d)$, and we may define an additive functional μ on $\mathfrak{A}$ by setting

$$\mu a = \sum_{d \in K, d \subseteq a} \phi(e^1_d) = \sum_{d \in K, d \subseteq a} \phi(e^2_d)$$

for every $a \in \mathfrak{A}$.

(c)(i) $\mu b \le \nu_1 b$ for every $b \in \mathfrak{B}_1$. **P** Because I is the set of atoms of the finite Boolean algebra $\mathfrak{B}_1$, it is enough to show that $\mu b \le \nu_1 b$ for every $b \in I$. Now, for such b,

$$\begin{aligned}\mu b &= \sum_{d \in K, d \subseteq b} \mu d = \sum_{d \in K, d \subseteq b} \phi(e^1_d) = \sum_{e \text{ starts from } (b,1)} \phi(e) \\ &= \sum_{e \text{ ends at } (b,1)} \phi(e) = \phi(e^0_b) \le \gamma(e^0_b) = \nu_1 b,\end{aligned}$$

because the only link ending at $(b,1)$ is e^0_b. **Q**

(ii) Similarly, because the only link starting at $(c,3)$ has capacity $\nu_2 c$, $\mu c \le \nu_2 c$ for every $c \in J$. But this means that $\mu c \le \nu_2 c$ for every $c \in \mathfrak{B}_2$.

(iii) In third place, because

$$\mu d = \phi(e^1_d) \le \gamma(e^1_d) = \theta d$$

for every $d \in K$, $\mu a \le \theta a$ for every $a \in \mathfrak{A}$.

(d) (The key.) $\mu 1 \ge 1$. **P** We have

$$\begin{aligned}\mu 1 &= \sum_{d \in K} \mu d = \sum_{d \in K} \phi(e^1_d) \\ &= \sum_{b \in I} \sum_{d \in K, d \subseteq b} \phi(e^1_d) = \sum_{b \in I} \sum_{e \text{ starts from } (b,1)} \phi(e) \\ &= \sum_{b \in I} \sum_{e \text{ ends at } (b,1)} \phi(e) = \sum_{e \text{ starts from } (0,0)} \phi(e) = \sum_{e \in X} \gamma(e).\end{aligned}$$

Set

$$\begin{aligned}b^* &= \sup\{b : b \in I,\, e^0_b \in X\} \in \mathfrak{B}_1, \\ a^*_1 &= \sup\{d : d \in K,\, e^1_d \in X\}, \\ a^*_2 &= \sup\{d : d \in K,\, e^2_d \in X\}, \\ c^* &= \sup\{c : c \in J,\, e^3_c \in X\} \in \mathfrak{B}_2.\end{aligned}$$

For any $d \in K$, we have a four-link path $e^0_b, e^1_d, e^2_d, e^3_c$ from $(0,0)$ to $(1,4)$, where $b \in I$, $c \in J$ are the atoms of $\mathfrak{B}_1$, $\mathfrak{B}_2$ including d. At least one of the links in this path must belong to X, so that d is included in $b^* \cup a^*_1 \cup a^*_2 \cup c^*$. Thus, writing $a = (1 \setminus b^*) \cap (1 \setminus c^*)$, $a \subseteq a^*_1 \cup a^*_2$ and $\theta a \le \theta a^*_1 + \theta a^*_2$. But this means that

$$\begin{aligned}\mu 1 &= \sum_{e\in X}\gamma(e)\\ &= \sum_{b\in I,e_b^0\in X}\gamma(e_b^0)+\sum_{d\in K,e_d^1\in X}\gamma(e_d^1)+\sum_{d\in K,e_d^2\in X}\gamma(e_d^2)+\sum_{c\in J,e_c^3\in X}\gamma(e_c^3)\\ &= \sum_{b\in I,e_b^0\in X}\nu_1 b+\sum_{d\in K,e_d^1\in X}\theta d+\sum_{d\in K,e_d^2\in X}\theta d+\sum_{c\in J,e_c^3\in X}\nu_2 c\\ &= \nu_1 b^*+\theta a_1^*+\theta a_2^*+\nu_2 c^*\geq \nu_1 b^*+\theta((1\setminus b^*)\cap(1\setminus c^*))+\nu_2 c^*\\ &\geq \nu_1 b^*+\nu_1(1\setminus b^*)+\nu_2(1\setminus c^*)-1+\nu_2 c^*\end{aligned}$$

(applying the hypothesis (ii))

$$= 1,$$

as claimed. **Q**

Since we already know that $\nu_1 1 = 1$ and that $\mu b \leq \nu_1 b$ for every $b \in \mathfrak{B}_1$, we must have $\mu 1 = 1$ and $\mu b = \nu_1 b$ for every $b \in \mathfrak{B}$, so that μ extends ν_1. Similarly, μ extends ν_2.

(e) Thus the proposition is proved in the case in which $\mathfrak{A}$ is finite. In the general case, for each finite subset K of $\mathfrak{A}$ write $\mathfrak{A}_K$ for the subalgebra of $\mathfrak{A}$ generated by K. Then (b)-(d) tell us that there is a non-negative additive functional μ_K on $\mathfrak{A}_K$, dominated by θ on $\mathfrak{A}_K$, agreeing with ν_1 on $\mathfrak{A}_K \cap \mathfrak{B}_1$ and agreeing with ν_2 on $\mathfrak{A}_K \cap \mathfrak{B}_2$. Let μ be any cluster point of the μ_K in $[0,1]^{\mathfrak{A}}$ as K increases through the finite subsets of $\mathfrak{A}$; then μ will be a non-negative additive functional on $\mathfrak{A}$, dominated by θ, and extending ν_1 and ν_2.

This proves the result.

457E Proposition Let X be a non-empty set and $\langle\nu_i\rangle_{i\in I}$ a family of probability measures on X satisfying the conditions of Lemma 457A, taking $\mathfrak{A} = \mathcal{P}X$ and $\mathfrak{B}_i = \operatorname{dom}\nu_i$ for each i. Suppose that there is a countably compact class $\mathcal{K} \subseteq \mathcal{P}X$ such that every ν_i is inner regular with respect to $\mathcal{K}$. Then there is a probability measure μ on X extending every ν_i.

proof If $I = \emptyset$ this is trivial. Otherwise, by 457A, there is a finitely additive functional ν on $\mathcal{P}X$ extending every ν_i. Now 413S tells us that there is a complete measure μ on X such that $\mu X \leq \nu X$ and $\mu K \geq \nu K$ for every $K \in \mathcal{K}$. In this case, for any $i \in I$ and $E \in \mathrm{T}_i = \operatorname{dom}\nu_i$, we must have

$$\begin{aligned}\mu_* E &\geq \sup_{K\in\mathcal{K},K\subseteq E}\mu K \geq \sup_{K\in\mathcal{K}\cap\operatorname{dom}\nu_i,K\subseteq E}\mu K\\ &\geq \sup_{K\in\mathcal{K}\cap\operatorname{dom}\nu_i,K\subseteq E}\nu K = \sup_{K\in\mathcal{K}\cap\operatorname{dom}\nu_i,K\subseteq E}\nu_i K = \nu_i E.\end{aligned}$$

In particular, $\mu X \geq \nu_i X = 1$. Now

$$\mu^* E = 1-\mu_*(X\setminus E)\leq 1-\nu_i(X\setminus E)=\nu_i E$$

for any $E \in \mathrm{T}_i$; as μ is complete, μE is defined and equal to $\nu_i E$ for every $E \in \mathrm{T}_i$, and μ extends ν_i, as required.

457F Proposition (a) Let (X,Σ,μ) be a perfect probability space and (Y,T,ν) any probability space. Write $\Sigma\otimes\mathrm{T}$ for the algebra of subsets of $X\times Y$ generated by $\{E\times F : E\in\Sigma, F\in\mathrm{T}\}$. Suppose that $Z\subseteq X\times Y$ is such that

(i) Z is expressible as the intersection of a sequence in $\Sigma\otimes\mathrm{T}$,

(ii) $Z\cap(E\times F)\neq\emptyset$ whenever $E\in\Sigma$, $F\in\mathrm{T}$ are such that $\mu E+\nu F>1$.

Then there is a probability measure λ on Z such that the maps $(x,y)\mapsto x : Z\to X$ and $(x,y)\mapsto y : Z\to Y$ are both inverse-measure-preserving.

(b) Let $\langle(X_i,\Sigma_i,\mu_i)\rangle_{i\in I}$ be a family of perfect probability spaces. Write $\bigotimes_{i\in I}\Sigma_i$ for the algebra of subsets of $X=\prod_{i\in I}X_i$ generated by $\{\{x : x\in X, x(i)\in E\} : i\in I, E\in\Sigma_i\}$. Suppose that $Z\subseteq X$ is such that

(i) Z is expressible as the intersection of a sequence in $\bigotimes_{i\in I}\Sigma_i$,

(ii) whenever $i_0, \dots, i_n \in I$ and $E_k \in \Sigma_{i_k}$ for $k \leq n$, there is a $z \in Z$ such that $\#(\{k : k \leq n, z(i_k) \in E_k\}) \geq \sum_{k=0}^{n} \mu_{i_k} E_k$.

Then there is a perfect probability measure λ on Z such that $z \mapsto z(i) : Z \to X_i$ is inverse-measure-preserving for every $i \in I$.

proof (a) Apply 457Cb to the coordinate maps $f_1 : Z \to X$ and $f_2 : Z \to Y$. The condition (ii) here shows that 457C(b-ii) is satisfied, so there is an additive functional $\theta : \mathcal{P}Z \to [0,1]$ such that $\theta f_1^{-1}[E] = \mu E$ for every $E \in \Sigma$ and $\theta f_2^{-1}[F] = \nu F$ for every $F \in \mathrm{T}$.

Define $\theta' : \Sigma \otimes \mathrm{T} \to [0,1]$ by setting $\theta' W = \theta(Z \cap W)$ for every $W \in \Sigma \otimes \mathrm{T}$. Then $\theta'(E \times Y) = \mu E$ for every $E \in \Sigma$ and $\theta'(X \times F) = \nu F$ for every $F \in \mathrm{T}$. Because μ is perfect, θ' has an extension to a measure $\tilde{\lambda}$ defined on $\Sigma \widehat{\otimes} \mathrm{T}$ (454C). Now Z is supposed to be expressible as $\bigcap_{n \in \mathbb{N}} W_n$ where $W_n \in \Sigma \otimes \mathrm{T}$ for every n; since

$$\tilde{\lambda} W_n = \theta' W_n = \theta(Z \cap W_n) = \theta Z = 1$$

for every n, $\tilde{\lambda} Z = 1$. So if we take λ to be the subspace measure on Z induced by $\tilde{\lambda}$, λ will be a probability measure on Z. If $E \in \Sigma$, then

$$\begin{aligned} \lambda(Z \cap (E \times Y)) &= \tilde{\lambda}(Z \cap (E \times Y)) = \tilde{\lambda}(E \times Y) \\ &= \theta'(E \times Y) = \theta(Z \cap (E \times Y)) = \mu E. \end{aligned}$$

So $f_1 : Z \to X$ is inverse-measure-preserving for λ and μ. Similarly, $f_2 : Z \to Y$ is inverse-measure-preserving for λ and ν.

(b) We use the same ideas, but appealing to 457B and 454D instead of 457Cb and 454C. Taking $f_i : X \to X_i$ to be the coordinate map for each $i \in I$, (ii) here, with 457B, tells us that there is an additive functional $\theta : \mathcal{P}Z \to [0,1]$ such that $\theta f_i^{-1}[E] = \mu_i E$ whenever $i \in I$ and $E \in \Sigma_i$.

Define $\theta' : \bigotimes_{i \in I} \Sigma_i \to [0,1]$ by setting $\theta' W = \theta(Z \cap W)$ for every $W \in \bigotimes_{i \in I} \Sigma_i$. Then

$$\theta'\{x : x \in X, x(i) \in E\} = \theta\{z : z \in Z, z(i) \in E\} = \mu_i E$$

whenever $i \in I$ and $E \in \Sigma_i$. Because every μ_i is perfect, θ' has an extension to a perfect measure $\tilde{\lambda}$ defined on $\widehat{\bigotimes}_{i \in I} \Sigma_i$ (454D). Now Z is supposed to be expressible as $\bigcap_{n \in \mathbb{N}} W_n$ where $W_n \in \bigotimes_{i \in I} \Sigma_i$ for every n; since

$$\tilde{\lambda} W_n = \theta' W_n = \theta(Z \cap W_n) = \theta Z = 1$$

for every n, $\tilde{\lambda} Z = 1$. So if we take λ to be the subspace measure on Z induced by $\tilde{\lambda}$, λ will be a probability measure on Z; by 451Dc, λ is perfect. If $i \in I$ and $E \in \Sigma_i$, then

$$\begin{aligned} \lambda\{z : z \in Z, z(i) \in E\} &= \tilde{\lambda}\{x : x \in X, x(i) \in E\} \\ &= \theta'\{x : x \in X, x(i) \in E\} = \theta\{z : z \in Z, z(i) \in E\} = \mu_i E. \end{aligned}$$

So $z \mapsto z(i) : Z \to X_i$ is inverse-measure-preserving for λ and μ_i for every $i \in I$, as required.

457G Proposition Let X be a set and $\langle \mu_i \rangle_{i \in I}$ a family of probability measures on X which is upwards-directed in the sense that for any $i, j \in I$ there is a $k \in I$ such that μ_k extends both μ_i and μ_j. Suppose that for any countable $J \subseteq I$ there is a measure on X extending μ_i for every $i \in J$. Then there is a measure on X extending μ_i for every $i \in I$.

proof Set $\Sigma_i = \operatorname{dom} \mu_i$ for each $i \in I$. Because $\langle \mu_i \rangle_{i \in I}$ is upwards-directed, $\mathrm{T} = \bigcup_{i \in I} \Sigma_i$ is an algebra of subsets of X, and we have a finitely additive functional $\nu : \mathrm{T} \to [0,1]$ defined by saying that $\nu E = \mu_i E$ whenever $i \in I$ and $E \in \Sigma_i$. Now if $\langle E_n \rangle_{n \in \mathbb{N}}$ is any non-increasing sequence in T with empty intersection, there is a countable set $J \subseteq I$ such that $E_n \subseteq \bigcup_{i \in J} \Sigma_i$ for every $n \in \mathbb{N}$. We are told that there is a measure λ on X extending μ_i for every $i \in J$; now $\nu E_n = \lambda E_n$ for every $n \in \mathbb{N}$, so $\lim_{n \to \infty} \nu E_n = 0$. By 413K, ν has an extension to a measure on X, which of course extends every μ_i.

457H Example Set $X = \{(x, y) : 0 \leq x < y \leq 1\} \subseteq [0,1]^2$. Write $\pi_1, \pi_2 : X \to \mathbb{R}$ for the coordinate maps, and μ_L for Lebesgue measure on $[0,1]$, with Σ_L its domain.

(a) There is a finitely additive functional $\nu : \mathcal{P}X \to [0,1]$ such that $\nu\pi_i^{-1}[E] = \mu_L E$ whenever $i \in \{1,2\}$ and $E \in \Sigma_L$. **P** If E_1, $E_2 \in \Sigma_L$ and $\mu_L E_1 + \mu_L E_2 > 1$, then neither is empty and $\inf E_1 < \sup E_2$, so there are $x \in E_1$, $y \in E_2$ such that $x < y$, and $(x,y) \in \pi_1^{-1}[E_1] \cap \pi_2^{-1}[E_2]$. So the result follows by 457Cb. **Q**

(b) However, there is no measure μ on X for which both π_1 and π_2 are inverse-measure-preserving. **P?** If there were,

$$\int \pi_1(x,y)\mu(d(x,y)) = \int x\mu_L(dx) = \int y\mu_L(dy) = \int \pi_2(x,y)\mu(d(x,y))$$

by 235I; but $\pi_1(x,y) < \pi_2(x,y)$ for every $(x,y) \in X$, so this is impossible. **XQ**

(c) If we write $\mathrm{T}_i = \{\pi_i^{-1}[E] : E \subseteq [0,1] \text{ is Borel}\}$ for each i, then we have a measure ν_i with domain T_i defined by setting $\nu_i\pi_i^{-1}[E] = \mu_L E$ for each Borel set $E \subseteq [0,1]$. Now ν_1 and ν_2 have no common extension to a Borel measure on X, even though X is a Polish space and each ν_i is a compact measure, being inner regular with respect to the compact class $\mathcal{K}_i = \{\pi_i^{-1}[K] : K \subseteq]0,1[\text{ is compact}\}$. (The trouble is that $\mathcal{K}_1 \cup \mathcal{K}_2$ is *not* compact, so we cannot apply 457E.)

457I Example Let μ_L be Lebesgue measure on $[0,1]$ and Σ_L its domain. Set

$$X = \{(\xi_1,\xi_2,\xi_3) : 0 \le \xi_i \le 1 \text{ for each } i, \textstyle\sum_{i=1}^3 \xi_i \le \frac{3}{2}, \sum_{i=1}^3 \xi_i^2 \le 1\}.$$

For $1 \le i \le 3$ set $\pi_i(x) = \xi_i$ for $x = (\xi_1,\xi_2,\xi_3) \in X$.

(a) If $E_i \in \Sigma_L$ for $i \le 3$, then there is an $x \in X$ such that $\#(\{i : \pi_i(x) \in E_i\}) \ge \sum_{i=1}^3 \mu_L E_i$. **P** Set $\alpha_i = \inf(E_i \cup \{1\})$ for each i, and set

$$m = \lceil \textstyle\sum_{i=1}^3 \mu_L E_i \rceil \le \lceil \sum_{i=1}^3 1 - \alpha_i \rceil = 3 - \lfloor \sum_{i=1}^3 \alpha_i \rfloor,$$

so that $\sum_{i=1}^3 \alpha_i < 4 - m$. Take $\xi_i \in E_i \cup \{1\}$ such that $\sum_{i=1}^3 \xi_i < 4 - m$. It will be enough to consider the case in which $\xi_1 \le \xi_2 \le \xi_3$.

(i) If $m = 1$, then $\sum_{i=1}^3 \xi_i < 3$ so $\xi_1 < 1$ and $\xi_1 \in E_1$. Set $x = (\xi_1, 0, 0)$; then $x \in X$ and

$$\#(\{i : \pi_i(x) \in E_i\}) \ge 1 \ge \textstyle\sum_{i=1}^3 \mu_L E_i.$$

(ii) If $m = 2$, then $\sum_{i=1}^3 \xi_i < 2$ so $\xi_2 < 1$ and $\xi_1 \in E_1$, $\xi_2 \in E_2$. Set $x = (\xi_1,\xi_2,0)$. We have $\xi_1 + \xi_2 \le \frac{4}{3} \le \frac{3}{2}$. Also

$$\xi_2 \le \tfrac{1}{2}(\xi_2 + \xi_3) \le 1 - \tfrac{1}{2}\xi_1,$$

so

$$\xi_1^2 + \xi_2^2 \le \xi_1^2 + (1 - \tfrac{1}{2}\xi_1)^2 = 1 - \xi_1 + \tfrac{5}{4}\xi_1^2 \le 1$$

because $\xi_1 \le \frac{2}{3} \le \frac{4}{5}$. So $x \in X$ and

$$\#(\{i : \pi_i(x) \in E_i\}) \ge 2 \ge \textstyle\sum_{i=1}^3 \mu_L E_i.$$

(iii) If $m = 3$ then $\sum_{i=1}^3 \xi_i < 1$ so $\xi_i \in E_i$ for every i; set $x = (\xi_1,\xi_2,\xi_3)$. Since $\sum_{i=1}^3 \xi_i^2 \le \sum_{i=1}^3 \xi_i \le 1$, $x \in X$ and

$$\#(\{i : \pi_i(x) \in E_i\}) = 3 \ge \textstyle\sum_{i=1}^3 \mu_L E_i.$$

Putting these together, we have the result. **Q**

(b) There is no finitely additive functional ν on X such that $\nu\pi_i^{-1}[E] = \mu E$ for each i and every $E \in \Sigma_L$. **P?** Suppose there were. Set $\mathrm{T}_i = \{\pi_i^{-1}[E] : E \in \Sigma_L\}$ and $\nu_i = \nu \restriction \mathrm{T}_i$ for each i. Then ν_i is a probability measure on X; moreover, because X is compact, $\pi_i^{-1}[K]$ is compact for every compact $K \subseteq [0,1]$, so ν_i is inner regular with respect to the compact subsets of X. By 457E, the ν_i have a common extension to a countably additive measure μ. Now

$$\int_X \xi_1 + \xi_2 + \xi_3 \, \mu(dx) = 3 \int_0^1 t \, dt = \frac{3}{2},$$

so we must have $\xi_1 + \xi_2 + \xi_3 = \frac{3}{2}$ for μ-almost every x; similarly,

$$\int_X \xi_1^2 + \xi_2^2 + \xi_3^2 \, \mu(dx) = 3 \int_0^1 t^2 \, dt = 1,$$

so we must have $\xi_1^2 + \xi_2^2 + \xi_3^2 = 1$ for μ-almost every x. Since

$$(\tfrac{3}{2} - \xi_3)^2 = (\xi_1 + \xi_2)^2 \leq 2(\xi_1^2 + \xi_2^2) \leq 2(1 - \xi_3^2)$$

for almost every x, $\xi_3 - \xi_3^2 \geq \frac{1}{12}$ for almost every x, which is impossible, since $\mu\{x : \xi_3 \leq \frac{1}{2} - \frac{1}{\sqrt{6}}\} > 0$. **XQ**

457J Example There are a set X and a family $\langle \mu_i \rangle_{i \in I}$ of probability measures on X such that (i) for every countable set $J \subseteq I$ there is a measure on X extending μ_i for every $i \in J$ (ii) there is no measure on X extending μ_i for every $i \in I$.

proof By 439Fc, there is an uncountable universally negligible subset of $[0,1]$. Because $[0,1]$ and $\mathcal{P}\mathbb{N}$ are uncountable Polish spaces, they have isomorphic Borel structures (424Cb), so there is an uncountable universally negligible set $X_0 \subseteq \mathcal{P}\mathbb{N}$. The map $a \mapsto \mathbb{N} \setminus a$ is an autohomeomorphism of $\mathcal{P}\mathbb{N}$, so $X_1 = \{\mathbb{N} \setminus a : a \in X_0\}$ is universally negligible, and $X = X_0 \cup X_1$ is universally negligible (439Cb).

For $n \in \mathbb{N}$, set $E_n = \{a : n \in a \in X\}$ and $\Sigma_n = \{\emptyset, E_n, X \setminus E_n, X\}$; note that, because X is closed under complementation, neither E_n nor $X \setminus E_n$ is empty, and we have a probability measure μ_n with domain Σ_n defined by setting $\mu_n E_n = \mu_n(X \setminus E_n) = \frac{1}{2}$. Next, for $a \in X$, set $\Sigma'_a = \{\emptyset, \{a\}, X \setminus \{a\}, X\}$, and let μ'_a be the probability measure with domain Σ'_a defined by setting $\mu'_a\{a\} = 0$.

If $J \subseteq X$ is countable, then there is a probability measure on X extending μ_n for every $n \in \mathbb{N}$ and μ'_a for every $a \in J$. **P** Because X_0 is uncountable, there is a $b \in X_0$ such that neither b nor $b' = \mathcal{P}\mathbb{N} \setminus b$ belongs to J. Let μ be the probability measure with domain $\mathcal{P}X$ defined by setting $\mu\{b\} = \mu\{b'\} = \frac{1}{2}$; this extends all the μ_n and all the μ'_a for $a \in J$. **Q**

? Suppose, if possible, that μ is a measure on X extending every μ_n and every μ'_a. In this case, because μ extends every μ_n, its domain includes the Borel σ-algebra $\mathcal{B}$ of X, and $\mu \restriction \mathcal{B}$ is a Borel probability measure on X. Since X is universally negligible, there is a point $a \in X$ such that $\mu\{a\} > 0$; in which case μ cannot extend μ'_a. **X**

Thus the μ_n, μ'_a constitute a family of the kind required.

457X Basic exercises (a) Let X be a non-empty set and $\langle \nu_i \rangle_{i \in I}$ a family of probability measures on X satisfying the conditions of Lemma 457A, taking $\mathfrak{A} = \mathcal{P}X$ and $\mathfrak{B}_i = \operatorname{dom} \nu_i$ for each i. Suppose that there is a totally finite measure θ on X such that θE is defined and greater than or equal to $\nu_i E$ whenever $i \in I$ and ν_i measures E. Show that there is a measure on X extending every ν_i.

(b) Find a set X and non-negative additive functionals μ_1, μ_2 defined on subalgebras of $\mathcal{P}X$ which agree on $\operatorname{dom} \mu_1 \cap \operatorname{dom} \mu_2$ but have no common extension to a non-negative additive functional. (*Hint*: take $\#(X) = 3$.)

(c) Let $\mathfrak{A}$ be a Boolean algebra and $\langle \nu_i \rangle_{i \in I}$ a family of non-negative finitely additive functionals, each ν_i being defined on a subalgebra $\mathfrak{B}_i$ of $\mathfrak{A}$. Show that if any finite number of the ν_i have a common extension to an additive functional on a subalgebra of $\mathfrak{A}$, then the whole family has a common extension to an additive functional on the whole algebra $\mathfrak{A}$.

(d) Set $X = \{0,1,2\}$ and in the algebra $\mathcal{P}X$ let $\mathfrak{B}_i$ be the subalgebra $\{0, \{i\}, X \setminus \{i\}, X\}$ for each i. Let $\nu_i : \mathfrak{B}_i \to [0,1]$ be the additive functional such that $\nu_i\{i\} = \frac{1}{2}$, $\nu_i X = 1$. Show that any pair of ν_0, ν_1, ν_2 have a common extension to an additive functional on $\mathcal{P}X$, but that the three together have no such extension.

(e) Let $\mathfrak{A}$ be a Boolean algebra, $\mathfrak{B}$ a subalgebra of $\mathfrak{A}$, and $\nu : \mathfrak{B} \to [0, \infty[$, $\theta : \mathfrak{A} \to [0, \infty[$ additive functionals such that $\nu b \leq \theta b$ for every $b \in \mathfrak{B}$. Show directly, without using either 457D or 391F, that there

is an additive functional $\mu : \mathfrak{A} \to [0,\infty[$, extending ν, such that $\mu a \leq \theta a$ for every $a \in \mathfrak{A}$. (*Hint*: first consider the case in which $\mathfrak{A}$ is the algebra generated by $\mathfrak{B} \cup \{c\}$.)

>(f) Let $(Y_1, \mathfrak{S}_1, \mathrm{T}_1, \nu_1)$ and $(Y_2, \mathfrak{S}_2, \mathrm{T}_2, \nu_2)$ be Radon probability spaces and $X \subseteq Y_1 \times Y_2$ a closed set. Show that the following are equiveridical: (i) there is a measure on X such that the coordinate map from X to Y_i is inverse-measure-preserving for both i; (ii) there is a Radon measure on X such that the coordinate map from X to Y_i is inverse-measure-preserving for both i; (iii) for every compact $K \subseteq Y_1$, $\nu_1 K \leq \nu_2^*(X[K])$. (*Hint*: for (iii)⇒(ii), use 457C to show that there is a finitely additive functional ν on $\mathcal{P}X$ of the required type; now observe that ν must give large mass to compact subsets of X, and apply 413S.)

(g) Let $X \subseteq [0,1]^2$ be a Lebesgue measurable set such that $X \cap (E \times F)$ is not negligible for any non-negligible sets E, $F \subseteq [0,1]$. (For the construction of such sets, see the notes to §325.) Show that there is a Radon measure on X such that both the coordinate projections from X to $[0,1]$ are inverse-measure-preserving, where $[0,1]$ is given Lebesgue measure. (*Hint*: show that there is a measure-preserving bijection ϕ between conegligible subsets of $[0,1]$ which is covered by X; ϕ can be taken to be of the form $\phi(x) = x - \alpha_n$ for $x \in E_n$.)

(h) Set $X = \{(t, 2t) : 0 \leq t \leq \frac{1}{2}\} \cup \{(t, 2t-1) : \frac{1}{2} \leq t \leq 1\}$. Show that there is a Radon measure on X for which both the coordinate maps onto $[0,1]$ are inverse-measure-preserving, but that X does not include the graph of any measure-preserving bijection between conegligible subsets of $[0,1]$.

(i) Let X be the eighth-sphere $\{x : x \in [0,1]^3, \|x\| = 1\}$. Show that there is a measure on X such that all three coordinate maps from X onto $[0,1]$ are inverse-measure-preserving. (*Hint*: 265Xe.)

(j) Set $X = \{x : x \in [0,1]^3, \xi_1 + \xi_2 + \xi_3 = \frac{3}{2}\}$. Show that there is a measure on X such that all the coordinate maps from X onto $[0,1]$ are inverse-measure-preserving. (*Hint*: note that X is a regular hexagon; try one-dimensional Hausdorff measure on its boundary.)

(k) Explain how to adapt the example in 457J to provide a family $\langle \mu_i \rangle_{i \in I}$ of probability measures on a set X such that (i) $\langle \mu_i \rangle_{i \in I}$ is upwards-directed (iii) there is no measure on X extending μ_i for every $i \in I$.

457Y Further exercises (a) Show that for any $n \geq 2$ there are a finite set X and a family $\langle \mu_i \rangle_{i \leq n}$ of measures on X such that $\{\mu_i : i \leq n, i \neq j\}$ have a common extension to a measure on X for every $j \leq n$, but the whole family $\{\mu_i : i \leq n\}$ has no such extension.

(b) Show that the example in 457H has the property: if f_i is a ν_i-integrable real-valued function for each i, and $\int f_1 d\nu_1 + \int f_2 d\nu_2 < 1$, then there is an $(x,y) \in \operatorname{dom} f_1 \cap \operatorname{dom} f_2$ such that $f_1(x,y) + f_2(x,y) < 1$.

(c) Suppose we replace the set X in 457H with $X' = X \cup \{(x,x) : x \in [0, \frac{1}{2}]\}$, and write ν_i' for the measures on X' defined by the coordinate projections. Show that (i) if f_i is a ν_i'-integrable real-valued function on X' for each i, and $\int f_1 d\nu_1' + \int f_2 d\nu_2' \leq 1$, then there is an $(x,y) \in \operatorname{dom} f_1 \cap \operatorname{dom} f_2$ such that $f_1(x,y) + f_2(x,y) \leq 1$ (ii) there is no measure on X' extending both ν_i'.

(d) In 457Xj, show that there are many Radon measures on X such that all the coordinate maps from X onto $[0,1]$ are inverse-measure-preserving.

457Z Problems (a) Characterize the sets $X \subseteq [0,1]^2$ for which there is a measure on X such that both the projections from X to $[0,1]$ are inverse-measure-preserving.

(b) Set $X = \{x : x \in [0,1]^3, \|x\| = 1\}$. Is there more than one Radon measure on X for which all the coordinate maps from X onto $[0,1]$ are inverse-measure-preserving? (See 457Xi, 457Yd.)

457 Notes and comments In the context of this section, as elsewhere (compare 391E-391G and 391J), finitely additive extensions, as in 457A-457D, generally present easier problems than countably additive extensions. So techniques for turning additive functionals into measures (391D, 454C, 454D, 457E, 457G)

are very valuable. Note that 457D offers possibilities in this direction: if θ there is countably additive, μ also will be (457Xa).

457H-457J demonstrate obstacles which can arise when seeking countably additive extensions even when finitely additive extensions give no difficulty. For finitely additive extensions a problem can arise at any finite number of measures (see 457Ya), but there is no further obstruction with infinite families (457Xc). For countably additive measures we have a positive result (457G) only under very restricted circumstances; relaxing any of the hypotheses can lead to failure (457J, 457Xk). Even in the apparently concrete case in which we have an open or closed set $X \subseteq [0,1]^2$ and we are seeking a measure on X with prescribed image measures on each coordinate, there can be surprises (457H, 457Xg, 457Xh), and I know of no useful description of the sets for which such a measure can be found (457Za).

The two-dimensional case has a special feature: when verifying the conditions (ii) or (iii) in 457A, or the condition (ii) of 457B, it is enough to consider only one set associated with each coordinate (457C). Put another way, in conditions (iv) and (v) of 457A it is enough to examine characteristic functions. This is not the case as soon as we have three coordinates (457I).

458 Relative independence and relative products

Stochastic independence is one of the central concepts of probability theory, and pervades measure theory. We come now to a generalization of great importance. If X_1, X_2 and Y are random variables, we may find that X_1 and X_2 are 'relatively independent over Y', or 'independent when conditioned on Y', in the sense that if we know the value of Y, then we learn nothing further about one of the X_i if we are told the value of the other. For any stochastic process, where information comes to us piecemeal, this idea is likely to be fundamental. In this section I set out a general framework for discussion of relative independence (458A), introducing relative distributions (458C) and relative independence in measure algebras (458H). In the second half of the section I look at 'relative product measures' (458I, 458L), giving the basic existence theorems (458J, 458N, 458O).

458A Relative independence Let (X, Σ, μ) be a probability space and T a σ-subalgebra of Σ.

(a) I say that a family $\langle E_i\rangle_{i\in I}$ in Σ is **relatively (stochastically) independent over** T if whenever $J \subseteq I$ is finite and not empty, and g_i is a conditional expectation of χE_i on T for each $i \in J$, then $\mu(\bigcap_{i\in J} E_i) = \int \prod_{i\in J} g_i d\mu$. (Note that $\int \prod_{i\in J} g_i d\mu$ does not depend on which conditional expectation g_i we take.) A family $\langle \Sigma_i\rangle_{i\in I}$ of σ-subalgebras of Σ is **relatively independent** over T if $\langle E_i\rangle_{i\in I}$ is relatively independent over T whenever $E_i \in \Sigma_i$ for every $i \in I$.

(b) I say that a family $\langle f_i\rangle_{i\in I}$ in $\mathcal{L}^0(\mu)$ (the space of almost-everywhere-defined virtually measurable real-valued functions, or 'random variables') is **relatively independent over** T if $\langle \Sigma_i\rangle_{i\in I}$ is relatively independent over T (with respect to the completion of μ), where Σ_i is the σ-algebra defined by f_i in the sense of 272C, that is, the σ-algebra generated by $\{f_i^{-1}[F] : F \subseteq \mathbb{R} \text{ is a Borel set}\}$.

(c) I remark at once that a family of σ-algebras or random variables is relatively independent iff every finite subfamily is (cf. 272Bb).

458B It is sometimes useful to know that 'relative independence' can be defined without using the apparatus of conditional expectations.

Lemma Let (X, Σ, μ) be a probability space, T_0 a σ-subalgebra of Σ, and $\langle \Sigma_i\rangle_{i\in I}$ a family of σ-subalgebras of Σ. Let $\mathbb{T}$ be the family of finite subalgebras of T. For $\Lambda \in \mathbb{T}$ write $\mathcal{A}_\Lambda$ for the set of non-negligible atoms in Λ. For non-empty finite $J \subseteq I$ and $\langle E_i\rangle_{i\in J} \in \prod_{i\in J} \Sigma_i$, set

$$\phi_\Lambda(\langle E_i\rangle_{i\in J}) = \sum_{H\in\mathcal{A}_\Lambda} \mu H \cdot \prod_{i\in J} \frac{\mu(E_i\cap H)}{\mu H}.$$

Then $\langle \Sigma_i\rangle_{i\in I}$ is relatively independent over T iff $\lim_{\Lambda\in\mathbb{T},\Lambda\uparrow} \phi_\Lambda(\langle E_i\rangle_{i\in J}) = \mu(\bigcap_{i\in J} E_i)$ whenever $J \subseteq I$ is finite and not empty and $E_i \in \Sigma_i$ for every $i \in J$.

proof (a) The point is just that if $J \subseteq I$ is finite and not empty, $E_i \in \Sigma_i$ for $i \in J$, and g_i is a conditional expectation of χE_i on T for each i, then $\int \prod_{i\in J} g_i d\mu = \lim_{\Lambda\uparrow} \phi_\Lambda(\langle E_i\rangle_{i\in J})$. **P** Adjusting each g_i on a negligible set if necessary, we may suppose that it is T-measurable, defined everywhere on X and takes values between 0 and 1.

Fix $n \in \mathbb{N}$ for the moment. Let Λ_n be the finite subalgebra of T generated by sets of the form $\{x : g_i(x) \leq 2^{-n}k\}$ for $i \in J$ and $1 \leq k \leq 2^n + 1$, and Λ any finite subalgebra of Σ_0 including Λ_n. If H is an atom of Λ and $\mu H > 0$, then there are integers k_i, for $i \in J$, $2^{-n}k_i \leq g_i(x) < 2^{-n}(k_i + 1)$ for every $i \in J$ and $x \in H$. So

$$2^{-n}k_i \leq \frac{\mu_i(E\cap H)}{\mu H} < 2^{-n}(k_i + 1)$$

for each i. Accordingly $\phi_\Lambda(\langle E_i\rangle_{i\in J})$ lies between $\sum_{H\in\mathcal{A}_\Lambda} \mu H \cdot \prod_{i\in J} 2^{-n}k_i$ and $\sum_{H\in\mathcal{A}_\Lambda} \mu H \cdot \prod_{i\in J} 2^{-n}(k_i+1)$, that is, between $\int \prod_{i\in J} g'_{in} d\mu$ and $\int \prod_{i\in J} g''_{in} d\mu$, where $g'_{in}(x) = 2^{-n}k$, $g''_{in}(x) = \min(1, 2^{-n}(k+1))$ when $2^{-n}k \leq g_i(x) < 2^{-n}(k+1)$. But this means that

$$\begin{aligned}|\phi_\Lambda(\langle E_i\rangle_{i\in J}) - \int \prod_{i\in J} g_i d\mu| &\leq \max(\int |\prod_{i\in J} g'_{in} - \prod_{i\in J} g_i| d\mu, \int |\prod_{i\in J} g''_{in} - \prod_{i\in J} g_i| d\mu)\\ &\leq \max(\int \sum_{i\in J} |g'_{in} - g_i| d\mu, \int \sum_{i\in J} |g''_{in} - g_i| d\mu)\end{aligned}$$

(because all the g_i, g'_{in}, g''_{in} take values in $[0,1]$, see 285O)

$$\leq 2^{-n}\#(J).$$

Since this is true for every $\Lambda \supseteq \Lambda_n$ and every $n \in \mathbb{N}$, $\lim_{\Lambda\uparrow} \phi_\Lambda(\langle E_i\rangle_{i\in J}) = \int \prod_{i\in J} g_i d\mu$. **Q**

(b) Accordingly the condition given exactly matches the definition in 458A.

458C All the fundamental theorems concerning stochastic independence have relativized forms. For the first we need a concept of 'relative probability distribution', as follows.

Definition Let (X, Σ, μ) be a probability space, T a σ-subalgebra of subsets of X, and $f \in \mathcal{L}^0(\mu)$. Then a **relative distribution of f over** T will be a family $\langle \nu_x\rangle_{x\in X}$ of Radon probability measures on $\mathbb{R}$ such that $x \mapsto \nu_x(H) : X \to [0,1]$ is T-measurable and $\int_F \nu_x(H)\mu(dx) = \mu(F \cap f^{-1}[H])$ for every Borel set $H \subseteq \mathbb{R}$ and every $F \in \mathrm{T}$, that is, $x \mapsto \nu_x H$ is a conditional expectation of $\chi f^{-1}[H]$ on T.

458D Theorem Let (X, Σ, μ) be a probability space, T a σ-subalgebra of Σ, and $f \in \mathcal{L}^0(\mu)$. Then there is a relative distribution of f over T, which is essentially unique in the sense that if $\langle \nu_x\rangle_{x\in X}$ and $\langle \nu'_x\rangle_{x\in X}$ are two such families, then $\nu_x = \nu'_x$ for $\mu\restriction$T-almost every x.

proof (a) Write μ_0 for the restriction of μ to T, $\hat{\mu}$ for the completion of μ, $\hat{\Sigma}$ for the domain of $\hat{\mu}$, and $\mathcal{B}$ for the Borel σ-algebra of $\mathbb{R}$. Then the function $x \mapsto (x, f(x)) : \operatorname{dom} f \to X \times \mathbb{R}$ is $(\hat{\Sigma}, \mathrm{T}\widehat{\otimes}\mathcal{B})$-measurable, just because $F \cap f^{-1}[H] \in \hat{\Sigma}$ for every $F \in \mathrm{T}$ and $H \in \mathcal{B}$. So we have a probability measure λ on $X \times \mathbb{R}$ defined by setting $\lambda W = \mu\{x : (x, f(x)) \in W\}$ for every $W \in \mathrm{T}\widehat{\otimes}\mathcal{B}$. The marginal measure on $\mathbb{R}$ is tight (that is, inner regular with respect to the compact sets) just because it is a Borel probability measure (433Ca). By 452M, we have a family $\langle \lambda_x\rangle_{x\in X}$ of Radon probability measures on $\mathbb{R}$ such that $\lambda W = \int \lambda_x W^{-1}[\{x\}]\mu_0(dx)$ for every $W \in \mathrm{T}\widehat{\otimes}\mathcal{B}$.

(b) The functions $x \mapsto \lambda_x H$ need not be T-measurable. However, if we set

$$g_q(x) = \lambda_x(]-\infty, q])$$

for $q \in \mathbb{Q}$, then every g_q is μ_0-virtually measurable, so there is a μ_0-conegligible set G such that every $g_q\restriction G$ is T-measurable. By the Monotone Class Theorem (136B), the family

$$\{H : H \in \mathcal{B},\ x \mapsto \lambda_x H : G \to [0,1] \text{ is T-measurable}\}$$

is the whole of $\mathcal{B}$. So if we set $\nu_x = \lambda_x$ for $x \in G$, and take λ_x to be the point mass at 0 (for instance) for $x \in X \setminus G$, we shall have a relative distribution of f over T as defined in 458C.

(c) Now suppose that $\langle \nu'_x \rangle_{x\in X}$ is another relative distribution of f over T. Then for each $H \in \mathcal{B}$ we have $\int_F \nu_x H\mu(dx) = \int_F \nu'_x H\mu(dx)$ for every $F \in \mathrm{T}$, so that $\nu_x H = \nu'_x H$ for μ_0-almost every x. But this means that for μ_0-almost every x, we have $\nu_x H = \nu'_x H$ for every interval H with rational endpoints; and for such x we must have $\nu_x = \nu'_x$ (416Eb).

458E Now we can state and prove a result corresponding to 272G.

Theorem Let (X, Σ, μ) be a probability space, T a σ-subalgebra of Σ, and $\langle f_i \rangle_{i\in I}$ a family in $\mathcal{L}^0(\mu)$. For each $i \in I$, let $\langle \nu_{ix} \rangle_{x\in X}$ be a relative distribution of f_i over T, and $\tilde{f}_i : X \to \mathbb{R}$ an arbitrary extension of f_i to the whole of X. Then the following are equiveridical:

(i) $\langle f_i \rangle_{i\in I}$ is relatively independent over T;

(ii) for any Baire set $W \subseteq \mathbb{R}^I$ and any $F \in \mathrm{T}$,

$$\hat{\mu}(F \cap \boldsymbol{f}^{-1}[W]) = \int_F \lambda_x W\mu(dx),$$

where $\hat{\mu}$ is the completion of μ, $\boldsymbol{f}(x) = \langle \tilde{f}_i(x) \rangle_{i\in I}$ for $x \in X$, and λ_x is the product of $\langle \nu_{ix} \rangle_{i\in I}$ for each x.

proof (a) Note first that if $i \in I$ and $H \subseteq \mathbb{R}$ is a Borel set, then $\int_F \nu_{ix} H\mu(dx) = \hat{\mu}(F \cap f_i^{-1}[H])$ for every $F \in \mathrm{T}$, so $x \mapsto \nu_{ix} H$ is a conditional expectation of $\chi f_i^{-1}[H]$ on T.

Suppose that $\langle f_i \rangle_{i\in I}$ is relatively independent, and $F \in \mathrm{T}$. Let $\mathcal{C}$ be the family of subsets of $\mathbb{R}^I$ expressible in the form $C = \{z : z \in \mathbb{R}^I, z(i) \in H_i \text{ for every } i \in J\}$ where $J \subseteq I$ is finite and $H_i \subseteq \mathbb{R}$ is a Borel set for each $i \in J$. For such a set C,

$$\hat{\mu}(F \cap \boldsymbol{f}^{-1}[C]) = \hat{\mu}(F \cap \bigcap_{i\in J} \tilde{f}_i^{-1}[H_i]) = \int_F \prod_{i=0}^{n} \nu_{ix} H_i \mu(dx)$$

(interpreting an empty product as χX)

$$= \int_F \lambda_x C\mu(dx).$$

So

$$\mathcal{W} = \{W : W \subseteq \mathbb{R}^I, \mu(F \cap \boldsymbol{f}^{-1}[W]) = \textstyle\int \lambda_x W\mu(dx)\}$$

includes $\mathcal{C}$; since it is a Dynkin class, it contains every Baire subset of $\mathbb{R}^I$ (by the Monotone Class Theorem, 136B), and (ii) is true.

(b) Now suppose that (ii) is true. Let Σ_i be the σ-algebra defined by f_i for each i. If $J \subseteq I$ is finite and $E_i \in \Sigma_i$ for each $i \in J$, then there are Borel sets $H_i \subseteq \mathbb{R}$ such that $E_i \triangle f_i^{-1}[H_i]$ is negligible for each i, so that $x \mapsto \nu_{ix} H_i$ is a conditional expectation of χE_i on T. Now by the same equations as before, in the opposite direction,

$$\int_F \prod_{i\in J} \nu_{ix} H_i \mu(dx) = \int_F \lambda_x C\mu(dx)$$

(where $C = \{z : z(i) \in H_i \text{ for } i \in J\}$)

$$= \hat{\mu}(F \cap \boldsymbol{f}^{-1}[C]) = \hat{\mu}(F \cap \bigcap_{i\in J} f_i^{-1}[H_i]) = \hat{\mu}(F \cap \bigcap_{i\in J} E_i)$$

for every $F \in \mathrm{T}$. As $\langle E_i \rangle_{i\in J}$ is arbitrary, $\langle \Sigma_i \rangle_{i\in I}$ and $\langle f_i \rangle_{i\in I}$ are relatively independent.

Remarks Of course the ungainly shift to $\tilde{f}_i$ is unnecessary if I is countable; but for uncountable I the intersection $\bigcap_{i\in I} \operatorname{dom} f_i$, which is the only suitable domain for $\boldsymbol{f}$, may not be conegligible.

I said that λ_x should be 'the product of $\langle \nu_{ix} \rangle_{i\in I}$'. Since the ν_{ix} are Radon probability measures, we have two possible interpretations of this: either the 'ordinary' product measure of §254 or the 'quasi-Radon' product measure of §417. But as we are interested only in the values of $\lambda_x W$ for Baire sets W, it makes no difference which we choose.

458F Proposition (Compare 272K.) Let (X,Σ,μ) be a probability space, T a σ-subalgebra of Σ, and $\langle\Sigma_i\rangle_{i\in I}$ a family of σ-subalgebras of Σ which is relatively independent over T. Let $\langle I_j\rangle_{j\in J}$ be a partition of I, and for each $j\in J$ let $\tilde\Sigma_j$ be the σ-algebra generated by $\bigcup_{i\in I_j}\Sigma_i$. Then $\langle\tilde\Sigma_j\rangle_{j\in J}$ is relatively independent over T.

proof For each $E\in\Sigma$ let g_E be a conditional expectation of χE on T. Take any finite $K\subseteq J$, and let $\boldsymbol{W}$ be the set of families $\langle W_j\rangle_{j\in K}$ such that $W_j\in\tilde\Sigma_j$ for each $j\in K$ and $\mu(F\cap\bigcap_{j\in K}W_j)=\int_F\prod_{j\in K}f_{W_j}d\mu$ for every $F\in\mathrm{T}$. For each $j\in K$, let $\mathcal{C}_j$ be the family of sets expressible as $W=X\cap\bigcap_{i\in L}E_i$ where $L\subseteq I_j$ is finite and $E_i\in\Sigma_i$ for $i\in L$. Note that in this case

$$\mu(F\cap W)=\mu(F\cap\textstyle\bigcap_{i\in L}E_i)=\int\prod_{i\in L}f_{E_i}d\mu$$

for every $F\in\mathrm{T}$, so $f_W=_{\text{a.e.}}\prod_{i\in L}f_{E_i}$, taking the product to be χX if L is empty.

If $W_j\in\mathcal{C}_j$ for each $j\in K$, then $\langle W_j\rangle_{j\in J}\in\boldsymbol{W}$. **P** Express W_j as $X\cap\bigcap_{i\in L_j}E_i$ where $L_j\subseteq I_j$ is finite and $E_i\in\Sigma_i$ whenever $j\in K$ and $i\in L_j$. Then

$$\mu(F\cap\bigcap_{j\in K}W_j)=\mu(F\cap\bigcap_{i\in L}E_i)$$

(where $L=\bigcup_{j\in K}L_j$)

$$=\int_F\prod_{i\in L}f_{E_i}d\mu$$

(because $\langle\Sigma_i\rangle_{i\in I}$ is relatively independent)

$$=\int_F\prod_{j\in K}\prod_{i\in L_j}f_{E_i}d\mu=\int_F\prod_{j\in K}f_{W_i}d\mu$$

for every $F\in\mathrm{T}$. **Q**

Observe next that if we fix $k\in K$, and a family $\langle W_j\rangle_{j\in K\setminus\{k\}}$, then the set of those $W_k\in\tilde\Sigma_k$ such that $\langle W_j\rangle_{j\in K}\in\boldsymbol{W}$ is a Dynkin class, so if it includes $\mathcal{C}_k$ it must include the σ-algebra generated by $\mathcal{C}_k$, viz., $\tilde\Sigma_k$. Now an easy induction on n shows that if $\langle W_j\rangle_{j\in K}\in\prod_{j\in K}\tilde\Sigma_j$ and $\#(\{j:W_j\notin\mathcal{C}_j\})=n$, then $\langle W_j\rangle_{j\in K}\in\boldsymbol{W}$. Taking $n=\#(K)$ we see that $\prod_{j\in K}\tilde\Sigma_j\subseteq\boldsymbol{W}$.

As this is true for every finite $K\subseteq J$, $\langle\tilde\Sigma_j\rangle_{j\in J}$ is relatively independent over T, as claimed.

458G Example The simplest examples of relatively independent σ-algebras arise as follows. Let (X,Σ,μ) be a probability space, $\langle\mathrm{T}_i\rangle_{i\in I}$ an independent family of σ-subalgebras of Σ, as in 272Ab, and T a σ-subalgebra of Σ which is independent of the σ-algebra generated by $\bigcup_{i\in I}\mathrm{T}_i$. For each $i\in I$, let Σ_i be the σ-algebra generated by $\mathrm{T}\cup\mathrm{T}_i$. Then $\langle\Sigma_i\rangle_{i\in I}$ is relatively independent over T.

proof For $i\in I$, set $\Sigma_{i0}=\mathrm{T}_i$ and $\Sigma_{i1}=\mathrm{T}$. Then $\langle\Sigma_{i\epsilon}\rangle_{(i,\epsilon)\in I\times\{0,1\}}$ is relatively independent over T. **P** Let $J\subseteq I\times\{0,1\}$ be a non-empty finite set and $E_{i\epsilon}\in\Sigma_{i\epsilon}$ for each $(i,\epsilon)\in J$. Set $J_0=\{i:(i,0)\in J\}$, $J_1=\{i:(i,1)\in J\}$. Then $g_{i0}=\mu E_{i0}\chi X$ is a conditional expectation of χE_{i0} on T for each $i\in J_0$, and $g_{i1}=\chi E_{i1}$ is a conditional expectation of χE_{i1} on T for each $i\in J_1$. If $F\in\mathrm{T}$, then

$$\begin{aligned}\mu(F\cap\bigcap_{(i,\epsilon)\in J}E_{i\epsilon})&=\mu((F\cap\bigcap_{i\in J_1}E_{i\epsilon})\cap\bigcap_{i\in J_0}E_{i\epsilon})\\&=\mu(F\cap\bigcap_{i\in J_1}E_{i\epsilon})\cdot\prod_{i\in J_0}\mu E_{i\epsilon}\end{aligned}$$

(taking the product to be 1 if J_0 is empty)

$$=\int_F\prod_{(i,\epsilon)\in J}g_{i\epsilon}d\mu.$$

As F and $\langle E_{i\epsilon}\rangle_{(i,\epsilon)\in J}$ are arbitrary, $\langle\Sigma_{i\epsilon}\rangle_{(i,\epsilon)\in I\times\{0,1\}}$ is relatively independent over T. **Q**

Since each Σ_i is the σ-algebra generated by $\Sigma_{i0}\cup\Sigma_{i1}$, 458F tells us that $\langle\Sigma_i\rangle_{i\in I}$ is also relatively independent over T.

458H Measure algebras We can look at the same ideas in the context of measure algebras.

(a) Suppose that $(\mathfrak{A},\bar\mu)$ is a probability algebra, and that $\mathfrak{C}$ is a closed subalgebra of $\mathfrak{A}$. If $a\in\mathfrak{A}$, then we can say that $u\in L^\infty(\mathfrak{C})$ is the conditional expectation of χa on $\mathfrak{C}$ if $\int_c u=\bar\mu(c\cap a)$ for every $c\in\mathfrak{C}$ (365R). Now we can say that a family $\langle b_i\rangle_{i\in I}$ in $\mathfrak{A}$ is **relatively (stochastically) independent** over $\mathfrak{C}$ if $\bar\mu(c\cap\inf_{i\in J}b_i)=\int_c\prod_{i\in J}u_i$ whenever $J\subseteq I$ is a non-empty finite set and u_i is the conditional expectation of χb_i on $\mathfrak{C}$ for every $i\in J$; while a family $\langle\mathfrak{B}_i\rangle_{i\in I}$ of subalgebras of $\mathfrak{A}$ is **relatively (stochastically) independent over** $\mathfrak{C}$ if $\langle b_i\rangle_{i\in I}$ is relatively independent over $\mathfrak{C}$ whenever $b_i\in\mathfrak{B}_i$ for every $i\in I$.

Following 458F, we have the result that if $\langle\mathfrak{B}_i\rangle_{i\in I}$ is relatively independent over $\mathfrak{C}$, and $\langle I_j\rangle_{j\in J}$ is a partition of I, and $\tilde{\mathfrak{B}}_j$ is the closed subalgebra of $\mathfrak{A}$ generated by $\bigcup_{i\in I_j}\mathfrak{B}_i$ for every $j\in J$, then $\langle\tilde{\mathfrak{B}}_j\rangle_{j\in J}$ is relatively independent over $\mathfrak{C}$. The most natural proof, from where we are now standing, is to express $(\mathfrak{A},\bar\mu)$ as the measure algebra of a probability space (X,Σ,μ), set $\mathrm{T}=\{F:F^\bullet\in\mathfrak{C}\}$ and $\Sigma_i=\{E:E^\bullet\in\mathfrak{B}_i\}$ for each $i\in I$, and use 458F.)

(b) Note that if $a\in\mathfrak{A}$ and u is the conditional expectation of a on $\mathfrak{C}$, then $[\![u>0]\!]=\mathrm{upr}(a,\mathfrak{C})$, by 365Rc. So if $\langle\mathfrak{B}_i\rangle_{i\in I}$ is a family of subalgebras of $\mathfrak{A}$ which is relatively independent over $\mathfrak{C}$, and $J\subseteq I$ is finite, and $b_i\in\mathfrak{B}_i$ for each $i\in J$, then $\inf_{i\in J}b_i=0$ iff $\inf_{i\in J}\mathrm{upr}(b_i,\mathfrak{C})=0$. (If u_i is a conditional expectation of b_i on $\mathfrak{C}$ for each i, then

$$\inf_{i\in J}\mathrm{upr}(b_i,\mathfrak{C})=\inf_{i\in J}[\![u_i>0]\!]=[\![\textstyle\prod_{i\in J}u_i]\!]$$

is zero iff $\bar\mu(\inf_{i\in J}b_i)=\int\prod_{i\in J}u_i=0$.)

(c) We have a straightforward version of 458G, as follows. If $(\mathfrak{A},\bar\mu)$ is a probability algebra, $\langle\mathfrak{C}_i\rangle_{i\in I}$ is a (stochastically) independent family of closed subalgebras of $\mathfrak{A}$, $\mathfrak{C}$ is a closed subalgebra of $\mathfrak{A}$ independent of the algebra generated by $\bigcup_{i\in I}\mathfrak{C}_i$, and $\mathfrak{B}_i$ is the closed subalgebra of $\mathfrak{A}$ generated by $\mathfrak{C}\cup\mathfrak{C}_i$ for each i, then $\langle\mathfrak{B}_i\rangle_{i\in I}$ is relatively independent over $\mathfrak{C}$. (Either repeat the proof of 458G, looking at $\mathfrak{B}_{i0}=\mathfrak{C}_i$ and $\mathfrak{B}_{i1}=\mathfrak{C}$ for each i, or move to a measure space representing $\mathfrak{A}$ and quote 458G.)

458I Relative free products of probability algebras: Definition Let $\langle(\mathfrak{A}_i,\bar\mu_i)\rangle_{i\in I}$ be a family of probability algebras and $(\mathfrak{C},\bar\nu)$ a probability algebra, and suppose that we are given a measure-preserving Boolean homomomorphism $\pi_i:\mathfrak{C}\to\mathfrak{A}_i$ for each $i\in I$. A **relative free product** of $\langle(\mathfrak{A}_i,\bar\mu_i,\pi_i)\rangle_{i\in I}$ over $(\mathfrak{C},\bar\nu)$ is a probability algebra $(\mathfrak{A},\bar\mu)$, together with a measure-preserving Boolean homomorphism $\phi_i:\mathfrak{A}_i\to\mathfrak{A}$ for each $i\in I$, such that

$\phi_i\pi_i=\phi_j\pi_j:\mathfrak{C}\to\mathfrak{A}$ for all $i,j\in I$,
writing $\mathfrak{D}$ for the common value of the $\phi_i[\pi_i[\mathfrak{C}]]$, $\langle\phi_i[\mathfrak{A}_i]\rangle_{i\in I}$ is relatively independent over $\mathfrak{D}$,
$\mathfrak{A}$ is the closed subalgebra of itself generated by $\bigcup_{i\in I}\phi_i[\mathfrak{A}_i]$.

458J Theorem Let $\langle(\mathfrak{A}_i,\bar\mu_i)\rangle_{i\in I}$ be a family of probability algebras, $(\mathfrak{C},\bar\nu)$ a probability algebra and $\pi_i:\mathfrak{C}\to\mathfrak{A}_i$ a measure-preserving Boolean homomomorphism for each $i\in I$. Then $\langle(\mathfrak{A}_i,\bar\mu_i,\pi_i)\rangle_{i\in I}$ has an essentially unique relative free product over $(\mathfrak{C},\bar\nu)$.

proof (a)(i) Let $\mathfrak{B}$ be the free product of $\langle\mathfrak{A}_i\rangle_{i\in I}$ (315H); write $\varepsilon_i:\mathfrak{A}_i\to\mathfrak{B}$ for the canonical embedding of $\mathfrak{A}_i$ in $\mathfrak{B}$. For each $i\in I$, $a\in\mathfrak{A}$ we have a completely additive functional $c\mapsto\bar\mu_i(a\cap\pi_ic):\mathfrak{C}\to[0,1]$; let $u_{ia}\in L^\infty(\mathfrak{C})$ be a corresponding Radon-Nikodým derivative, so that $\int_c u_{ia}d\bar\nu=\bar\mu_i(a\cap\pi_ic)$ for every $c\in\mathfrak{C}$ (365E). By 326Q, there is a unique additive functional $\lambda:\mathfrak{B}\to[0,1]$ such that

$$\lambda(\inf_{i\in J}\varepsilon_ia_i)=\int\prod_{i\in J}u_{i,a_i}d\bar\nu$$

whenever $J\subseteq I$ is a non-empty finite set and $a_i\in\mathfrak{A}_i$ for every $i\in J$. Of course $u_{i1}=\chi1$ in $L^\infty(\mathfrak{C})$ for every $i\in I$, interpreting the '1' in u_{i1} in the Boolean algebra $\mathfrak{A}_i$, and the '1' in $\chi1$ in the Boolean algebra $\mathfrak{C}$; so (this time interpreting '1' in $\mathfrak{B}$) $\lambda1=1$ (the final '1' being a real number, of course). Note also that $u_{i,a\cap\pi_ic}=\chi c\times u_{ia}$ for every $c\in\mathfrak{C}$ and $a\in\mathfrak{A}_i$, because

$$\int_{c'}u_{i,a\cap\pi_ic}d\bar\nu=\bar\mu(a\cap\pi_ic\cap\pi_ic')=\int_{c\cap c'}u_{ia}d\bar\nu=\int_{c'}\chi c\times u_{ia}d\bar\nu$$

for every $c'\in\mathfrak{C}$.

(ii) By 393C, there are a probability algebra $(\mathfrak{A},\bar\mu)$ and a Boolean homomorphism $\phi:\mathfrak{B}\to\mathfrak{A}$ such that $\lambda=\bar\mu\phi$. We can of course suppose that $\mathfrak{A}$ is the order-closed subalgebra of itself generated by $\phi[\mathfrak{B}]$ (which is in fact automatically the case if we use the construction in the proof of 393C).

For each $i\in I$, set $\phi_i=\phi\varepsilon_i:\mathfrak{A}_i\to\mathfrak{A}$. It is a Boolean homomorphism because ϕ and ε_i are. If $a\in\mathfrak{A}_i$, then

$$\bar\mu\phi_i a=\lambda\varepsilon_i a=\int u_{ia}\,d\bar\nu=\bar\mu_i(a\cap\pi_i 1)=\bar\mu_i a,$$

so ϕ_i is measure-preserving.

If i, $j\in I$ and $c\in\mathfrak{C}$ then

$$\begin{aligned}\bar\mu(\phi_i\pi_i c\triangle\phi_j\pi_j c)&=\lambda(\varepsilon_i\pi_i c\triangle\varepsilon_j\pi_j c)\\&=\lambda(\varepsilon_i\pi_i c)+\lambda(\varepsilon_j\pi_j c)-2\lambda(\varepsilon_i\pi_i c\cap\varepsilon_j\pi_j c)\\&=\int u_{i,\pi_i c}\,d\bar\nu+\int u_{j,\pi_j c}\,d\bar\nu-2\int u_{i,\pi_i c}\times u_{j,\pi_j c}\,d\bar\nu\\&=\int\chi c\,d\bar\nu+\int\chi c\,d\bar\nu-2\int\chi c\times\chi c\,d\bar\nu=0.\end{aligned}$$

So $\phi_i\pi_i=\phi_j\pi_j$; write π for this common value. Set $\mathfrak{D}=\pi[\mathfrak{C}]$, so that π is a measure-preserving Boolean isomorphism between $\mathfrak{C}$ and $\mathfrak{D}$. Let $T:L^0(\mathfrak{C})\to L^0(\mathfrak{D})$ be the corresponding f-algebra isomorphism.

(iii) If $i\in I$ and $a\in\mathfrak{A}_i$, then Tu_{ia} is the conditional expectation of $\chi(\phi_i a)$ on $\mathfrak{D}$. **P** For any $d\in\mathfrak{D}$, set $c=\pi^{-1}d$; then

$$\begin{aligned}\bar\mu(d\cap\phi_i a)&=\bar\mu(\phi_i(\pi_i c\cap a))=\lambda(\varepsilon_i(\pi_i c\cap a))\\&=\int u_{a\cap\pi_i c}\,d\bar\nu=\int_c u_{ia}\,d\bar\nu=\int_d Tu_{ia}\end{aligned}$$

by 365H. **Q**

(iv) Suppose that $J\subseteq I$ is finite and not empty and that $d_i\in\phi_i[\mathfrak{A}_i]$ for each $i\in J$. For each $i\in I$ let $v_i\in L^\infty(\mathfrak{D})$ be the conditional expectation of χd_i on $\mathfrak{D}$, and let $a_i\in\mathfrak{A}_i$ be such that $\phi_i a=d_i$. Set $c=\pi^{-1}d$. Then

$$\begin{aligned}\bar\mu(d\cap\inf_{i\in J}d_i)&=\bar\mu(\inf_{i\in J}(d_i\cap d))=\lambda(\inf_{i\in J}\varepsilon_i(a_i\cap\pi_i c))\\&=\int\prod_{i\in J}u_{i,a_i\cap\pi_i c}\,d\bar\nu=\int_c\prod_{i\in J}u_{i,a_i}\,d\bar\nu\\&=\int_{\pi c}T(\prod_{i\in J}u_{i,a_i})\,d\bar\mu=\int_d\prod_{i\in J}Tu_{i,a_i}\,d\bar\mu=\int_d\prod_{i\in J}v_i\,d\bar\mu.\end{aligned}$$

As $\langle d_i\rangle_{i\in J}$ and d are arbitrary, $\langle\phi_i[\mathfrak{A}_i]\rangle_{i\in I}$ is relatively independent over $\mathfrak{D}$. This shows that $(\mathfrak{A},\bar\mu,\langle\phi_i\rangle_{i\in I})$ is a relative free product of $\langle(\mathfrak{A}_i,\bar\mu_i,\pi_i)\rangle_{i\in I}$ over $(\mathfrak{C},\bar\nu)$.

(b) Now suppose that $(\mathfrak{A}',\bar\mu',\langle\phi'_i\rangle_{i\in I})$ is another relative free product of $\langle(\mathfrak{A}_i,\bar\mu_i,\pi_i)\rangle_{i\in I}$ over $(\mathfrak{C},\bar\nu)$. Then we have a Boolean homomorphism $\psi:\mathfrak{B}\to\mathfrak{A}'$ such that $\phi'_i=\psi\varepsilon_i$ for every $i\in I$ (315I). In this case, $\bar\mu'\psi=\lambda$. **P** Let π' be the common value of $\phi'_i\pi_i$ for $i\in I$, set $\mathfrak{D}'=\pi[\mathfrak{C}]$, and let $T':L^0(\mathfrak{C})\to L^0(\mathfrak{D}')$ be the isomorphism corresponding to $\pi':\mathfrak{C}\to\mathfrak{D}$. If $a\in\mathfrak{A}$ and $c\in\mathfrak{C}$, then

$$\bar\mu'(\phi'_i a\cap\pi' c)=\bar\mu(a\cap\pi_c)=\int_c u_{ia}\,d\bar\nu=\int_{\pi' c}T'u_{ia}\,d\bar\mu'$$

by 365H (compare (a-iii) above); it follows that $T'u_{ia}$ is the conditional expectation of $\chi(\phi'_i a)$ on $\mathfrak{D}'$.

If $J\subseteq I$ is finite and not empty, and $a_i\in\mathfrak{A}_i$ for $i\in J$, then

$$\begin{aligned}\bar\mu'(\psi(\inf_{i\in J}\varepsilon_i a_i))&=\bar\mu'(\inf_{i\in J}\phi'_i a_i)=\int\prod_{i\in J}T'u_{i,a_i}\,d\bar\mu'\\&=\int T'(\prod_{i\in J}u_{i,a_i})\,d\bar\mu'=\int\prod_{i\in J}u_{i,a_i}\,d\bar\nu=\lambda(\inf_{i\in J}\varepsilon_i a_i).\end{aligned}$$

Because λ is the only additive functional on $\mathfrak{B}$ taking the right values on elements of this form, $\bar{\mu}'\psi = \lambda$. **Q**

In particular, $\psi b = 0$ whenever $b \in \mathfrak{B}$ and $\lambda b = 0$. It follows that $\psi b = \psi b'$ whenever b, $b' \in \mathfrak{B}$ and $\phi b = \phi b'$, since in this case $\lambda(b \triangle b') = \bar{\mu}(\phi b \triangle \phi b')$ is zero. So we have a function $\theta : \phi[\mathfrak{B}] \to \mathfrak{A}'$ defined by setting $\theta(\phi b) = \psi b$ for every $b \in \mathfrak{B}$, and of course θ is a Boolean homomorphism; moreover,

$$\bar{\mu}'\theta(\phi b) = \bar{\mu}'\psi b = \lambda b = \bar{\mu}\phi b$$

so θ is measure-preserving and an isometry for the measure metrics of $\mathfrak{A}$ and $\mathfrak{A}'$. If $i \in I$ and $a \in \mathfrak{A}$, then

$$\theta\phi_i a = \theta\phi\varepsilon_i a = \psi\varepsilon_i a = \phi' a,$$

so $\theta\phi_i = \phi'_i$ for every i. Because $\mathfrak{A}$ and $\mathfrak{A}'$ are the closed subalgebras generated by $\bigcup_{i\in I} \phi_i[\mathfrak{A}_i]$ and $\bigcup_{i\in I} \phi'_i[\mathfrak{A}_i]$ respectively, $\phi[\mathfrak{B}]$ and $\psi[\mathfrak{B}]$ are dense (323J). The isometry θ therefore extends uniquely to a measure algebra isomorphism $\hat{\theta} : \mathfrak{A} \to \mathfrak{A}'$ which must be the unique isomorphism such that $\hat{\theta}\phi_i = \phi'_i$ for every i. Thus $(\mathfrak{A}, \bar{\mu}, \langle\phi_i\rangle_{i\in I})$ and $(\mathfrak{A}', \bar{\mu}', \langle\phi'_i\rangle_{i\in I})$ are isomorphic, and the relative free product is essentially unique.

458K Developing the argument of the last part of the proof of 458J, we have the following.

Theorem Let $\langle(\mathfrak{A}_i, \bar{\mu}_i)\rangle_{i\in I}$, $\langle(\mathfrak{A}'_i, \bar{\mu}'_i)\rangle_{i\in I}$ be two families of probability algebras, and $\psi_i : \mathfrak{A}_i \to \mathfrak{A}'_i$ a measure-preserving Boolean homomorphism for each i. Let $(\mathfrak{C}, \bar{\nu})$, $(\mathfrak{C}', \bar{\nu}')$ be probability algebras and $\pi_i : \mathfrak{C} \to \mathfrak{A}_i$, $\pi'_i : \mathfrak{C}' \to \mathfrak{A}'_i$ measure-preserving Boolean homomomorphisms for each $i \in I$; suppose that we have a measure-preserving isomorphism $\psi : \mathfrak{C} \to \mathfrak{C}'$ such that $\pi'_i\psi = \psi_i\pi_i : \mathfrak{C} \to \mathfrak{A}'_i$ for each i. Let $(\mathfrak{A}, \bar{\mu}, \langle\phi_i\rangle_{i\in I})$ and $(\mathfrak{A}', \bar{\mu}', \langle\phi'_i\rangle_{i\in I})$ be relative free products of $\langle(\mathfrak{A}_i, \bar{\mu}_i, \pi_i)\rangle_{i\in I}$, $\langle(\mathfrak{A}'_i, \bar{\mu}'_i, \pi'_i)\rangle_{i\in I}$ over $(\mathfrak{C}, \bar{\nu})$, $(\mathfrak{C}', \bar{\nu}')$ respectively. Then there is a unique measure-preserving Boolean homomorphism $\hat{\psi} : \mathfrak{A} \to \mathfrak{A}'$ such that $\hat{\psi}\phi_i = \phi'_i\pi_i : \mathfrak{A}_i \to \mathfrak{A}'$ for every $i \in I$.

proof By the uniqueness assertion of 458J, we may suppose that $(\mathfrak{A}, \bar{\mu}, \langle\phi_i\rangle_{i\in I})$ has been constructed by the method in the proof of 458J.

(a) For $i \in A$, $a \in \mathfrak{A}$, $a' \in \mathfrak{A}'$ let $u_{ia} \in L^\infty(\mathfrak{C})$, $u'_{ia'} \in L^\infty(\mathfrak{C}')$ be defined as in the proof of 458J, so that

$$\int_c u_{ia}d\bar{\nu} = \bar{\mu}_i(a \cap \pi_i c), \quad \int_{c'} u'_{ia'}d\bar{\nu}' = \bar{\mu}'_i(a' \cap \pi'_i c')$$

whenever $c \in \mathfrak{C}$, $c' \in \mathfrak{C}'$. Let $T : L^0(\mathfrak{C}) \to L^0(\mathfrak{C}')$ be the sequentially order-continuous Riesz homomorphism such that $T(\chi c) = \chi(\psi c)$ for every $c \in \mathfrak{C}$ (364R). Now $u'_{i,\psi_i a} = Tu_{ia}$ whenever $i \in I$ and $a \in \mathfrak{A}_i$. **P** If $c \in \mathfrak{C}$, then

$$\int_{\psi c} Tu_{ia}d\bar{\nu}' = \int_c u_{ia}d\bar{\nu}$$

(365H)

$$= \bar{\mu}(a \cap \pi_i c) = \bar{\mu}'\psi_i(a \cap \pi_i c) = \bar{\mu}'(\psi_i a \cap \pi'_i\psi c) = \int_{\psi c} u_{i,\psi_i a}.$$

Because ψ is surjective, it follows that $Tu_{ia} = u_{i,\psi_i(a)}$. **Q**

(b) Let $\mathfrak{B}$ be the free product of $\langle\mathfrak{A}_i\rangle_{i\in I}$ $\varepsilon_i : \mathfrak{A}_i \to \mathfrak{B}$ the canonical embedding for each i; let λ be the functional on $\mathfrak{B}$ defined by the process of (a-i) in the proof of 458J. By 315I, there is a Boolean homomorphism $\theta : \mathfrak{B} \to \mathfrak{A}'$ such that $\theta\varepsilon_i = \phi'_i\psi_i : \mathfrak{A}_i \to \mathfrak{A}'$ for every i. Now $\bar{\mu}'\theta = \lambda$. **P** If $J \subseteq I$ is finite and $a_i \in \mathfrak{A}_i$ for every $i \in J$, then

$$\bar{\mu}'\theta(\inf_{i\in J} \varepsilon_i a_i) = \bar{\mu}'(\inf_{i\in J} \phi_i\psi_i a_i) = \int \prod_{i\in J} u'_{i,\psi_i a_i}d\bar{\nu}'$$

$$= \int \prod_{i\in J} Tu_{i,a_i}d\bar{\nu}' = \int T(\prod_{i\in J} u_{i,a_i})d\bar{\nu}'$$

(because $T\restriction L^\infty(\mathfrak{C})$ is multiplicative)

$$= \int \prod_{i\in J} u_{i,a_i})d\bar\nu = \lambda(\inf_{i\in J} \varepsilon_i a_i).$$

As λ, θ and $\bar\nu$ are all additive, $\lambda = \bar\nu\theta'$ (using 315Jb). **Q**

(c) Let $\phi : \mathfrak{B} \to \mathfrak{A}$ be the map described in (a-ii) of the proof of 458J. Then $\bar\mu(\phi b) = \lambda b = \bar\mu'(\theta b)$ for every $b \in \mathfrak{B}$; in particular,

$$\phi b = 0 \Rightarrow \bar\mu(\phi b) = 0 \Rightarrow \bar\mu'(\theta b) = 0 \Rightarrow \theta b = 0.$$

There is therefore a Boolean homomorphism $\tilde\theta : \phi[\mathfrak{B}] \to \mathfrak{A}'$ such that $\tilde\theta\phi = \theta$, and $\tilde\theta$ is measure-preserving on $\phi[\mathfrak{A}]$. Since $\phi[\mathfrak{B}]$ is topologically dense in $\mathfrak{A}$ (use 323H), $\tilde\theta$ has an extension to a measure-preserving Boolean homomorphism $\hat\psi : \mathfrak{A} \to \mathfrak{A}'$ (324O). Now, for $i \in I$ and $a \in \mathfrak{A}_i$,

$$\hat\psi\phi_i a = \hat\psi\phi\varepsilon_i a = \tilde\theta\phi\varepsilon_i a = \theta\varepsilon_i a = \phi_i'\psi_i a,$$

as required.

(d) To see that $\hat\psi$ is unique, we need observe only that the given formula defines in on the subalgebra $\phi[\mathfrak{B}]$ and that this is topologically dense in $\mathfrak{A}$, while $\hat\psi$, being measure-preserving, must be continuous.

458L Relative product measures: Definitions (a) Let $\langle X_i\rangle_{i\in I}$ be a family of sets, Y a set, and $\pi_i : X_i \to Y$ a function for each $i \in I$. The **fiber product** of $\langle (X_i, \pi_i)\rangle_{i\in I}$ is the set $\Delta = \{x : x \in \prod_{i\in I} X_i, \pi_i x(i) = \pi_j x(j) \text{ for all } i, j \in I\}$.

(b) Let $\langle (X_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a family of probability spaces and (Y, T, ν) a probability space, and suppose that we are given an inverse-measure-preserving function $\pi_i : X_i \to Y$ for each $i \in I$; let Δ be the fiber product of $\langle X_i, \pi_i\rangle_{i\in I}$. A **relative product measure** on Δ is a probability measure μ on Δ such that

(†) whenever $J \subseteq I$ is finite and not empty and $E_i \in \Sigma_i$ for $i \in J$, and g_i is a Radon-Nikodým derivative of the functional $F \mapsto \mu_i(E \cap \pi_i^{-1}[F]) : \mathrm{T} \to [0, 1]$ for each $i \in J$, then $\mu\{x : x \in \Delta, x(i) \in E_i \text{ for every } i \in J\}$ is defined and equal to $\int \prod_{i\in J} g_i d\nu$;

(‡) for every $W \in \Sigma$ there is a W' in the σ-algebra generated by $\{\{x : x \in \Delta, x(i) \in E\} : i \in I, E \in \Sigma_i\}$ such that $\mu(W \triangle W') = 0$.

Remark If μ is a relative product measure of $\langle (\mu_i, \pi_i)\rangle_{i\in I}$ over ν, then all the functions $x \mapsto x(i) : \Delta \to X_i$ are inverse-measure-preserving. **P** The condition (†) tells us that if $E \in \Sigma_i$ and g is any Radon-Nikodým derivative of $F \mapsto \mu_i(E \cap \pi_i^{-1}[F])$, then

$$\mu\{x : x(i) \in E\} = \int g\, d\nu = \mu_i E. \ \mathbf{Q}$$

It follows that if I is not empty then we have an inverse-measure-preserving function $\pi : \Delta \to Y$ defined by setting $\pi x = \pi_i x(i)$ whenever $x \in \Delta$ and $i \in I$.

Note that when verifying (†) we need check the equality $\mu\{x : x \in \Delta, x(i) \in E_i \text{ for every } i \in J\} = \int \prod_{i\in J} g_i d\nu$ for only one representative family $\langle g_i\rangle_{i\in J}$ of Radon-Nikodým derivatives for any given $\langle E_i\rangle_{i\in J}$.

458M Proposition Suppose that $\langle (X_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ is a family of probability spaces, (Y, T, ν) a probability space, $\pi_i : X_i \to Y$ an inverse-measure-preserving function for each $i \in I$, Δ the fiber product of $\langle X_i, \pi_i\rangle_{i\in I}$ and μ a relative product measure on Δ with domain Σ. Let $(\mathfrak{A}_i, \bar\mu_i)$, $(\mathfrak{C}, \bar\nu)$ and $(\mathfrak{A}, \bar\mu)$ be the measure algebras of (X_i, Σ_i, μ_i), (Y, T, ν) and (Δ, Σ, μ) respectively, and for $i \in I$ define $\bar\pi_i : \mathfrak{C} \to \mathfrak{A}_i$ and $\bar\phi_i : \mathfrak{A}_i \to \mathfrak{A}$ by setting $\bar\pi_i F^\bullet = \pi_i^{-1}[F]^\bullet$, $\bar\phi_i E^\bullet = \{x : x \in \Delta, x(i) \in E\}^\bullet$ for every $F \in \mathrm{T}$, $E \in \Sigma_i$. Then $(\mathfrak{A}, \bar\mu, \langle\bar\phi_i\rangle_{i\in I})$ is a relative free product of $\langle (\mathfrak{A}_i, \bar\mu_i, \bar\pi_i)\rangle_{i\in I}$ over $(\mathfrak{C}, \bar\nu)$.

proof The case $I = \emptyset$ is trivial (if you care to follow through the definitions to the letter, $\Delta = \prod_{i\in I} X_i = \{\emptyset\}$ and $\mathfrak{A}$ is the two-point algebra). So I will take it that I is not empty.

(a) Of course we have to check that all the $\bar\pi_i$ and $\bar\phi_i$ are measure-preserving Boolean homomorphisms between the appropriate algebras, but in view of the remark following the definition 458L, this is elementary. The condition that $\mathfrak{A}$ should be the closed subalgebra generated by $\bigcup_{i\in I} \bar\phi_i[\mathfrak{A}_i]$ is just a translation of the condition (‡).

(b) As I is not empty, we have a well-defined inverse-measure-preserving map $\pi : \Delta \to Y$ given by the formula $\pi(x) = \pi_i x(i)$ whenever $x \in \Delta$ and $i \in I$. Let $\bar{\pi} : \mathfrak{C} \to \mathfrak{A}$ be the corresponding measure-preserving homomorphism, so that $\bar{\pi} = \bar{\phi}_i \bar{\pi}_i$ for every i. Set $\mathfrak{D} = \bar{\pi}[\mathfrak{C}] \subseteq \mathfrak{A}$, and let $T : L^\infty(\mathfrak{C}) \to L^\infty(\mathfrak{D})$ be the f-algebra isomorphism corresponding to $\bar{\pi}$ (363F). For $i \in I$ and $E \in \Sigma_i$, set $u_{iE} = Tg^\bullet_{iE} \in L^\infty(\mathfrak{D})$. Then u_{iE} is the conditional expectation of $\chi\{x : x(i) \in E\}^\bullet$ on $\mathfrak{D}$. **P** If $d \in \mathfrak{D}$, it is of the form $\bar{\phi}_i \bar{\pi}_i F^\bullet$ where $F \in \mathrm{T}$, so that

$$\begin{aligned}\int_d u_{iE} d\bar{\mu} &= \int u_{iE} \times \chi d \, d\bar{\mu} = \int T(g^\bullet_{iE} \times \chi F^\bullet) d\bar{\mu} \\ &= \int g^\bullet_{iE} \times \chi F^\bullet d\bar{\nu} = \int_F g_{iE} d\nu \\ &= \mu_i(E \cap \pi_i^{-1}[F]) = \mu(\phi_i^{-1}[E] \cap \phi_i^{-1}[\pi_i^{-1}[F]]) = \bar{\mu}(d \cap \phi_i^{-1}[E]^\bullet).\end{aligned}$$

As d is arbitrary, we have the result. **Q**

(c) It follows that if $J \subseteq I$ is finite and not empty, and $a_i \in \bar{\phi}_i[\mathfrak{A}_i]$ and v_i is the conditional expectation of χa_i on $\mathfrak{D}$ for each $i \in J$, then $\bar{\mu}(\inf_{i \in J} a_i) = \int \prod_{i \in J} v_i d\bar{\mu}$. **P** Express a_i as $\phi_i^{-1}[E_i]^\bullet$, where $E_i \in \Sigma_i$, so that $v_i = u_{i,E_i}$ for each i. Then

$$\begin{aligned}\int \prod_{i \in J} v_i d\bar{\mu} &= \int \prod_{i \in J} Tg^\bullet_{i,E_i} d\bar{\mu} = \int T(\prod_{i \in J} g^\bullet_{i,E_i}) d\bar{\mu} = \int \prod_{i \in J} g^\bullet_{i,E_i} d\bar{\nu} \\ &= \int \prod_{i \in J} g_{i,E_i} d\nu = \mu(\bigcap_{i \in J} \phi_i^{-1}[E_i]) = \bar{\mu}(\inf_{i \in J} a_i). \ \mathbf{Q}\end{aligned}$$

But this is exactly what we need to know to see that $\langle \bar{\phi}_i[\mathfrak{A}_i] \rangle_{i \in I}$ is relatively independent over $\mathfrak{D}$, completing the proof that $(\mathfrak{A}, \bar{\mu}, \langle \bar{\phi}_i \rangle_{i \in I})$ is a relative free product of $(\langle (\mathfrak{A}_i, \bar{\mu}_i, \bar{\pi}_i) \rangle_{i \in I}$ over $\mathfrak{C}, \bar{\nu})$.

458N There is no general result on relative product measures to match 458J (see 458Xg, 458Xh). The general question of when we can expect relative product measures to exist seems interesting. Here I give a couple of sample results.

Proposition Let $\langle (X_i, \Sigma_i, \mu_i) \rangle_{i \in I}$ be a family of probability spaces, (Y, T, ν) a probability space, and $\pi_i : X_i \to Y$ an inverse-measure-preserving function for each i. Suppose that for each i we have a disintegration $\langle \mu_{iy} \rangle_{y \in Y}$ of μ_i such that $\mu^*_{iy} \pi_i^{-1}[\{y\}] = \mu_{iy} X_i = 1$ for every $y \in Y$. Let $\Delta \subseteq \prod_{i \in I} X_i$ be the fiber product of $\langle (X_i, \pi_i) \rangle_{i \in I}$, and Υ the subspace σ-algebra on Δ induced by $\widehat{\bigotimes}_{i \in I} \Sigma_i$. For $y \in Y$, let λ_y be the product of $\langle \mu_{iy} \rangle_{i \in I}$, $(\lambda_y)_\Delta$ the subspace measure on Δ and λ'_y its restriction to Υ. Then $\mu W = \int \lambda'_y W \nu(dy)$ is defined for every $W \in \Upsilon$, and μ is a relative product measure of $\langle (\mu_i, \pi_i) \rangle_{i \in I}$ over ν.

proof If $y \in Y$, then

$$\lambda'_y \Delta = \lambda^*_y \Delta == (\lambda_y)^* \textstyle\prod_{i \in I} \pi_i^{-1}[\{y\}] = 1$$

(254Lb). For $i \in I$ and $E \in \Sigma_i$ set $g_{iE}(y) = \mu_{iy} E$ when this is defined; then g_{iE} is a Radon-Nikodým derivative of $F \mapsto \mu_i(E \cap \pi_i^{-1}[F]) : \mathrm{T} \to [0,1]$ (452Qa). Write X for $\prod_{i \in I} X_i$; for $i \in I$ and $x \in X$ set $\phi_i(x) = x(i)$. If $J \subseteq I$ is finite and $E_i \in \Sigma_i$ for each $i \in J$, then

$$\begin{aligned}\int \lambda'_y(\Delta \cap \bigcap_{i \in J} \phi_i^{-1}[E_i]) \nu(dy) &= \int (\lambda_y)_\Delta(\Delta \cap \bigcap_{i \in J} \phi_i^{-1}[E_i]) \nu(dy) \\ &= \int \lambda_y(X \cap \bigcap_{i \in J} \phi_i^{-1}[E_i]) \nu(dy)\end{aligned}$$

(because $\lambda^*_y \Delta = 1$ and λ_y measures every $\phi_i^{-1}[E_i]$ for almost every y)

$$= \int \prod_{i \in J} \mu_{iy} E_i \nu(dy) = \int \prod_{i \in J} g_{i,E_i} d\nu.$$

In particular, $\int \lambda'_y(\Delta \cap \bigcap_{i\in J} \phi_i^{-1}[E_i])\nu(dy)$ is defined.

The set $\{W : W \subseteq X, \int \lambda'_y(W \cap \Delta)\nu(dy) \text{ is defined}\}$ is a Dynkin class of subsets of X containing $\bigcap_{i\in J} \phi_i^{-1}[E_i]$ whenever $J \subseteq I$ is finite and not empty and $E_i \in \Sigma_i$ for each $i \in J$; by the Monotone Class Theorem, it includes $\widehat{\bigotimes}_{i\in I}\Sigma_i$. So $\mu W = \int \lambda'_y W \nu(dy)$ is defined for every $W \in \Upsilon$. Moreover, the formula displayed above tells us that $\mu(\Delta \cap \bigcap_{i\in I} \phi_i^{-1}[E_i]) = \int \prod_{i\in J} g_{i,E_i} d\nu$ whenever $J \subseteq I$ is finite and $E_i \in \Sigma_i$ for each $i \in I$. Thus (†) of 458L is satisfied. And (‡) is true by the choice of Υ.

458O The latitude I have permitted in the definition of 'relative product' makes it possible to look for relative product measures with further properties, as in the following.

Proposition Let $\langle (X_i, \mathfrak{T}_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a family of compact Radon probability spaces, $(Y, \mathfrak{S}, \mathrm{T}, \nu)$ a Radon probability space, and $\pi_i : X_i \to Y$ a continuous inverse-measure-preserving function for each i. Then $\langle (\mu_i, \pi_i)\rangle_{i\in I}$ has a relative product measure μ over ν which is a Radon measure for the topology on the fiber product of $\langle (X_i, \pi_i)\rangle_{i\in I}$ induced by the product topology on $\prod_{i\in I} X_i$.

proof (a) For each $i \in I$, $E \in \Sigma_i$ let g_{iE} be a Radon-Nikodým derivative of $F \mapsto \mu_i(E \cap \pi_i^{-1}[F]) : \mathrm{T} \to [0, 1]$. Let $\mathcal{C}$ be the family of subsets of $X = \prod_{i\in I} X_i$ expressible in the form $C = X \cap \bigcap_{i\in J} \phi_i^{-1}[E_i]$ where $J \subseteq I$ is finite and $E_i \in \Sigma_i$ for each $i \in J$, writing $\phi_i(x) = x(i)$ for $x \in X$, $i \in I$. Because the expression here is unique unless one of the E_i is empty or X_i, we have a functional $\lambda_0 : \mathcal{C} \to [0, 1]$ defined by setting

$$\lambda_0(\textstyle\bigcap_{i\in J} \phi_i^{-1}[E_i]) = \int \prod_{i\in J} g_{i,E_i} d\nu$$

whenever $J \subseteq I$ is finite and not empty and $E_i \in \Sigma_i$ for every $i \in I$. It is easy to check that λ_0 is additive in the sense of 454E so (because every μ_i is perfect, by 416Wa and 343K) it has an extension to a measure λ on X with domain $\widehat{\bigotimes}_{i\in I}\Sigma_i$. By 454A, with $\mathcal{K}$ the family of compact subsets of X, λ is inner regular with respect to the compact sets. By 416O, there is a Radon measure $\tilde\lambda$ on X extending λ.

(b) Let Δ be the fiber product of $\langle (X_i, \pi_i)\rangle_{i\in I}$. Now the point is that Δ is $\tilde\lambda$-conegligible. **P** Because every π_i is continuous, Δ is closed. **?** If it is not conegligible, then, because $\tilde\lambda$ is τ-additive, there must be a basic open set of non-zero measure disjoint from Δ; express such a set as $W = \prod_{i\in J} \phi_i^{-1}[G_i]$ where $J \subseteq I$ is finite and $G_i \subseteq X_i$ is open for each $i \in J$. Because $\tilde\lambda$ is inner regular with respect to the compact sets, there is a compact set $K \subseteq W$ such that $\tilde\lambda K > 0$; setting $K_i = \phi_i[K]$, $K_i \subseteq G_i$ is compact for each i and $W' = \prod_{i\in J} \phi_i^{-1}[K_i]$ is non-negligible. Now we have

$$0 < \tilde\lambda(\textstyle\prod_{i\in J} \phi_i^{-1}[K_i]) = \lambda_0(\prod_{i\in J} \phi_i^{-1}[K_i]) = \int \prod_{i\in J} g_{i,K_i} d\nu,$$

so $F = \{y : y \in Y, g_{i,K_i}(y) > 0 \text{ for every } i \in J\}$ is non-negligible. On the other hand, for each $i \in J$ we have

$$\textstyle\int_{Y\setminus\pi_i[K_i]} g_{i,K_i} d\nu = \mu_i(K_i \cap \pi_i^{-1}[Y \setminus K_i]) = 0$$

so that $F \setminus \pi_i[K_i]$ is negligible. Accordingly $\bigcap_{i\in J} \pi_i[K_i]$ is non-negligible, and must meet the support Y_0 of Y; let y be any point of the intersection. For $i \in J$, choose $x(i) \in K_i$ such that $\pi_i x(i) = y$. For $i \in I \setminus J$, $\pi_i[X_i]$ is a compact subset of Y, and $\nu\pi_i[X_i] = \mu_i\pi_i^{-1}[\pi_i[X_i]] = 1$, so $Y_0 \subseteq \pi_i[X_i]$ and we can therefore choose $x(i) \in X_i$ with $\pi_i x(i) = y$. This defines $x \in \Delta$. But as $x(i) \in K_i$ for $i \in J$, we also have

$$x \in \textstyle\bigcap_{i\in J} \phi_i^{-1}[K_i] \subseteq \bigcap_{i\in J} \phi_i^{-1}[G_i] \subseteq X \setminus \Delta,$$

which is impossible. **X**

Thus Δ is $\tilde\lambda$-conegligible, as claimed. **Q**

(c) Let μ be the subspace measure on Δ induced by $\tilde\lambda$, and Σ its domain, so that μ is a Radon probability measure on Δ with its subspace topology (416Rb). Concerning (†) of 458L, if $J \subseteq I$ is finite and not empty and $E_i \in \Sigma_i$ for $i \in J$, then

$$\mu(\textstyle\bigcap_{i\in J} \phi_i^{-1}[E_i]) = \tilde\lambda(\bigcap_{i\in J} \phi_i^{-1}[E_i]) = \lambda_0(\bigcap_{i\in J} \phi_i^{-1}[E_i]) = \int \prod_{i\in J} g_{i,E_i} d\nu,$$

as required. Finally, for (‡), the σ-algebra Υ generated by $\{\phi_i^{-1}[E] : i \in I, E \in \Sigma_i\}$ is just the subspace σ-algebra induced by $\widehat{\bigotimes}_{i\in I}\Sigma_i$. Let $\mathfrak{A}$ be the measure algebra of $\tilde\lambda$ and $\mathfrak{B} \subseteq \mathfrak{A}$ the set $\{W^\bullet : W \in \widehat{\bigotimes}_{i\in I}\Sigma_i\}$.

Then $\mathfrak{B}$ is a closed subalgebra of $\mathfrak{A}$. If $W \subseteq X$ is open, then for every $\epsilon > 0$ there is a $W_0 \in \widehat{\bigotimes}_{i\in I}\Sigma_i$ such that $W_0 \subseteq W$ and $\tilde{\lambda}(W \setminus W_0) \leq \epsilon$, so $W^\bullet \in \mathfrak{B}$; accordingly $\{W : W^\bullet \in \mathfrak{B}\}$ contains every open set and every Borel set and must be the whole of $\operatorname{dom}\lambda$. Returning to the measure μ, we see that if $W \in \Sigma$ there must be a $W_0 \in \widehat{\bigotimes}_{i\in I}\Sigma_i$ such that $\tilde{\lambda}(W \triangle W_0) = 0$; now $W_0 \cap \Delta \in \Upsilon$ and $\mu(W \triangle (W_0 \cap \Delta)) = 0$. So (‡) also is true, and we have a relative product measure of the declared type.

458P We can of course make a general search through theorems about product measures, looking for ways of re-presenting them as theorems about relative product measures. There is an associative law, for instance (458Xn). To give an idea of what is to be expected, I offer a result corresponding to 253D.

Proposition Let (X_1, Σ_1, μ_1), (X_2, Σ_2, μ_2) and (Y, T, ν) be probability spaces, and $\pi_1 : X_1 \to Y$, $\pi_2 : X_2 \to Y$ inverse-measure-preserving functions. Let Δ be the fiber product of (X_1, π_1) and (X_2, π_2), and suppose that μ is a relative product measure of (μ_1, π_1) and (μ_2, π_2) over ν; set $\pi x = \pi_1 x(1) = \pi_2 x(2)$ for $x \in \Delta$. Take $f_1 \in \mathcal{L}^1(\mu_1)$ and $f_2 \in \mathcal{L}^2(\mu_2)$, and set $(f_1 \otimes f_2)(x) = f_1(x(1))f_2(x(2))$ when $x \in \Delta \cap (\operatorname{dom} f_1 \times \operatorname{dom} f_2)$. For $i = 1, 2$ let $g_i \in \mathcal{L}^1(\nu)$ be a Radon-Nikodým derivative of $F \mapsto \int_{\pi_i^{-1}[F]} f_i d\mu_i : \mathrm{T} \to \mathbb{R}$. Then $\int_F g_1 \times g_2 d\nu = \int_{\pi^{-1}[F]} f_1 \otimes f_2 d\mu$ for every $F \in \mathrm{T}$.

proof When f_1 and f_2 are characteristic functions of measurable sets, this is just the definition of 'relative product measure'. The formula for g_i corresponds to a linear operator from $L^1(\mu_i)$ to $L^1(\nu)$, so the result is true for simple functions f_1 and f_2. If f_1 and f_2 are almost everywhere limits of non-decreasing sequences $\langle f_{1n}\rangle_{n\in\mathbb{N}}$, $\langle f_{2n}\rangle_{n\in\mathbb{N}}$ of non-negative simple functions, then the corresponding sequences $\langle g_{1n}\rangle_{n\in\mathbb{N}}$, $\langle g_{2n}\rangle_{n\in\mathbb{N}}$ will also be non-decreasing and non-negative and convergent to g_1, g_2 ν-a.e.; moreover, because $x \mapsto x(1)$ and $x \mapsto x(2)$ are inverse-measure-preserving, $f_1 \otimes f_2 = \lim_{n\to\infty} f_{1n} \otimes f_{2n}$ μ-a.e. So in this case we shall have

$$\begin{aligned}\int_{\pi^{-1}[F]} f_1 \otimes f_2 d\mu &= \lim_{n\to\infty} \int_{\pi^{-1}[F]} f_{1n} \otimes f_{2n} d\mu \\ &= \lim_{n\to\infty} \int_F g_{1n} \times g_{2n} d\nu = \int_F g_1 \times g_2 d\nu\end{aligned}$$

for every $F \in \mathrm{T}$. Finally, considering positive and negative parts, we can extend the result to general integrable f_1 and f_2.

458X Basic exercises >(a) Find an example of a probability space (X, Σ, μ) with σ-subalgebras Σ_1, Σ_2 and T of Σ such that Σ_1 and Σ_2 are independent but are not relatively independent over T.

(b) In 458C, show that (writing $\hat{\mu}$ for the completion of μ) $\hat{\mu}(F \cap f^{-1}[H]) = \int_F \nu_x H \mu(dx)$ for every $F \in \mathrm{T}$ and every universally measurable $H \subseteq \mathbb{R}$.

(c) Let (X, Σ, μ) be a probability space, $\langle \mathrm{T}_i\rangle_{i\in I}$ an independent family of σ-subalgebras of Σ, as in 272Ab, and T a σ-subalgebra of Σ which is independent of the σ-algebra generated by $\bigcup_{i\in I} \mathrm{T}_i$. For each $i \in I$, let T_i' be a σ-subalgebra of T, and Σ_i the σ-algebra generated by $\mathrm{T}_i' \cup \mathrm{T}_i$. Show that $\langle \Sigma_i\rangle_{i\in I}$ is relatively independent over T.

(d) In 458H, prove the result concerning the $\tilde{\mathfrak{B}}_j$ directly from 313G, without appealing to 458F.

(e) Let $\langle(\mathfrak{A}_i, \bar{\mu}_i)\rangle_{i\in I}$ be a family of probability algebras. Show that their probability algebra free product (325K) can be identified with their relative free product over $(\mathfrak{C}, \bar{\nu})$ if $\mathfrak{C}$ is the two-element Boolean algebra, $\bar{\nu}$ its unique probability measure, and $\pi_i : \mathfrak{C} \to \mathfrak{A}_i$ the trivial Boolean homomorphism for every i.

>(f) Let Y be a set, $\langle Z_i\rangle_{i\in I}$ a family of sets, and $\pi_i : Y \times Z_i \to Y$ the canonical map for each i. Show that the fiber product of $\langle(Y \times Z_i, \pi_i)\rangle_{i\in I}$ can be identified with $Y \times \prod_{i\in I} Z_i$.

(g) Let ν be Lebesgue measure on $[0, 1]$, and X_1, $X_2 \subseteq [0, 1]$ disjoint sets with outer measure 1. For each $i \in \{1, 2\}$ let μ_i be the subspace measure on X_i and $\pi_i : X_i \to [0, 1]$ the identity map. Show that (μ_1, π_1) and (μ_2, π_2) have no relative product measure over ν.

(h) Let ν be the usual measure on the split interval $I^{\|}$ (343J), and μ Lebesgue measure on $[0,1]$. Set $\pi_1(t) = t^+$, $\pi_2(t) = t^-$ for $t \in [0,1]$. Show that (μ, π_1) and (μ, π_2) have no relative product measure over ν.

(i) Let ν be Lebesgue measure on $[0,1]$. For each $t \in [0,1]$, set $X_t = [0,1] \setminus \{t\}$; let μ_t be the subspace measure on X_t and $\pi_t : X_t \to [0,1]$ the identity map. Show that $\langle(\mu_t, \pi_t)\rangle_{t\in[0,1]}$ has no relative product measure over ν.

(j) Let (X, Σ, μ) be a probability space, T a σ-subalgebra of Σ, and $\langle\Sigma_i\rangle_{i\in I}$ a family of σ-subalgebras of Σ, all including T. Set $\pi_i(x) = x$ for every $x \in X$. Show that $\langle\Sigma_i\rangle_{i\in I}$ is relatively independent over T iff $\mu\restriction\Sigma^*$ is a relative product measure of $\langle(\mu\restriction\Sigma_i, \pi_i)\rangle_{i\in I}$ over $\mu\restriction\mathrm{T}$, where Σ^* is the σ-algebra generated by $\bigcup_{i\in I}\Sigma_i$.

(k) (i) Let $\langle(X_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a family of probability spaces and (X, Σ, μ) their ordinary probability space product. Show that μ is a relative product measure of $\langle(\mu_i, \pi_i)\rangle_{i\in I}$ over ν where Y is a singleton set, ν its unique probability measure, and $\pi_i : X_i \to Y$ the unique function for each i. (ii) Let $\langle(X_i, \mathfrak{T}_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a family of quasi-Radon probability spaces and $(X, \mathfrak{T}, \Sigma, \mu)$ their quasi-Radon probability space product. Show that μ is a relative product measure of $\langle\mu_i\rangle_{i\in I}$ in the same sense as in (i).

(l) Suppose that $\langle(X_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ is a family of probability spaces and (Y, T, ν) is a probability space, and that for each $i \in I$ we are given an inverse-measure-preserving function $\pi_i : X_i \to Y$. Write $\hat\mu_i$ and $\hat\nu$ for the completions of μ_i, ν respectively. Show that $\langle(\mu_i, \pi_i)\rangle_{i\in I}$ has a relative product measure over ν iff $\langle(\hat\mu_i, \pi_i)\rangle_{i\in I}$ has a relative product measure over $\hat\nu$.

(m) Let $\langle(X_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a family of probability spaces, (Y, T, ν) a probability space, and $\pi_i : X_i \to Y$ an inverse-measure-preserving function for each $i \in I$. Show that if $\langle(\mu_i, \pi_i)\rangle_{i\in I}$ has a relative product measure over ν, so does $\langle(\mu_i, \pi_i)\rangle_{i\in J}$ for any $J \subseteq I$.

(n) Let $\langle(X_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a family of probability spaces, (Y, T, ν) a probability space, and $\pi_i : X_i \to Y$ an inverse-measure-preserving function for each $i \in I$. Let $\langle J_k\rangle_{k\in K}$ be a partition of I into non-empty sets. For each $k \in K$, let Δ_k be the fiber product of $\langle(X_i, \pi_i)\rangle_{i\in J_k}$; suppose that $\tilde\mu_k$ is a relative product measure of $\langle(\mu_i, \pi_i)\rangle_{i\in J_k}$ and $\tilde\Sigma_k$ its domain. Define $\tilde\pi_k : \Delta_k \to Y$ by setting $\tilde\pi_k(x) = \pi_i x(i)$ whenever $x \in \Delta_k$ and $i \in J_k$, so that $\tilde\pi_k$ is inverse-measure-preserving. Suppose that μ is a relative product measure of $\langle(\tilde\mu_k, \tilde\pi_k)\rangle_{k\in K}$ over ν. Show that μ can be regarded as a relative product measure of $\langle(\mu_i, \pi_i)\rangle_{i\in I}$ over ν.

(o) Let $\langle(X_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ and $\langle(X'_i, \Sigma'_i, \mu'_i)\rangle_{i\in I}$ be two families of probability spaces, (Y, T, ν) and (Y', T', ν') probability spaces, and $\pi_i : X_i \to Y$, $\pi'_i : X'_i \to Y'$ inverse-measure-preserving functions for each i. Suppose that we have a measure space isomorphism $g : Y \to Y'$ and inverse-measure-preserving functions $f_i : X_i \to X'_i$, for $i \in I$, such that $g\pi_i = \pi'_i f_i$ for every i. Show that if there is a relative product measure of $\langle(\mu_i, \pi_i)\rangle_{i\in I}$ over ν, then there is a relative product measure of $\langle(\mu'_i, \pi'_i)\rangle_{i\in I}$ over ν'.

(p) Let $\langle(X_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a countable family of probability spaces, (Y, T, ν) a probability space, and $\pi_i : X_i \to Y$ an inverse-measure-preserving function for each i. Suppose that for each i we have a disintegration of μ_i over ν which is strongly consistent with π_i. Show that $\langle(\mu_i, \pi_i)\rangle_{i\in I}$ has a relative product measure over ν.

(q) Let (X, Σ, μ), (X', Σ', μ') and (Y, T, ν) be probability spaces. Suppose that $\pi : X \to Y$ and $\pi' : X' \to Y$ are inverse-measure-preserving functions, and that μ' has a disintegration $\langle\mu'_y\rangle_{y\in Y}$ over (Y, T, ν) which is strongly consistent with π'. Show that (μ, π) and (μ', π') have a relative product measure over ν. (*Hint*: set $\lambda W = \int \mu'_{\pi x} W[\{x\}]\mu(dx)$ for every $W \in \Sigma\widehat{\otimes}\Sigma'$.)

>(r) Let Y be a Hausdorff space, $\langle Z_i\rangle_{i\in I}$ a family of Hausdorff spaces, μ_i a Radon probability measure on $Z_i \times Y$ and $\pi_i : Y \times Z_i \to Y$ the canonical map for each i. Suppose that all the image measures $\mu_i\pi_i^{-1}$ on Y are the same, and that all but countably many of the Z_i are compact. Show that there is a Radon probability measure μ on $Y \times \prod_{i\in I} Z_i$ such that $\mu_i = \mu\phi_i^{-1}$ for each i, where $\phi_i(y, z) = (y, z(i))$ for $y \in Y$, $z \in \prod_{j\in I} Z_j$.

(s) Let $\langle (X_i, \mathfrak{T}_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a countable family of Radon probability spaces, $(Y, \mathfrak{S}, \mathrm{T}, \nu)$ a Radon probability space, and $\pi_i : X_i \to Y$ an almost continuous inverse-measure-preserving function for each i. Show that $\langle (\mu_i, \pi_i)\rangle_{i\in I}$ has a relative product measure over ν which is a Radon measure for the topology on the fiber product of $\langle (X_i, \pi_i)\rangle_{i\in I}$ induced by the product topology on $\prod_{i\in I} X_i$.

(t) Let (X, Σ, μ) be a probability space and T a σ-subalgbra of Σ. Let f_1, f_2 be μ-integrable real-valued functions which are relatively independent over T, and suppose that $f_1 \times f_2$ is integrable. Let g_1, g_2 be conditional expectations of f_1, f_2 on T. Show that $g_1 \times g_2$ is a conditional expectation of $f_1 \times f_2$ on T. (*Hint*: 458P.)

458Y Further exercises (a) Let (X, Σ, μ) be a complete probability space, T a σ-algebra of subsets of Σ, and $\langle f_i\rangle_{i\in I}$ a family in $\mathcal{L}^0(\mu)$ which is relatively independent over T. Show that there is a family $\langle \nu_x\rangle_{x\in X}$ of countably compact quasi-Radon probability measures on $\mathbb{R}^I$ such that whenever $F \in \mathrm{T}$ and $J \subseteq I$ is countable and $H \subseteq \mathbb{R}^J$ is a Borel set, then

$$\mu\{x : x \in F \cap \textstyle\bigcap_{i\in J} \operatorname{dom} f_i,\ \langle f_i(x)\rangle_{i\in J} \in H\} = \int_F \nu_z\{x : x\restriction J \in H\}\mu(dz).$$

(b) Let (X, Σ, μ) be a probability space, T a σ-subalgebra of Σ, and $\langle \Sigma_n\rangle_{n\in\mathbb{N}}$ a sequence of σ-subalgebras of Σ which is relatively independent over T. For each $n \in \mathbb{N}$ let Σ_n^* be the σ-algebra generated by $\bigcup_{m\geq n} \Sigma_m$, and set $\Sigma_\infty = \bigcap_{n\in\mathbb{N}} \Sigma_n^*$. Show that for every $E \in \Sigma_\infty$ there is an $F \in \mathrm{T}$ such that $E \triangle F$ is negligible. (Compare 272O.)

(c) Let (X, Σ, μ) be a probability space, T a σ-subalgebra of Σ, and f, $g \in \mathcal{L}^0(\mu)$ relatively independent over T; suppose that $\langle \nu_x\rangle_{x\in X}$ and $\langle \nu'_x\rangle_{x\in X}$ are relative distributions of f and g over T. Show that $\langle \nu_x * \nu'_x\rangle_{x\in X}$ is a relative distribution of $f + g$ over T. (Compare 272S.)

(d) Let (X, Σ, μ) be a probability space, T a σ-subalgebra of Σ, and $\langle f_n\rangle_{n\in\mathbb{N}}$ a sequence in $\mathcal{L}^2(\mu)$ such that $\langle f_n\rangle_{n\in\mathbb{N}}$ is relatively independent over T and $\int_F f_n d\mu = 0$ for every $n \in \mathbb{N}$ and every $F \in \mathrm{T}$. (i) Suppose that $\langle \beta_n\rangle_{n\in\mathbb{N}}$ is a non-decreasing sequence in $]0, \infty[$, diverging to ∞, such that $\sum_{n=0}^\infty \frac{1}{\beta_n^2}\|f_n\|_2^2 < \infty$. Show that $\lim_{n\to\infty} \frac{1}{\beta_n}\sum_{i=0}^n f_i = 0$ a.e. (ii) Suppose that $\sup_{n\in\mathbb{N}} \|f_n\|_2 < \infty$. Show that $\lim_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^n f_i = 0$ a.e. (Compare 273D.)

(e) Let $\langle (X_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a family of measure spaces, (Y, T, ν) a measure space, and $\pi_i : X_i \to Y$ an inverse-measure-preserving function for each $i \in I$. For $i \in I$ and $E \in \Sigma_i$ let g_{iE} be a Radon-Nikodým derivative of the functional $F \mapsto \mu_i(E \cap \pi_i^{-1}[F])$. Let $\mathcal{C}$ be the family of subsets of $X = \prod_{i\in I} X_i$ of the form $X \cap \bigcap_{i\in J} \phi_i^{-1}[E_i]$ where $J \subseteq I$ is finite, $E_i \in \Sigma_i$ for $i \in J$ and $\phi_i(x) = x(i)$ for $x \in X$, $i \in I$. If $C = \bigcap_{i\in J} \phi_i^{-1}[E_i]$ where $J \subseteq I$ is finite and not empty and $E_i \in \Sigma_i$ for $i \in J$, set $\lambda_0 C = \int \prod_{i\in J} g_{i,E_i} d\nu$. Let $\Delta \subseteq X$ be the fiber product of $\langle (X_i, \pi_i)\rangle_{i\in I}$. Show that the following are equiveridical: (i) $\langle (\mu_i, \pi_i)\rangle_{i\in I}$ has a relative product measure over ν (ii) whenever $\langle C_n\rangle_{n\in\mathbb{N}}$ is a sequence in $\mathcal{C}$ covering Δ, $\sum_{n=0}^\infty \lambda_0 C_n \geq 1$ (iii) $\nu^*(\bigcap_{i\in I} \pi_i[X_i]) = 1$ and whenever T' is a countably generated σ-subalgebra of T, $J \subseteq I$ is countable, and Σ'_i is a countably generated σ-subalgebra of Σ_i including $\{\pi_i^{-1}[F] : F \in \mathrm{T}'\}$ for every $i \in J$, then $\langle (\mu_i\restriction\Sigma'_i, \pi_i)\rangle_{i\in J}$ has a relative product over $\nu\restriction\mathrm{T}'$.

(f) Let X be a Hausdorff space and P_{R} the set of Radon probability measures on X. For ν_1, $\nu_2 \in P_{\mathrm{R}}$, write $\mathrm{M}(\nu_1, \nu_2)$ for the set of Radon probability measures μ on $X \times X$ which have marginal measures ν_1 on the first copy of X, ν_2 on the second. (i) For a continuous pseudometric ρ on X, set $d_\rho(\nu_1, \nu_2) = \inf\{\int \rho(x, y)\mu(d(x, y)) : \mu \in \mathrm{M}(\nu_1, \nu_2)\}$. Show that d_ρ is a pseudometric on P_{R}. (ii) Show that if X is completely regular and P is a family of pseudometrics defining the topology of X, then $\{d_\rho : \rho \in \mathrm{P}\}$ defines the narrow topology of P_{R}. (Compare 274Ya, 437Yi.)

458 Notes and comments At a couple of points in Volume 3 (Dye's theorem, in §388, and Kawada's theorem, in §394) I took the trouble to generalize standard theorems to 'non-ergodic' forms. In both 388L and 394P the results are complicated by potentially non-trivial closed subalgebras of the probability algebra

we are studying. I remarked on both occasions that the generalization is only a matter of technique, but I do not suppose that it was obvious just why this must be so. It is however a fundamental theorem of the topic of 'random reals' in the theory of Forcing that *any* theorem about probability algebras must have a relativized form as a theorem about probability algebras with arbitrary closed subalgebras. The concept of 'relative Maharam type' from §333, for instance, is what matches 'Maharam type' for simple algebras; the concept of 'exchangeable' sequence is what matches 'independent identically distributed' sequence. (In probability theory, the keyword is 'mixture'.) In this section I present another example in the idea of 'relatively independent' closed subalgebras (458H). I should emphasize that the theory of random reals, when we eventually come to it in Volume 5, will not as a rule apply directly to measure spaces; it deals with measure algebras. But of course the ideas generated by this theory can often be profitably applied to constructions in measure spaces, and this is what I am seeking to do with relatively independent σ-algebras and relative product measures.

Just as independent σ-algebras are associated with product spaces (272J), relatively independent algebras are associated with relative products (458Xj). The archetype of a relative product measure is 458N; it is a kind of disintegrated product. It is frequently profitable to express the 'relative' concepts of measure theory in terms of disintegrations.

I introduce 'relative free products' of probability algebras before proceeding to measure spaces because the uniqueness property proved in 458J shows that we have an unambiguous definition. For measure spaces it seems for the moment better to leave ourselves a bit of freedom, not (for instance) favouring one product construction over another (458Xk). The requirement that a relative product measure be carried by the fiber product is seriously limiting (458Xg-458Xi, 458Ye), and forces us to seek strictly consistent disintegrations (458N), at least for uncountable products (see 458Xp). However, as we might hope, the special case of compact spaces with Radon measures and continuous functions is amenable to a different approach (458O); and we have a one-sided method for the product of two spaces (458Xq) which is reminiscent of 454C and 457F.

There are corresponding complications when we come to look at maps between different relative products. For measure algebras, we have a natural theorem (458K), based on the same algebraic considerations as the corresponding theorems in §§315 and 325; the only possibly surprising feature is the need to assume that $\psi : \mathfrak{C} \to \mathfrak{C}'$ is actually an isomorphism. For measure spaces there is a similar result (458Xo).

459 Symmetric measures and exchangeable random variables

Among the relatively independent families of random variables discussed in 458A-458E, it is natural to give extra attention to those which are 'relatively identically distributed'. It turns out that these have a particularly appealing characterization as the 'exchangeable' families (459C). In the same way, among the measures on a product space X^I there is a special place for those which are invariant under permutations of coordinates (459E, 459G).

459A The following elementary fact seems to have gone unmentioned so far.

Lemma Let (X, Σ, μ) and (Y, T, ν) be probability spaces and $f : X \to Y$ an inverse-measure-preserving function; set $\Sigma_0 = \{f^{-1}[F] : F \in \mathrm{T}\}$. Let T_1 be a σ-subalgebra of T and $\Sigma_1 = \{f^{-1}[F] : F \in \mathrm{T}_1\}$. If $g \in \mathcal{L}^1(\nu)$ and h is a conditional expectation of g on T_1, then hf is a conditional expectation of gf on Σ_1.

proof h is $\nu\restriction\mathrm{T}_1$-integrable and f is inverse-measure-preserving for $\mu\restriction\Sigma_1$ and $\nu\restriction\mathrm{T}_1$, so hf is $\mu\restriction\Sigma_1$-integrable. If $E \in \Sigma_1$ then there is an $F \in \mathrm{T}_1$ such that $E = f^{-1}[F]$, and now

$$\int_E gf\,d\mu = \int_{f^{-1}[F]} gf\,d\mu = \int_F g\,d\nu = \int_F h\,d\nu = \int_E hf\,d\mu.$$

As E is arbitrary, hf is a conditional expectation of hg on Σ_1.

459B Theorem Let (X, Σ, μ) be a probability space, Z a set, Υ a σ-algebra of subsets of Z and $\langle f_i \rangle_{i \in I}$ an infinite family of (Σ, Υ)-measurable functions from X to Z. For each $i \in I$, set $\Sigma_i = \{f_i^{-1}[H] : H \in \Upsilon\}$. Then the following are equiveridical:

(i) whenever $i_0, \ldots, i_r \in I$ are distinct, $j_0, \ldots, j_r \in I$ are distinct, and $H_k \in \Upsilon$ for each $k \leq r$, then $\mu(\bigcap_{k \leq r} f_{i_k}^{-1}[H_k]) = \mu(\bigcap_{k \leq r} f_{j_k}^{-1}[H_k])$;

(ii) there is a σ-subalgebra T of Σ such that

(α) $\langle \Sigma_i \rangle_{i \in I}$ is relatively independent over T,

(β) whenever $i, j \in I$, $H \in \Upsilon$ and $F \in \mathrm{T}$, then $\mu(F \cap f_i^{-1}[H]) = \mu(F \cap f_j^{-1}[H])$.

Moreover, if I is totally ordered by $\leq$, we can add

(iii) whenever $i_0 < \ldots < i_r \in I$, $j_0 < \ldots < j_r \in I$ and $H_k \in \Upsilon$ for each $k \leq r$, then $\mu(\bigcap_{k \leq r} f_{i_k}^{-1}[H_k]) = \mu(\bigcap_{k \leq r} f_{j_k}^{-1}[H_k])$.

proof (a) Since there is always some total ordering on I, we may assume that we have one from the start. Of course (i)⇒(iii). Also (ii)⇒(i). **P** Suppose that (ii) is true. Then (ii-β) tells us that for each $H \in \Upsilon$ there is a T-measurable function $g_H : X \to [0,1]$ which is a conditional expectation of $\chi(f_i^{-1}[H])$ on T for every $i \in I$. Now suppose that $i_0, \ldots, i_r \in I$ are distinct, $j_0, \ldots, j_r \in I$ are distinct, and $H_k \in \Upsilon$ for each $k \leq r$. Then

$$\mu(\textstyle\bigcap_{k \leq r} f_{i_k}^{-1}[H_k]) = \int (\prod_{k=0}^{r} g_{H_k}) d\mu = \mu(\bigcap_{k \leq r} f_{j_k}^{-1}[H_k])$$

because $\langle \Sigma_i \rangle_{i \in I}$ is relatively independent over T. So (i) is true. **Q**

So henceforth I will suppose that (iii) is true and seek to prove (ii).

(b) Suppose first that $I = \mathbb{N}$ with its usual ordering.

($\boldsymbol{\alpha}$) For each n, $r \in \mathbb{N}$, let Σ_{nr} be the σ-subalgebra of Σ generated by $\bigcup_{n \leq i \leq n+r} \Sigma_i$; let T_n be the σ-algebra generated by $\bigcup_{r \in \mathbb{N}} \Sigma_{nr}$, and $\mathrm{T} = \bigcap_{n \in \mathbb{N}} \mathrm{T}_n$. For $n \in \mathbb{N}$ and $H \in \Upsilon$, let $g_{nH} : X \to \mathbb{R}$ be a T-measurable function which is a conditional expectation of $\chi f_n^{-1}[H]$ on T.

($\boldsymbol{\beta}$) (The key.) For any $n \in \mathbb{N}$ and Borel set $H \subseteq \mathbb{R}$, g_{nH} is a conditional expectation of $\chi f_n^{-1}[H]$ on T_{n+1}. **P** For m, $r \in \mathbb{N}$, let $h_{mr} : X \to [0,1]$ be a Σ_{mr}-measurable function which is a conditional expectation of $\chi f_n^{-1}[H]$ on Σ_{mr}; for $m \in \mathbb{N}$, set $h_m = \lim_{r \to \infty} h_{mr}$ where this is defined. By Lévy's martingale theorem (275I) h_m is defined almost everywhere and is a conditional expectation of $\chi f_n^{-1}[H]$ on T_m.

For m, $r \in \mathbb{N}$, define $F_{mr} : X \to Z^{r+2}$ by setting $F_{mr}(x) = (f_n(x), f_m(x), f_{m+1}(x), \ldots, f_{m+r}(x))$ for $x \in X$. At this point, examine the hypothesis (iii). This implies that if $m > n$ and $r \in \mathbb{N}$ then

$$\begin{aligned}
\mu(F_{mr}^{-1}[H' \times H_0 \times \ldots \times H_r]) &= \mu(f_n^{-1}[H'] \cap \bigcap_{k \leq r} f_{m+k}^{-1}[H_k]) \\
&= \mu(f_n^{-1}[H'] \cap \bigcap_{k \leq r} f_{m+1+k}^{-1}[H_k]) \\
&= \mu(F_{m+1,r}^{-1}[H' \times H_0 \times \ldots \times H_r])
\end{aligned}$$

for all H', $H_0, \ldots, H_r \in \Upsilon$. By the Monotone Class Theorem (136C), the image measures μF_{mr}^{-1} and $\mu F_{m+1,r}^{-1}$ agree on the σ-algebra $\widehat{\bigotimes}_{r+2} \Upsilon$ of subsets of Z^{r+2} generated by measurable rectangles; set

$$\lambda = \mu F_{mr}^{-1} \restriction \widehat{\textstyle\bigotimes}_{r+2} \Upsilon = \mu F_{m+1,r}^{-1} \restriction \widehat{\textstyle\bigotimes}_{r+2} \Upsilon.$$

Let Λ be the σ-subalgebra of $\widehat{\bigotimes}_{r+2} \Upsilon$ generated by sets of the form $Z \times H_0 \times \ldots \times H_r$, and let h be a conditional expectation of $\chi(H \times Z^{r+1})$ on Λ with respect to λ. Then 459A tells us that hF_{mr} is a conditional expectation of $\chi(f_n^{-1}[H])$ on Σ_{mr}, and is therefore equal almost everywhere to h_{mr}. Similarly, $hF_{m+1,r} =_{\text{a.e.}} h_{m+1,r}$, and this is true for every $r \in \mathbb{N}$. But as F_{mr} and $F_{m+1,r}$ are both inverse-measure-preserving for μ and λ, this means that h_{mr}, h and $h_{m+1,r}$ all have the same distribution. In particular, $\int h_{mr}^2 d\mu = \int h_{m+1,r}^2 d\mu$. Now $\langle h_{mr} \rangle_{r \in \mathbb{N}}$ and $\langle h_{m+1,r} \rangle_{r \in \mathbb{N}}$ converge almost everywhere to h_m and h_{m+1} respectively, so

$$\textstyle\int h_m^2 d\mu = \lim_{r \to \infty} \int h_{mr}^2 d\mu = \lim_{r \to \infty} \int h_{m+1,r}^2 d\mu = \int h_{m+1}^2 d\mu.$$

On the other hand, h_{m+1} is a conditional expectation of h_m on T_{m+1} (233Eh). This means that

$$\int h_m \times h_{m+1} d\mu = \int h_{m+1} \times h_{m+1} d\mu$$

(233K). A direct calculation tells us that $\int (h_m - h_{m+1})^2 d\mu = 0$, so that $h_m =_{\text{a.e.}} h_{m+1}$. Inducing on r, we see that $h_m =_{\text{a.e.}} h_r$ whenever $n < m \leq r$.

Now the reverse martingale theorem (275K) tells us that $\lim_{m\to\infty} h_m$ is defined almost everywhere and is a conditional expectation of $\chi f_n^{-1}[H]$ on T, that is, is equal almost everywhere to g_{nH}. Since the h_m, for $m > n$, are equal almost everywhere, they are all equal to g_{nH} a.e. In particular, g_{nH} is equal a.e. to h_{n+1}, and is a conditional expectation of $\chi f_n^{-1}[H]$ on T_{n+1}. **Q**

(γ) If $n \in \mathbb{N}$ and $H_0, \ldots, H_r \in \Upsilon$, then $\prod_{i=0}^r g_{n+i,H_i}$ is a conditional expectation of $\chi(\bigcap_{i\leq r} f_{n+i}^{-1}[H_i])$ on T. **P** Induce on r. For $r = 0$ this is just the definition of g_{nH_0}. For the inductive step to $r \geq 1$, observe that $g_{nH_0} \times \prod_{i=1}^r \chi f_{n+i}^{-1}[H_i]$ is a conditional expectation of $\prod_{i=0}^r \chi f_{n+i}^{-1}[H_i]$ on T_{n+1}, by 233Eg or 233K, because g_{nH_0} is a conditional expectation of $\chi f_n^{-1}[H_0]$ on T_{n+1} and $\prod_{i=1}^r \chi f_{n+i}^{-1}[H_i]$ is T_{n+1}-measurable. But as (by the inductive hypothesis) $\prod_{i=1}^r g_{n+i,H_i}$ is a conditional expectation of $\prod_{i=1}^r \chi f_{n+i}^{-1}[H_i]$ on T, $\prod_{i=0}^r g_{n+i,H_i}$ is a conditional expectation of $\prod_{i=0}^r \chi f_{n+i}^{-1}[H_i]$ on T, by 233Eg/233K again. **Q**

(δ) In particular, $\prod_{i=0}^r g_{iH_i}$ is a conditional expectation of $\chi(\bigcap_{i\leq r} f_i^{-1}[H_i])$ on T for every $r \in \mathbb{N}$ and $H_0, \ldots, H_r \in \Upsilon$. This shows that $\langle \Sigma_n \rangle_{n\in\mathbb{N}}$ is relatively independent over T.

(ϵ) Now consider part (β) of the condition (ii). For this, observe that if $m > 0$, $H \in \Upsilon$ and $H_i \in \Upsilon$ for $i \leq r$, then

$$\mu(f_0^{-1}[H] \cap \textstyle\bigcap_{i\leq r} f_{m+i+1}^{-1}[H_i]) = \mu(f_m^{-1}[H] \cap \bigcap_{i\leq r} f_{m+i+1}^{-1}[H_i]).$$

By the Monotone Class Theorem,

$$\mu(F \cap f_0^{-1}[H]) = \mu(F \cap f_m^{-1}[H])$$

for any $F \in \mathrm{T}_{m+1}$ and in particular for any $F \in \mathrm{T}$. Thus (ii) is true.

(c) Now suppose that there is a strictly increasing sequence $\langle j_k \rangle_{k\in\mathbb{N}}$ in I. For each n, let T_n be the σ-algebra generated by $\bigcup_{k\geq n} \Sigma_{j_k}$, and set $\mathrm{T} = \bigcap_{n\in\mathbb{N}} \mathrm{T}_n$. Then (b), applied to $\langle f_{j_k} \rangle_{k\in\mathbb{N}}$, tells us that $\langle \Sigma_{j_k} \rangle_{k\in\mathbb{N}}$ is relatively independent over T and that for each $H \in \Upsilon$ there is a function g_H which is a conditional expectation of $\chi(f_{j_k}^{-1}[H])$ on T for every $k \in \mathbb{N}$.

(α) If $i_0, \ldots, i_r \in I$ are distinct and $H_0, \ldots, H_r \in \Upsilon$, then $\mu(\bigcap_{k\leq r} f_{i_k}^{-1}[H_k]) = \mu(\bigcap_{k\leq r} f_{j_k}^{-1}[H_k])$. **P** Let ρ be the permutation of $\{0, \ldots, r\}$ such that $i_{\rho(0)} < i_{\rho(1)} < \ldots < i_{\rho(r)}$. Then

$$\begin{aligned}\mu(\bigcap_{k\leq r} f_{i_k}^{-1}[H_k]) &= \mu(\bigcap_{k\leq r} f_{i_{\rho(k)}}^{-1}[H_{\rho(k)}]) = \mu(\bigcap_{k\leq r} f_{j_k}^{-1}[H_{\rho(k)}]) \\ &= \int (\prod_{k=0}^r g_{H_{\rho(k)}}) d\mu = \int (\prod_{k=0}^r g_{H_k}) d\mu = \mu(\bigcap_{k\leq r} f_{j_k}^{-1}[H_k]).\end{aligned}$$ **Q**

(β) Now suppose that $i_0, \ldots, i_r \in I$ are distinct. Then there is some $m \in \mathbb{N}$ such that $j_k \neq i_l$ for any $l \leq r$ and $k \geq m$. In this case, consider the sequence $f_{i_0}, \ldots, f_{i_r}, f_{j_m}, f_{j_{m+1}}, \ldots$. By ($\alpha$) here, this sequence satisfies the condition (iii). We can therefore apply the construction of (c). But observe that the tail σ-algebra obtained from $f_{i_0}, \ldots, f_{i_r}, f_{j_m}, \ldots$ is precisely T, as defined from $\langle f_{j_k} \rangle_{k\in\mathbb{N}}$ just above. So $\langle \Sigma_{i_k} \rangle_{k\leq r}$ is relatively independent over T. As $i_0, \ldots, i_r$ are arbitrary, $\langle \Sigma_i \rangle_{i\in I}$ is relatively independent over T. At the same time we see that if $H \in \Upsilon$ then all the $\chi(f_{i_k}^{-1}[H])$ have the same conditional expectations over T as $\chi(f_{j_m}^{-1}[H])$. So (ii-β) is satisfied.

(d) Finally, if there is no strictly increasing sequence in I, then $(I, \geq)$ is well-ordered; since I is infinite, the well-ordering starts with an initial segment of order type ω, that is, a sequence $\langle j_k \rangle_{k\in\mathbb{N}}$ such that $j_0 > j_1 > \ldots$. But note now that (iii) tells us that $\mu(\bigcap_{k\leq r} f_{i_k}^{-1}[H_k]) = \mu(\bigcap_{k\leq r} f_{j_k}^{-1}[H_k])$ whenever $i_0 > \ldots > i_r$ and $j_0 > \ldots > j_r$ and $H_k \in \Upsilon$ for every k. So we can apply (c) to $(I, \geq)$ to get the result in this case also.

459C Exchangeable random variables I spell out the leading special case of this theorem.

de Finetti's theorem Let (X, Σ, μ) be a probability space, and $\langle f_i \rangle_{i \in I}$ an infinite family in $\mathcal{L}^0(\mu)$. Then the following are equiveridical:

(i) the joint distribution of $(f_{i_0}, f_{i_1}, \ldots, f_{i_r})$ is the same as the joint distribution of $(f_{j_0}, f_{j_1}, \ldots, f_{j_r})$ whenever $i_0, \ldots, i_r \in I$ are distinct and $j_0, \ldots, j_r \in I$ are distinct;

(ii) there is a σ-subalgebra T of Σ such that $\langle f_i \rangle_{i \in I}$ is relatively independent over T and all the f_i have the same relative distributions over T.

Moreover, if I is totally ordered by $\leq$, we can add

(iii) the joint distribution of $(f_{i_0}, f_{i_1}, \ldots, f_{i_r})$ is the same as the joint distribution of $(f_{j_0}, f_{j_1}, \ldots, f_{j_r})$ whenever $i_0 < \ldots < i_r$ and $j_0 < \ldots < j_r$ in I.

Remark Families of random variables satisfying the condition in (i) are called **exchangeable**. The equivalence of (i) and (ii) can be expressed by saying that 'an exchangeable family of random variables is a mixture of independent identically distributed families'.

proof Changing each f_i on a negligible set will not change either their joint distributions (271De) or their relative distributions over T or their relative independence; so we may suppose that every f_i is a Σ-measurable function from X to $\mathbb{R}$. Now look at 459B, taking (Z, Υ) to be $\mathbb{R}$ with its Borel σ-algebra. The condition 459B(i) reads

whenever $i_0, \ldots, i_r \in I$ are distinct, $j_0, \ldots, j_r \in I$ are distinct, and $H_k \in \Upsilon$ for each $k \leq r$, then $\mu(\bigcap_{k \leq r} f_{i_k}^{-1}[H_k]) = \mu(\bigcap_{k \leq r} f_{j_k}^{-1}[H_k])$,

matching (i) here, by 271B; similarly, (iii) of 459B matches (iii) here. Equally, condition (ii) here is just a re-phrasing of 459B(ii) in the language of 458A. So 459B gives the result.

459D Specializing 459B in another direction, we have the case in which X is actually the product Z^I. In this case, the condition 459B(i) corresponds to a strong kind of symmetry in the measure μ. It now makes sense to look for subsets of $X = Z^I$ which are essentially invariant under permutations, and we have the following result.

Proposition Let Z be a set, Υ a σ-algebra of subsets of Z, I an infinite set and μ a measure on Z^I with domain the σ-algebra $\widehat{\bigotimes}_I \Upsilon$ generated by $\{\pi_i^{-1}[H] : i \in I, H \in \Upsilon\}$, taking $\pi_i(x) = x(i)$ for $x \in Z^I$ and $i \in I$. For each permutation ρ of I, define $\hat{\rho} : Z^I \to Z^I$ by setting $\hat{\rho}(x) = x\rho$ for $x \in Z^I$. Suppose that $\mu = \mu\hat{\rho}^{-1}$ for every ρ. Let $\mathcal{E}$ be the family of those sets $E \in \widehat{\bigotimes}_I \Upsilon$ such that $\mu(E \triangle \hat{\rho}^{-1}[E]) = 0$ for every permutation ρ of I, and $\mathcal{V}$ the family of those sets $E \in \widehat{\bigotimes}_I \Upsilon$ such that E is determined by coordinates in $I \setminus \{i\}$ for every $i \in I$.

(a) $\mathcal{E}$ is a σ-subalgebra of $\widehat{\bigotimes}_I \Upsilon$.

(b) $\mathcal{V}$ is a σ-subalgebra of $\mathcal{E}$.

(c) If $E \in \mathcal{E}$ and $J \subseteq I$ is infinite, then there is a $V \in \mathcal{V}$, determined by coordinates in J, such that $\mu(E \triangle V) = 0$.

(d) Setting $\Sigma_i = \{\pi_i^{-1}[H] : H \in \Upsilon\}$ for each $i \in I$,

(α) $\langle \Sigma_i \rangle_{i \in I}$ is relatively independent over $\mathcal{E}$,

(β) for every $H \in \Upsilon$ there is a $\mathcal{E}$-measurable function $g_H : Z^I \to [0,1]$ which is a conditional expectation of $\chi(\pi_i^{-1}[H])$ on $\mathcal{E}$ for every $i \in I$.

proof (a) is elementary.

(b) Let $V \in \mathcal{V}$. Suppose that $\rho : I \to I$ is a permutation, $i_0, \ldots, i_r \in I$ are distinct and $H_k \in \Upsilon$ for every $k \leq r$. Then there is a permutation $\sigma : I \to I$ such that $\sigma(i_k) = \rho(i_k)$ for every $k \leq r$ and $J = \{i : \sigma(i) \neq i\}$ is finite. By 254Ta, V is determined by coordinates in $I \setminus J$, so $\hat{\sigma}^{-1}[V] = V$. Set $j_k = \rho^{-1}(i_k)$ for each $k \leq r$. Now

$$\begin{aligned}\mu(\hat{\rho}^{-1}[V] \cap \bigcap_{k \leq r} \pi_{i_k}^{-1}[H_k]) &= \mu(V \cap \bigcap_{k \leq r} \pi_{j_k}^{-1}[H_k]) \\ &= \mu(\hat{\sigma}^{-1}[V] \cap \bigcap_{k \leq r} \pi_{i_k}^{-1}[H_k]) = \mu(V \cap \bigcap_{k \leq r} \pi_{i_k}^{-1}[H_k]).\end{aligned}$$

By the Monotone Class Theorem, as usual, $\mu(E \cap \hat{\rho}^{-1}[V]) = \mu(E \cap V)$ for every $E \in \widehat{\bigotimes}_I \Upsilon$. In particular, taking $E = V$ and $E = Z^I \setminus V$, we see that $V \triangle \hat{\rho}^{-1}[V]$ is negligible. As ρ is arbitrary, $V \in \mathcal{E}$.

This shows that $\mathcal{V} \subseteq \mathcal{E}$. Of course $\mathcal{V}$ is a σ-algebra, since it is just the intersection of the σ-algebras $\{V : V \in \widehat{\bigotimes}_I \Sigma, V \text{ is determined by coordinates in } I \setminus \{i\}\}$.

(c) For each $n \in \mathbb{N}$, there is a set $E_n \in \widehat{\bigotimes}_I \Sigma$, determined by a finite set J_n of coordinates, such that $\mu(E \triangle E_n) \leq 2^{-n}$. Choose permutations ρ_n of I such that $\langle \rho_n[J_n] \rangle_{n \in \mathbb{N}}$ is a disjoint sequence of subsets of J. Set $F_n = \hat{\rho}_n^{-1}[E_n]$; then F_n is determined by coordinates in $\rho_n[J_n]$ for each $n \in \mathbb{N}$, so $V = \bigcap_{n \in \mathbb{N}} \bigcup_{m \geq n} F_m$ belongs to $\mathcal{V}$ and is determined by coordinates in J. Also

$$\mu(E \triangle F_n) = \mu(\hat{\rho}[E] \triangle E_n) = \mu(E \triangle E_n) \leq 2^{-n}$$

for each n, so $\mu(E \triangle V) = 0$, as required.

(d) Let $\langle j_n \rangle_{n \in \mathbb{N}}$ be any sequence of distinct points of I. Set $J = \{j_n : n \in \mathbb{N}\}$. For $n \in \mathbb{N}$ let T_n be the σ-algebra generated by $\bigcup_{k \geq n} \Sigma_{j_k}$, and set $\mathrm{T} = \bigcap_{n \in \mathbb{N}} \mathrm{T}_n$, so that $\mathrm{T} = \{V : V \in \mathcal{V}, V \text{ is determined by coordinates in } J\}$. **P** Of course $\mathrm{T} \subseteq \mathcal{V}$ and every member of T is determined by coordinates in J, because every member of T_0 is. On the other hand, if $V \in \mathcal{V}$ is determined by coordinates in J, then fix some $w \in Z^{I \setminus J}$. In this case, identifying Z^I with $Z^J \times Z^{I \setminus J}$, the set $V_1 = \{z : z \in Z^J, (z, w) \in V\}$ must belong to $\widehat{\bigotimes}_J \Upsilon$, so $V = V_1 \times Z^{I \setminus J}$ belongs to T_0. Applying the same idea to $J \setminus \{j_k : k < n\}$, we see that $V \in \mathrm{T}_n$ for every n, so that $V \in \mathrm{T}$. **Q**

Part (c) of the proof of 459B tells us that $\langle \Sigma_i \rangle_{i \in I}$ is relatively independent over T and that for every $H \in \Upsilon$ there is a T-measurable g_H which is a conditional expectation of $\chi(\pi_i^{-1}[H])$ on T for every $i \in I$. Now (c) here tells us that g_H is a conditional expectation of $\chi(\pi_i^{-1}[H])$ on $\mathcal{E}$; and examining the definition in 458Aa, we see that $\langle \Sigma_i \rangle_{i \in I}$ is relatively independent over $\mathcal{E}$, as claimed.

459E If μ is countably compact, we have a strong disintegration theorem, as follows.

Theorem Let Z be a set, Υ a σ-algebra of subsets of Z, I an infinite set, and μ a countably compact probability measure on Z^I with domain the σ-algebra $\widehat{\bigotimes}_I \Upsilon$ generated by $\{\pi_i^{-1}[H] : i \in I, H \in \Upsilon\}$, taking $\pi_i(x) = x(i)$ for $x \in Z^I$ and $i \in I$. Then the following are equiveridical:

(i) for every permutation ρ of I, $x \mapsto x\rho : Z^I \to Z^I$ is inverse-measure-preserving for μ;

(ii) for every transposition ρ of two elements of I, $x \mapsto x\rho : Z^I \to Z^I$ is inverse-measure-preserving for μ;

(iii) for each $n \in \mathbb{N}$ and any two injective functions $p, q : n \to I$ the maps $x \mapsto xp : Z^I \to Z^n$, $x \mapsto xq : Z^I \to Z^n$ induce the same measure on Z^n;

(iv) there are a probability space (Y, T, ν) and a family $\langle \lambda_y \rangle_{y \in Y}$ of probability measures on Z such that $\langle \lambda_y^I \rangle_{y \in Y}$ is a disintegration of μ over ν, writing λ_y^I for the product of copies of λ_y.

Moreover, if I is totally ordered, we can add

(v) for each $n \in \mathbb{N}$ and any two strictly increasing functions $p, q : n \to I$ the maps $x \mapsto xp : Z^I \to Z^n$, $x \mapsto xq : Z^I \to Z^n$ induce the same measure on Z^n.

If the conditions (i)-(v) are satisfied, then there is a countably compact measure λ, with domain Υ, which is the common marginal measure of μ on every coordinate; and if $\mathcal{K}$ is a countably compact class of subsets of Z, closed under finite unions and countable intersections, such that λ is inner regular with respect to $\mathcal{K}$, then

(iv)′ there are a probability space (Y, T, ν) and a family $\langle \lambda_y \rangle_{y \in Y}$ of complete probability measures on Z, all with domains including $\mathcal{K}$ and inner regular with respect to $\mathcal{K}$, such that $\langle \lambda_y^I \rangle_{y \in Y}$ is a disintegration of μ over ν.

proof (a) Since any set I can be totally ordered, we may suppose from the outset that we have been given a total ordering $\leq$ on I. I start with the easy bits.

(iv)′⇒(iv) is trivial, at least if there is a common countably compact marginal measure on Z.

(iv)⇒(i) If (iv) is true and $\rho : I \to I$ is a permutation, take any $E \in \widehat{\bigotimes}_I \Sigma$ and set $E' = \{x : x \in Z^I, x\rho \in E\}$. For any $y \in Y$, $x \mapsto x\rho$ is an isomorphism of the measure space (Z^I, λ_y^I), so

$$\mu E' = \int \lambda_y^I E' \, \nu(dy) = \int \lambda_y^I E \, \nu(dy) = \mu E.$$

As E is arbitrary, (i) is true.

(i)⇒(ii) is trivial.

(ii)⇒(iii) There is a permutation ρ of I such that $q = \rho p$ and ρ moves only finitely many points of I, that is, ρ is a product of transpositions. By (ii), $x \mapsto x\rho$ and $x \mapsto x\rho^{-1}$ are inverse-measure-preserving for μ, that is, are isomorphisms of (Z^I, μ). But this means that $x \mapsto xp$ and $x \mapsto x\rho p = xq$ must induce the same measure on Z^n.

(iii)⇒(v) is trivial.

(b) So for the rest of the proof I assume that (v) is true. Taking $n = 1$ in the statement of (v), we see that there is a common image measure $\lambda = \mu\pi_i^{-1}$ for every $i \in I$. By 452R, λ is countably compact. Let $\mathcal{K} \subseteq \mathcal{P}Z$ be a countably compact class, closed under finite unions and countable intersections, such that λ is inner regular with respect to $\mathcal{K}$.

In 459B, set $X = Z^I$ and $\Sigma = \widehat{\bigotimes}_I \Upsilon$ and $f_i = \pi_i : X \to Z$ for $i \in I$. Then (v) here corresponds to (iii) of 459B, so (translating (ii) of 459B) we have a σ-subalgebra T of $\widehat{\bigotimes}_I \Upsilon$ and a family $\langle g_H \rangle_{H \in \Upsilon}$ of T-measurable functions from Z^I to $[0,1]$ such that

$$\mu(\textstyle\bigcap_{i \in J} \pi_i^{-1}[H_i]) = \int (\prod_{i \in J} g_{H_i}) d\mu$$

whenever $J \subseteq I$ is finite and not empty and $H_i \in \Upsilon$ for $i \in J$. In particular, g_H is a conditional expectation of $\chi(\pi_i^{-1}[H])$ on T whenever $H \in \Upsilon$ and $i \in I$.

Fix $i^* \in I$ for the moment. Set $\nu = \mu\restriction\mathrm{T}$. The inverse-measure-preserving function π_{i^*} from (X, μ) to (Z, λ) gives us an integral-preserving Riesz homomorphism $T_0 : L^\infty(\lambda) \to L^\infty(\mu)$ defined by setting $T_0 h^\bullet = (h\pi_{i^*})^\bullet$ for every $h \in \mathcal{L}^\infty(\lambda)$. Let $P : L^1(\mu) \to L^1(\nu)$ be the conditional expectation operator; then $T = PT_0 : L^\infty(\lambda) \to L^\infty(\nu)$ is an integral-preserving positive linear operator, and $T(\chi Z^\bullet) = \chi X^\bullet$.

By 452H, we have a family $\langle \lambda_x \rangle_{x \in X}$ of complete probability measures on Z, all with domains including $\mathcal{K}$ and inner regular with respect to $\mathcal{K}$, such that $\int_F h\pi_{i^*} d\mu = \int_F \int_Z h \, d\lambda_x \nu(dx)$ for every $h \in \mathcal{L}^\infty(\lambda)$ and $F \in \mathrm{T}$. In particular, setting $g'_H(x) = \lambda_x H$ whenever $H \in \Upsilon$ and $x \in X$ are such that $H \in \operatorname{dom} \lambda_x$, then g'_H will be a conditional expectation of $\chi\pi_{i^*}^{-1}[H]$ on T, and will be equal ν-almost everywhere to g_H.

This means that if $J \subseteq I$ is finite and not empty and $H_i \in \Upsilon$ for $i \in J$,

$$\begin{aligned}\int_X \lambda_x^I(\bigcap_{i \in J} \pi_i^{-1}[H_i]) \nu(dx) &= \int_X \prod_{i \in J} \lambda_x H_i \nu(dx) = \int_X \prod_{i \in J} g'_{H_i} d\nu \\ &= \int_X \prod_{i \in J} g_{H_i} d\nu = \int_X \prod_{i \in J} g_{H_i} d\mu = \mu(\bigcap_{i \in J} \pi_i^{-1}[H_i]).\end{aligned}$$

Thus the family $\mathcal{W}$ of sets $E \subseteq X$ such that $\int \lambda_x^I E \, \nu(dx)$ and μE are defined and equal contains all measurable cylinders. As $\mathcal{W}$ is a Dynkin class it includes $\widehat{\bigotimes}_I \Upsilon$. But this says exactly that $\langle \lambda_x^I \rangle_{x \in X}$ is a disintegration of μ over ν, as required by (iv)′.

Thus (v)⇒(iv)′ and the proof is complete.

459F Lemma Let X be a topological space, $\tilde{M}_\tau^+(X)$ the set of τ-additive totally finite topological measures on X and $\mu \in \tilde{M}_\tau^+(X)$ a measure which is inner regular with respect to the Borel sets. Let Y be a topological space, ν a totally finite τ-additive topological measure on Y and $\langle \mu_y \rangle_{y \in Y}$ a family of complete measures in $\tilde{M}_\tau^+(X)$ such that $y \mapsto \mu_y$ is continuous for the given topology on Y and the narrow topology on $\tilde{M}_\tau^+(X)$ (definition: 437Jd).

(a) Suppose that $\mathcal{U}$ is a base for the topology of X, closed under finite intersections and containing X, such that $\mu U = \int \mu_y U \, \nu(dy)$ for every $U \in \mathcal{U}$. Then $\langle \mu_y \rangle_{y \in Y}$ is a disintegration of μ over ν.

(b) Suppose that X is completely regular and that $\int u \, d\mu = \iint u \, d\mu_y \nu(dy)$ for every $u \in C_b(X)$. Then $\langle \mu_y \rangle_{y \in Y}$ is a disintegration of μ over ν.

proof (a) Let $\mathcal{E}$ be the family of those sets $E \subseteq X$ such that μE and $\int \mu_y E \, \nu(dy)$ are defined and equal. Then $\mathcal{E}$ is a Dynkin class including $\mathcal{U}$, so includes the σ-algebra generated by $\mathcal{U}$; in particular, it includes

$\mathcal{U}^* = \{U_0 \cup \ldots \cup U_n : U_0, \ldots, U_n \in \mathcal{U}\}$. For $A \subseteq X$, set $f_A(y) = \mu_y A$ whenever this is defined; note that if $G \subseteq X$ is open, then f_G is lower semi-continuous, being the composition of the continuous function $y \mapsto \mu_y$ and the semi-continuous function $\theta \mapsto \theta G$. If $H \subseteq X$ is open, set $\mathcal{G} = \{G : G \in \mathcal{U}^*, G \subseteq H\}$; then $\mathcal{G}$ is upwards-directed and has union H, so $f_H(y) = \sup_{G\in\mathcal{G}} f_G(y)$ for every $y \in Y$, because every μ_y is τ-additive. Accordingly

$$\int \mu_y H \, \nu(dy) = \int f_H d\nu = \sup_{G\in\mathcal{G}} \int f_G d\nu$$

(414Ba)

$$= \sup_{G\in\mathcal{G}} \mu G = \mu H,$$

and $H \in \mathcal{E}$.

Again using the Monotone Class Theorem, we see that every Borel set belongs to $\mathcal{E}$. Now if $E \in \operatorname{dom}\mu$, there are Borel sets E', E'' such that $E' \subseteq E \subseteq E''$ and $\mu E = \mu E' = \mu E''$, because μ is inner regular with respect to the Borel sets. Accordingly

$$\int f_{E'} d\nu = \mu E' = \mu E = \mu E'' = \int f_{E''} d\nu,$$

and $F = \{y : f_{E'}(y) = f_{E''}(y)\}$ is conegligible. But we are supposing that every μ_y is complete, so $\mu_y E$ is defined and equal to $\mu_y E'$ for every $y \in F$, and

$$\int \mu_y E \, \nu(dy) = \int \mu_y E' \, \nu(dy) = \mu E' = \mu E.$$

As E is arbitrary, $\langle \mu_y \rangle_{y\in Y}$ is a disintegration of μ over ν.

(b) In this case, the set $\mathcal{U}$ of cozero sets is a base for the topology of X closed under finite intersections. If $U \in \mathcal{U}$, there is a continuous $u : X \to \mathbb{R}$ such that $U = \{x : u(x) \neq 0\}$; setting $u_n = \chi X \wedge n|u|$ for $n \in \mathbb{N}$, $\langle u_n \rangle_{n\in\mathbb{N}}$ is a non-decreasing sequence in $C_b(X)$ with supremum χU, so

$$\begin{aligned}\mu U &= \sup_{n\in\mathbb{N}} \int u_n d\mu = \sup_{n\in\mathbb{N}} \iint u_n d\mu_y \nu(dy) \\ &= \iint (\sup_{n\in\mathbb{N}} u_n) d\mu_y \nu(dy) = \int \mu_y U \, \nu(dy).\end{aligned}$$

Thus the condition of (a) is satisfied and $\langle \mu_y \rangle_{y\in Y}$ is a disintegration of μ over ν.

459G Theorem Let Z be a Hausdorff space, I an infinite set, and $\tilde{\mu}$ a quasi-Radon probability measure on Z^I such that the marginal measures on each copy of Z are Radon measures. Write $P_{\mathrm{R}}(Z)$ for the set of Radon probability measures on Z with its narrow topology. Then the following are equiveridical:

(i) for every permutation ρ of I, $w \mapsto w\rho : Z^I \to Z^I$ is inverse-measure-preserving for $\tilde{\mu}$;

(ii) for every transposition ρ of two elements of I, $w \mapsto w\rho : Z^I \to Z^I$ is inverse-measure-preserving for $\tilde{\mu}$;

(iii) for each $n \in \mathbb{N}$ and any two injective functions $p, q : n \to I$ the maps $w \mapsto wp : Z^I \to Z^n$ and $w \mapsto wq : Z^I \to Z^n$ induce the same measure on Z^n;

(iv) there are a probability space (Y, T, ν) and a family $\langle \mu_y \rangle_{y\in Y}$ of τ-additive Borel probability measures on Z such that $\langle \tilde{\mu}_y^I \rangle_{y\in Y}$ is a disintegration of $\tilde{\mu}$ over ν, writing $\tilde{\mu}_y^I$ for the τ-additive product of copies of μ_y;

(v) there is a Radon probability measure $\tilde{\nu}$ on $P_{\mathrm{R}}(Z)$ such that $\langle \tilde{\theta}^I \rangle_{\theta\in P_{\mathrm{R}}(Z)}$ is disintegration of $\tilde{\mu}$ over $\tilde{\nu}$, writing $\tilde{\theta}^I$ for the quasi-Radon product of copies of θ.

Moreover, if I is totally ordered, we can add

(vi) for each $n \in \mathbb{N}$ and any two strictly increasing functions $p, q : n \to I$ the maps $w \mapsto wp : Z^I \to Z^n$ and $w \mapsto wq : Z^I \to Z^n$ induce the same measure on Z^n.

proof (a) As in 459E, we need consider only the case in which I is totally ordered, and the implications

$$\text{(v)} \Rightarrow \text{(iv)} \Rightarrow \text{(i)} \Rightarrow \text{(ii)} \Rightarrow \text{(iii)} \Rightarrow \text{(vi)}$$

are elementary. So henceforth I will suppose that (vi) is true and seek to prove (v).

(b) Write μ for $\tilde{\mu}\restriction\widehat{\bigotimes}_I\mathcal{B}(Z)$, where $\mathcal{B}(Z)$ is the Borel σ-algebra of Z. Then (vi) is also true of μ. (Strictly speaking, we ought to check that the different images of μ all have the same domain. But this is true, because the image of μ corresponding to a strictly increasing function $p : r \to I$ has domain $\widehat{\bigotimes}_r\mathcal{B}(Z)$.) The (unique) marginal measure λ of μ is the restriction to $\mathcal{B}(Z)$ of the Radon measure $\tilde{\lambda}$ which is the image of $\tilde{\mu}$, so is a tight Borel measure, therefore countably compact. By 454A, μ is countably compact. So 459E, with $\mathcal{K}$ the family of compact subsets of Z, tells us that there are a probability space (Y_0, T, ν_0) and a family $\langle\mu_y\rangle_{y\in Y_0}$ in $P_{\mathrm{R}}(Z)$ such that $\langle\mu_y^I\rangle_{y\in Y_0}$ is a disintegration of μ over ν_0, writing μ_y^I for the ordinary product of copies of μ_y. It follows that the family $\langle\tilde{\mu}_y^I\rangle_{y\in Y_0}$ of Radon product measures is a disintegration of μ over ν_0, just because $\tilde{\mu}_y^I$ extends μ_y^I. Note also that $\langle\mu_y\rangle_{y\in Y_0}$ is a disintegration of λ; this is clearly achieved by the proof of 459E, and it is necessarily true if $\langle\mu_y^I\rangle_{y\in Y_0}$ is to be a disintegration of μ. It follows that $\langle\mu_y\rangle_{y\in Y_0}$ is a disintegration of the completion $\tilde{\lambda}$ of λ over ν_0 (452B(a-ii)).

Let $\langle K_n\rangle_{n\in\mathbb{N}}$ be a disjoint sequence of compact subsets of Z such that $\sum_{n=0}^{\infty}\tilde{\lambda}K_n = 1$, and set $X_0 = \bigcup_{n\in\mathbb{N}}K_n$. Since

$$1 = \tilde{\lambda}X_0 = \lambda X_0 = \int_{Y_0}\mu_y(X_0)\nu_0(dy),$$

$\mu_y X_0 = 1$ for ν_0-almost every y, and $Y = \{y : y \in Y_0, \mu_y X_0 = 1\}$ is ν_0-conegligible. It follows that, writing ν for the subspace measure on Y, $\langle\tilde{\mu}_y^I\rangle_{y\in Y}$ is a disintegration of μ over ν, and $\langle\tilde{\mu}_y\rangle_{y\in Y}$ is a disintegration of $\tilde{\lambda}$ over ν.

(c) Give X_0 the disjoint union topology corresponding to the partition $\{K_n : n \in \mathbb{N}\}$, so that X_0 is σ-compact and locally compact; note that the identity map from X_0 to Z is continuous, and that the Borel σ-algebra $\mathcal{B}(X_0)$ is just $\{X_0 \cap E : E \in \mathcal{B}(Z)\}$. Consequently the subspace measure $\mu_y\restriction\mathcal{P}X_0$ induced on X_0 by μ_y is a Radon measure on X_0 for every $y \in Y$. Let $X = X_0 \cup \{x^*\}$ be the one-point compactification of X_0, and for $y \in Y$ let λ'_y be the Radon probability measure on X extending $\mu_y\restriction\mathcal{P}X_0$ (so that $\lambda'_y\{x^*\} = 0$). In the same way, let $\tilde{\lambda}'$ be the Radon probability measure on X extending $\tilde{\lambda}\restriction\mathcal{P}X_0$; of course $\tilde{\lambda}'X_0 = \tilde{\lambda}X_0 = 1$.

(d) Let ν_1 be the image measure on $P_{\mathrm{R}}(X)$ defined by setting $\nu_1 Q = \nu\{y : y \in Y, \lambda'_y \in Q\}$ whenever this is defined. Then ν_1 is a complete probability measure. For each $n \in \mathbb{N}$, K_n is an open-and-closed set in X, so $\theta \mapsto \theta K_n$ is continuous for the narrow topology on $P_{\mathrm{R}}(X)$, and

$$Q^* = \{\theta : \theta \in P_{\mathrm{R}}(X), \theta X_0 = 1\} = \{\theta : \theta \in P_{\mathrm{R}}(X), \textstyle\sum_{n=0}^{\infty}\theta K_n = 1\}$$

is a Baire set; of course $\nu_1 Q^* = 1$.

If $u \in C(X)$, then

$$\begin{aligned}\int_{P_{\mathrm{R}}(X)}\int_X u\,d\theta\,\nu_1(d\theta) &= \int_{Q^*}\int_X u\,d\theta\,\nu_1(d\theta)\\ &= \int_{Q^*}\int_{X_0} u\,d\theta\,\nu_1(d\theta) = \int_{P_{\mathrm{R}}(X)}\int_{X_0} u\,d\theta\,\nu_1(d\theta)\end{aligned}$$

is defined and equal to

$$\int_Y\int_{X_0} u\,d\mu_y\nu(dy) = \int_{X_0} u\,d\lambda$$

by 235L and 452F. In particular (because ν_1 is complete), $\theta \mapsto \int_X u\,d\theta$ is $\operatorname{dom}\nu_1$-measurable. So ν_1 measures every Baire subset of $P_{\mathrm{R}}(X)$. **P** Setting $\hat{u}(\theta) = \int_X u\,d\theta$ for $u \in C(X)$ and $\theta \in P_{\mathrm{R}}(X)$, the functions $\hat{u}$ are continuous and separate the points of $P_{\mathrm{R}}(X)$, which is a compact Hausdorff space (437O). By the Stone-Weierstrass theorem (281E), every continuous real-valued function on $P_{\mathrm{R}}(X)$ is uniformly approximated by linear combinations of products of such functions $\hat{u}$, and is therefore $\operatorname{dom}\nu_1$-measurable. It follows at once that all zero sets and all Baire sets are measured by ν_1. **Q**

By 432F, there is a Radon measure $\tilde{\nu}_1$ on $P_{\mathrm{R}}(X)$ agreeing with ν_1 on the Baire sets. In particular, Q^* is $\tilde{\nu}_1$-conegligible. Now

$$\int_{P_{\mathrm{R}}(X)}\int_X u\,d\theta\,\tilde{\nu}_1(d\theta) = \int_{P_{\mathrm{R}}(X)}\hat{u}\,d\nu_1 = \int_{X_0} u\,d\lambda = \int_{X_0} u\,d\tilde{\lambda} = \int_X u\,d\tilde{\lambda}'$$

for every $u \in C(X)$. By 459Fb, $\langle\theta\rangle_{\theta\in P_{\rm R}(X)}$ is a disintegration of $\tilde\lambda'$ over $\tilde\nu_1$.

(e) Because the identity map $\iota : X_0 \to Z$ is continuous, we have a map $\psi : Q^* \to P_{\rm R}(Z)$ defined by saying that $\psi(\theta) = (\theta\restriction\mathcal{P}X_0)\iota^{-1}$ (416Rb, 418I). If $G \subseteq Z$ is open and $\alpha > 0$, then

$$\{\theta : \psi(\theta)(G) > \alpha\} = \{\theta : \theta(G \cap X_0) > \alpha\}$$

is open in $P_{\rm R}(X)$, so ψ is continuous. We therefore have a Radon probability measure $\tilde\nu = (\tilde\nu_1\restriction\mathcal{P}Q^*)\psi^{-1}$ on $P_{\rm R}(Z)$. (Perhaps I should remark here that $P_{\rm R}(Z)$ is a Hausdorff space, by 437Je.)

(f) Suppose that $i_0, \dots, i_r \in I$ are distinct and $G_k \subseteq Z$ is open for each $k \le r$. For each $k \le r$, set $A_k = \{u : u \in C(X),\ 0 \le u \le \chi(X_0 \cap G_k)\}$. For $u \in C(X)$, define $\bar u : Z \to \mathbb{R}$ by setting $\bar u(z) = u(z)$ if $z \in X_0$, 0 if $z \in Z \setminus X_0$. Then $\bar u$ is Borel measurable. Now, writing $\pi_{i_k}(w) = w(i_k)$ for $w \in Z^I$ and $k \le r$,

$$\mu(\textstyle\bigcap_{k\le r}\pi_{i_k}^{-1}[G_k]) = \sup_{u_k\in A_k\forall k\le r}\int(\prod_{k=0}^r \bar u_k\pi_{i_k})d\mu.$$

P Of course

$$\mu(\textstyle\bigcap_{k\le r}\pi_{i_k}^{-1}[G_k]) \ge \sup_{u_k\in A_k\forall k\le r}\int(\prod_{k=0}^r \bar u_k\pi_{i_k})d\mu$$

because $\bar u_k \le \chi G_k$ whenever $u_k \in A_k$. On the other hand, given $\epsilon > 0$, then for each $k \le r$ we have $\tilde\lambda'(G_k \cap X_0) = \lambda G_k$, so there is a $u_k \in A_k$ such that

$$\lambda G_k \le \epsilon + \textstyle\int_X u_k d\tilde\lambda' = \epsilon + \int_{X_0} u_k d\tilde\lambda' = \epsilon + \int_{X_0} u_k d\tilde\lambda = \epsilon + \int_Z \bar u_k d\lambda.$$

Now

$$\textstyle\int \chi G_k\pi_{i_k} - \bar u_k\pi_{i_k} d\mu = \int \chi G_k - \bar u_k d\lambda \le \epsilon$$

for each k, so

$$\begin{aligned}\mu(\bigcap_{k\le r}\pi_{i_k}^{-1}[G_k]) - \int\prod_{k=0}^r \bar u_k\pi_{i_k}d\mu &= \int(\prod_{k=0}^r \chi G_k\pi_{i_k} - \prod_{k=0}^r \bar u_k\pi_{i_k})d\mu\\ &\le \int\sum_{k=0}^r(\chi G_k\pi_{i_k} - \bar u_k\pi_{i_k})d\mu \le (r+1)\epsilon.\end{aligned}$$

Thus

$$\mu(\textstyle\bigcap_{k\le r}\pi_{i_k}^{-1}[G_k]) \le (r+1)\epsilon + \int\prod_{k=0}^r \bar u_k\pi_{i_k}d\mu.$$

As ϵ is arbitrary,

$$\mu(\textstyle\bigcap_{k\le r}\pi_{i_k}^{-1}[G_k]) = \sup_{u_k\in A_k\forall k\le r}\int\prod_{k=0}^r \bar u_k\pi_{i_k}d\mu.$$ **Q**

Next observe that if $u_k \in A_k$ for $k \le r$, then

$$\textstyle\int_{Z^I}\prod_{k=0}^r \bar u_k\pi_{i_k}d\mu = \int_{P_{\rm R}(X)}\big(\prod_{k=0}^r\int u_k d\theta\big)\tilde\nu_1(d\theta).$$

P

$$\int_{Z^I}\prod_{k=0}^r \bar u_k\pi_{i_k}d\mu = \int_Y\int_{Z^I}\prod_{k=0}^r \bar u_k\pi_{i_k}d\mu_y^I\nu(dy)$$

(452F, because $\prod_{k=0}^r \bar u_k\pi_{i_k}$ is $\widehat{\bigotimes}_I\mathcal{B}(Z)$-measurable)

$$\begin{aligned}&= \int_Y(\prod_{k=0}^r\int_Z \bar u_k d\mu_y)\nu(dy) = \int_Y(\prod_{k=0}^r\int_{X_0} \bar u_k d\mu_y)\nu(dy)\\ &= \int_Y(\prod_{k=0}^r\int_{X_0} u_k d\lambda'_y)\nu(dy) = \int_Y(\prod_{k=0}^r\int_X u_k d\lambda'_y)\nu(dy)\\ &= \int_{P_{\rm R}(X)}(\prod_{k=0}^r\int_X u_k d\theta)\nu_1(d\theta)\end{aligned}$$

(235L)

$$= \int_{P_{\rm R}(X)} (\prod_{k=0}^{r} \int_Z u_k d\theta) \tilde{\nu}_1(d\theta)$$

because $\theta \mapsto \prod_{k=0}^r \int_X u_k d\theta$ is continuous, and $\tilde{\nu}_1$ agrees with ν_1 on Baire sets. **Q** Accordingly

$$\tilde{\mu}(\bigcap_{k\le r} \pi_{i_k}^{-1}[G_k]) = \mu(\bigcap_{k\le r} \pi_{i_k}^{-1}[G_k]) = \sup_{u_k \in A_k \forall k \le r} \int_{Z^I} \prod_{k=0}^r \bar{u}_k \pi_{i_k} d\mu$$

$$= \sup_{u_k \in A_k \forall k \le r} \int_{P_{\rm R}(X)} (\prod_{k=0}^r \int_X u_k d\theta) \tilde{\nu}_1(d\theta)$$

$$= \int_{P_{\rm R}(X)} \sup_{u_k \in A_k \forall k \le r} (\prod_{k=0}^r \int_X u_k d\theta) \tilde{\nu}_1(d\theta)$$

(because $\tilde{\nu}_1$ is τ-additive and the functions $\theta \mapsto \prod_{k=0}^r \int_X u_k d\theta$ are continuous and the sets A_k are upwards-directed)

$$= \int_{P_{\rm R}(X)} (\prod_{k=0}^r \sup_{u_k \in A_k} \int_X u_k d\theta) \tilde{\nu}_1(d\theta)$$

$$= \int_{P_{\rm R}(X)} \prod_{k=0}^r \theta(G_k \cap X_0) \tilde{\nu}_1(d\theta)$$

(because every θ is τ-additive, and $G_k \cap X_0$ is an open set in the completely regular space X)

$$= \int_{Q^*} \prod_{k=0}^r \theta(G_k \cap X_0) \tilde{\nu}_1(d\theta)$$

$$= \int_{Q^*} \prod_{k=0}^r \psi(\theta)(G_k) \tilde{\nu}_1(d\theta) = \int_{P_{\rm R}(Z)} \prod_{k=0}^r \theta(G_k) \tilde{\nu}(d\theta)$$

(235L again)

$$= \int_{P_{\rm R}(Z)} \tilde{\theta}^I (\bigcap_{k\le r} \pi_{i_k}^{-1}[G_k]) \tilde{\nu}(d\theta),$$

where I write $\tilde{\theta}^I$ to indicate that I intend to use the Radon product measure, even though in this formula it makes no difference which product measure is employed.

(g) What this means is that $\tilde{\mu}W = \int \tilde{\theta}^I W \, \tilde{\nu}(d\theta)$ for every open measurable cylinder W. Since the map $\theta \mapsto \tilde{\theta}^I : P_{\rm R}(Z) \to P_{\rm R}(Z^I)$ is continuous (437Mb), 459Fa tells us that $\langle \tilde{\theta}^I \rangle_{\theta \in P_{\rm R}(Z)}$ is a disintegration of $\tilde{\mu}$ over $\tilde{\nu}$, as required.

459H Following the results of §452 (especially 452Ye), we do not generally expect to find disintegrations of measures which are not countably compact. It may however illuminate the constructions here if I give a specific example related to the contexts of 459E and 459G.

Example (Dubins & Freedman 79) There are a separable metrizable space Z and a quasi-Radon measure on $Z^{\mathbb{N}}$, invariant under permutations of coordinates, which cannot be disintegrated into powers of measures on Z.

proof (a) Let λ be Lebesgue measure on $[0,1]$. $Q = [0,1] \times [0,1]^{\mathbb{N}}$, with its usual topology, is a compact metrizable space, so has just $\mathfrak{c}$ Borel sets (4A3F). Let $\langle W_\xi \rangle_{\xi < \mathfrak{c}}$ enumerate the Borel subsets of Q with non-zero measure for the product measure $\lambda \times \lambda^{\mathbb{N}}$. (Remember that $\lambda \times \lambda^{\mathbb{N}}$ is a Radon measure, by 416U.) For each ξ, we have $0 < (\lambda \times \lambda^{\mathbb{N}})(W_\xi) = \int \lambda^{\mathbb{N}}(W_\xi[\{t\}]) \lambda(dt)$, so $A_\xi = \{t : W_\xi[\{t\}] \neq \emptyset\}$ has cardinal $\mathfrak{c}$ (419Ia); we can therefore choose $\langle t_\xi \rangle_{\xi < \mathfrak{c}}$ in $[0,1]$ such that $t_\xi \in A_\xi \setminus \{t_\eta : \eta < \xi\}$ for every $\xi < \mathfrak{c}$. Now choose $t_{\xi n}$, for $\xi < \mathfrak{c}$ and $n \in \mathbb{N}$, such that $(t_\xi, \langle t_{\xi n} \rangle_{n \in \mathbb{N}}) \in W_\xi$. Set $Z = \{(t_\xi, t_{\xi n}) : \xi < \mathfrak{c}, n \in \mathbb{N}\} \subseteq [0,1]^2$.

(b) Set $X = ([0,1]^2)^{\mathbb{N}}$ and define $\phi : Q \to X$ by setting $\phi(t, \langle t_n\rangle_{n\in\mathbb{N}}) = \langle (t, t_n)\rangle_{n\in\mathbb{N}}$ for t, $t_n \in [0,1]$. Then ϕ is a homeomorphism between Q and $\phi[Q]$, so there is a unique Radon measure $\mu^\#$ on X such that ϕ is inverse-measure-preserving for $\lambda \times \lambda^{\mathbb{N}}$ and $\mu^\#$. Now $\mu^\#$ is invariant under permutations of coordinates, because if $\rho : \mathbb{N} \to \mathbb{N}$ is a permutation and $\hat\rho(x) = x\rho$ for $x \in X$, then $\hat\rho\phi = \phi\bar\rho$, where $\bar\rho(t, \langle t_n\rangle_{n\in\mathbb{N}}) = (t, \langle t_{\rho(n)}\rangle_{n\in\mathbb{N}})$; and as $\bar\rho : Q \to Q$ is inverse-measure-preserving, so is $\hat\rho : X \to X$.

Also $Z^{\mathbb{N}}$ has full outer measure for $\mu^\#$. **P** If $\mu^\# W > 0$, then $(\lambda \times \lambda^{\mathbb{N}})\phi^{-1}[W] > 0$, so there is some $\xi < \mathfrak{c}$ such that $W_\xi \subseteq \phi^{-1}[W]$. Now $\langle (t_\xi, t_{\xi n})\rangle_{n\in\mathbb{N}} \in Z^{\mathbb{N}} \cap W$. **Q** Accordingly the subspace measure $\tilde\mu$ on Z is a probability measure. Because $\mu^\#$ is invariant under permutations of coordinates, so is $\tilde\mu$; because $\mu^\#$ is a Radon measure, $\tilde\mu$ is a quasi-Radon measure (416Ra).

(c) **?** Suppose, if possible, that there are a probability space (Y, T, ν) and a family $\langle \mu_y\rangle_{y\in Y}$ of probability measures on Z such that $\tilde\mu E = \int \mu_y^{\mathbb{N}} E\, \nu(dy)$ for every Borel set $E \subseteq Z^{\mathbb{N}}$. (The argument to follow will not depend on which product measure is used in forming the $\mu_y^{\mathbb{N}}$.) Looking at sets of the form $(Z \cap H) \times Z \times Z \times \dots$, where $H \subseteq [0,1]^2$ is a Borel set, we see that $\mu_y(Z \cap H)$ must be defined for almost every y; as Z is second-countable, μ_y must be a topological measure for almost every y. Looking at sets of the form $(Z \cap (G_0 \times [0,1])) \times (Z \cap (G_1 \times [0,1])) \times Z \times \dots$, where G_0 and G_1 are disjoint Borel subsets of $[0,1]$, we see that $\mu_y(Z \cap (G_0 \times [0,1])) \cdot \mu_y(Z \cap (G_1 \times [0,1])) = 0$ for almost every y; as $[0,1]$ is second-countable and Hausdorff, there must be, for almost every $y \in Y$, an $s_y \in [0,1]$ such that $\mu_y(Z \cap (\{s_y\} \times [0,1])) = 1$.

Next, if $G \subseteq [0,1]$ is a Borel set, then $\mu_y(Z \cap ([0,1] \times G)) = \lambda G$ for almost every y. **P**

$$h(y) = \mu_y^{\mathbb{N}}((Z \cap ([0,1] \times G)) \times Z \times \dots) = \mu_y(Z \cap ([0,1] \times G))$$

is defined for almost every y, and h is ν-integrable, with

$$\int h\, d\nu = \tilde\mu((Z \cap ([0,1] \times G)) \times Z \times \dots) = \mu^\#(([0,1] \times G) \times [0,1]^2 \times \dots) = \lambda G.$$

At the same time,

$$\begin{aligned}\int h(y)(1-h(y))\nu(dy) &= \tilde\mu((Z \cap ([0,1] \times G)) \times (Z \cap ([0,1] \times ([0,1] \setminus G))) \times Z \times \dots)\\ &= \mu^\#(([0,1] \times G) \times ([0,1] \times ([0,1] \setminus G)) \times [0,1]^2 \times \dots)\\ &= \lambda G(1 - \lambda G).\end{aligned}$$

Rearranging, we see that $\int h^2 d\nu = (\int h)^2$. But this means that $\int (h(y) - \int h)^2 \nu(dy) = 0$ and $h(y) = \lambda G$ for almost every y. **Q**

It follows that, for at least some y, $\mu_y(Z \cap (\{s_y\} \times G)) = \lambda G$ for every interval $G \subseteq [0,1]$ with rational endpoints. But this is impossible, because all the vertical sections of Z are countable. **X**

Thus there is no such disintegration, as claimed.

459X Basic exercises (a) Let (X, Σ, μ) be a probability space and $\langle f_n\rangle_{n\in\mathbb{N}}$ an exchangeable sequence of real-valued random variables on X all with finite expectation. Use 459C and 273I to show that $\langle \frac{1}{n+1}\sum_{i=0}^n f_i\rangle_{n\in\mathbb{N}}$ converges a.e. (Compare 276Xe.)

(b) Let (X, Σ, μ) be a probability space and $\langle f_n\rangle_{n\in\mathbb{N}}$ an exchangeable sequence of real-valued random variables on X all with finite variance, such that $\lim_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^n f_i = 0$ a.e. Show that $\langle \Pr(\sum_{i=0}^n f_i \geq \alpha\sqrt{n+1})\rangle_{n\in\mathbb{N}}$ is convergent for every $\alpha \in \mathbb{R}$. (*Hint*: 274I.)

>(c) (Diaconis & Freedman 80) Let X be a non-empty compact Hausdorff space and I an infinite set including $\mathbb{N}$. Let $\tilde\lambda$ be a Radon probability measure on X^I invariant under permutations of I. For $k \leq n$ let $D_{nk} \subseteq n^k$ be the set of injective functions from k to n and Ω_{nk} the set $X^I \times n^k \times D_{nk}$, endowed with the product ν_{nk} of $\tilde\lambda$ and the uniform probability measures on the finite sets n^k and D_{nk}. Define $f_{nk} : \Omega_{nk} \to X^k$ and $g_{nk} : \Omega_{nk} \to X^k$ by setting

$$\begin{aligned}f_{nk}(w,p,q) &= wp,\\ g_{nk}(w,p,q) &= wp \text{ if } p \in D_{nk}\\ &= wq \text{ otherwise.}\end{aligned}$$

(i) Show that there is a disintegration $\langle \mu^k_{nw} \rangle_{w \in X^I}$ of the image measure $\nu_{nk} f_{nk}^{-1}$ over $\tilde{\lambda}$ where each μ_{nw} is a suitable point-supported measure. (ii) Show that the image measure $\nu_{nk} g_{nk}^{-1}$ is the image measure $\tilde{\lambda}_k = \tilde{\lambda}\tilde{\pi}_k^{-1}$, where $\tilde{\pi}_k(w) = w \restriction k$ for $w \in X^I$. (iii) Show that $|\tilde{\lambda}_k W - \int \mu^k_{nw} W \, \tilde{\lambda}(dw)| \leq \frac{k(k-1)}{2n}$ for every Baire set $W \subseteq X^k$. (iv) Show that there is a Radon probability measure θ_n on $P_{\mathrm{R}}(X)$ for which $w \mapsto \mu_{nw}$ is inverse-measure-preserving. (v) Show that if θ is any cluster point of $\langle \theta_n \rangle_{n \in \mathbb{N}}$ in $P_{\mathrm{R}}(X)$ then $\langle \tilde{\mu}^I \rangle_{\mu \in P_{\mathrm{R}}(X)}$ is a disintegration of $\tilde{\lambda}$ over θ, writing $\tilde{\mu}^I$ for the Radon product of copies of any $\mu \in P_{\mathrm{R}}(X)$.

>(d) (Hewitt & Savage 55) Let X be a non-empty compact Hausdorff space and I an infinite set. Let Q be the set of Radon probability measures on X^I which are invariant under permutations of I. Show that (i) Q is a closed convex subset of the set $P_{\mathrm{R}}(X^I)$ of all Radon probability measures on X^I with its narrow topology; (ii) Q is isomorphic, as topological convex structure, to $P_{\mathrm{R}}(P_{\mathrm{R}}(X))$; (iii) the extreme points of Q are just the powers of Radon probability measures on X.

(e) Let X be a non-empty Hausdorff space. Let Q be the set of Radon probability measures on $X^{\mathbb{N}}$ which are invariant under permutations of $\mathbb{N}$. Show that (i) Q is a closed convex subset of the set $P_{\mathrm{R}}(X^{\mathbb{N}})$ of all Radon probability measures on $X^{\mathbb{N}}$ with its narrow topology; (ii) Q is isomorphic, as topological convex structure, to $P_{\mathrm{R}}(P_{\mathrm{R}}(X))$; (iii) the extreme points of Q are just the powers of Radon probability measures on X.

459Y Further exercises (a) Discuss the problems which arise in 459B, 459C, 459E and 459G if the index set I is finite.

459 Notes and comments As I have presented this material, the centre of the argument is the martingales in part (b) of the proof of 459B. We are trying to resolve the functions f_i into 'common' and 'independent' parts. The 'common' part is given by the conditional expectations of the f_i over an appropriate σ-algebra T, and we approach these by looking at the conditional expectations of each f_i on σ-algebras T_n generated by 'distant' f_j. All the most important ideas are already exhibited when the index set I is equal to $\mathbb{N}$. Note in particular that in the basic hypothesis that all finite strings $(f_{i_0}, \ldots, f_{i_r})$ have the same joint distribution, it is enough to look at increasing strings. But there is a striking phenomenon which appears in sharper relief with uncountable sets I: any sequence $\langle j_k \rangle_{k \in \mathbb{N}}$ of distinct elements of I can be used to generate an adequate σ-algebra, because while the tail σ-algebra of sets depends on the choice of the j_k, they all lead to the same closed subalgebra of the measure algebra (459D).

Perhaps I should emphasize at this point that I really does have to be infinite, though for large finite I there are approximations to the results here.

The proof of 459B is one of the standard proofs of de Finetti's theorem, with trifling modifications. In the case of real-valued random variables we have a notion of relative distribution (458C) which gives a quick way of saying that all the f_i have the same conditional expectations over T, as in 459C(ii). For variables taking values in other spaces the situation may be different (459H), unless (as in §452) we have a countably compact measure (459E).

Specializing to the case $X = Z^I$ in 459B, we find ourselves examining symmetric measures on infinite product spaces, which are of great interest in themselves. Note that while in the hypothesis of 459E I have asked for the measure μ on the product space Z^I to be countably compact, what is actually necessary is that the marginal measure on Z should be countably compact. By 454A, this comes to the same thing.

As in 452O, we can look for a disintegration consisting of Radon measures, provided of course that the marginal measure is a Radon measure. What we have to work harder for is a direct expression in terms of an integral $\int \tilde{\theta}^I \tilde{\nu}(d\theta)$ where $\tilde{\nu}$ is itself a Radon probability measure on the space of Radon probability measures θ (459G). But most of the extra work consists of finding the correct reduction to the case of compact spaces. For compact spaces we can approach by a completely different route (459Xc). I will not go farther with this idea here, but I note that the method can be used in a wide variety of problems involving symmetric structures.

Chapter 46

Pointwise compact sets of measurable functions

This chapter collects results inspired by problems in functional analysis. §§461 and 466 look directly at measures on linear topological spaces. The primary applications are of course to Banach spaces, but as usual we quickly find ourselves considering weak topologies. In §461 I look at 'barycenters', or centres of mass, of probability measures, with the basic theorems on existence and location of barycenters of given measures and the construction of measures with given barycenters. In §466 I examine topological measures on linear spaces in terms of the classification developed in Chapter 41. A special class of normed spaces, those with 'Kadec norms', is particularly important, and in §467 I sketch the theory of the most interesting Kadec norms, the 'locally uniformly rotund' norms.

In the middle sections of the chapter, I give an account of the theory of pointwise compact sets of measurable functions, as developed by A.Bellow, M.Talagrand and myself. The first step is to examine pointwise compact sets of continuous functions (§462); these have been extensively studied because they represent an effective tool for investigating weakly compact sets in Banach spaces, but here I give only results which are important in measure theory, with a little background material. In §463 I present results on the relationship between the two most important topologies on spaces of measurable functions, *not* identifying functions which are equal almost everywhere: the pointwise topology and the topology of convergence in measure. These topologies have very different natures but nevertheless interact in striking ways. In particular, we have important theorems giving conditions under which a pointwise compact set of measurable functions will be compact for the topology of convergence in measure (463F, 463K).

The remaining two sections are devoted to some remarkable ideas due to Talagrand. The first, 'Talagrand's measure' (§464), is a special measure on $\mathcal{P}I$ (or $\ell^\infty(I)$), extending the usual measure of $\mathcal{P}I$ in a canonical way. In §465 I turn to the theory of 'stable' sets of measurable functions, showing how a concept arising naturally in the theory of pointwise compact sets led to a characterization of Glivenko-Cantelli classes in the theory of empirical measures.

461 Barycenters and Choquet's theorem

One of the themes of this chapter will be the theory of measures on linear spaces, and the first fundamental concept is that of 'barycenter' of a measure, its centre of mass (461Aa). The elementary theory (461B-461D) uses non-trivial results from the theory of locally convex spaces (§4A4), but is otherwise natural and straightforward. It is not always easy to be sure whether a measure has a barycenter in a given space, and I give a representative pair of results in this direction (461E, 461G). Deeper questions concern the existence and nature of measures on a given compact set with a given barycenter. The Riesz representation theorem is enough to tell us just which points can be barycenters of measures on compact sets (461H). A new idea (461J) shows that the measures can be moved out towards the boundary of the compact set. We need a precise definition of 'boundary'; the set of extreme points seems to be the appropriate concept (461N).

461A Definitions (a) Let X be a Hausdorff locally convex linear topological space, and μ a probability measure on a subset A of X. Then $x^* \in X$ is the **barycenter** or **resultant** of μ if $\int_A f d\mu$ is defined and equal to $f(x^*)$ for every $f \in X^*$. Because X^* separates the points of X (4A4Ec), μ can have at most one barycenter.

(b) Let X be any real linear space, and $C \subseteq X$ a convex set (definition: 2A5E). Then a function $g : C \to \mathbb{R}$ is **convex** if $g(tx + (1-t)y) \leq tg(x) + (1-t)g(y)$ for all x, $y \in C$ and $t \in [0,1]$. (Compare 233G, 233Xd.)

(c) The following elementary remark is useful. Let X be a linear space over $\mathbb{R}$, $C \subseteq X$ a convex set, and $g : C \to \mathbb{R}$ a function. Then g is convex iff the set $\{(x,\alpha) : x \in C, \alpha \geq g(x)\}$ is convex in $X \times \mathbb{R}$ (cf. 233Xd).

461B Proposition Let X and Y be Hausdorff locally convex linear topological spaces, and $T : X \to Y$ a continuous linear operator. Suppose that $A \subseteq X$, $B \subseteq Y$ are such that $T[A] \subseteq B$, and let μ be a probability measure on A which has a barycenter x^* in X. Then Tx^* is the barycenter of the image measure μT^{-1} on B.

proof All we have to observe is that if $g \in Y^*$ then $gT \in X^*$ (4A4Bd), so that

$$g(Tx^*) = \int_A g(Tx)\mu(dx) = \int_B g(y)\nu(dy)$$

by 235I.

461C Theorem Let X be a Hausdorff locally convex linear topological space, $C \subseteq X$ a convex set and μ a topological probability measure on a subset A of C. Suppose that μ has a barycenter x^* in X which belongs to C. Then $g(x^*) \leq \int_A g\,d\mu$ for every lower semi-continuous convex function $g : C \to \mathbb{R}$.

proof Take any $\gamma < g(x^*)$. Let D be the convex set $\{(x,\alpha) : x \in C,\ \alpha \geq g(x)\}$ in $X \times \mathbb{R}$ (461Ac). Then the closure $\overline{D}$ of D is also convex (2A5Eb). Now $(x^*,\gamma) \notin \overline{D}$. **P** Set $\delta = \frac{1}{2}(g(x^*) - \gamma) > 0$. As g is lower semi-continuous, there is an open neighbourhood G of x^* such that $g(x) \geq g(x^*) - \delta$ for every $x \in C \cap G$, so that $G \times]-\infty, \gamma + \delta[$ is an open set containing (x^*,γ) and disjoint from D. **Q**

Consequently there is a continuous linear functional $h : X \times \mathbb{R} \to \mathbb{R}$ such that $h(x^*,\gamma) < \inf_{w \in \overline{D}} h(w)$ (4A4Eb). Now there are $f \in X^*$, $\beta \in \mathbb{R}$ such that $h(x,\alpha) = f(x) + \alpha\beta$ for every $x \in X$, $\alpha \in \mathbb{R}$ (4A4Be). So we have

$$f(x^*) + \beta\gamma = h(x^*,\gamma) < h(x, g(x)) = f(x) + \beta g(x)$$

for every $x \in C$. In particular, $f(x^*) + \beta\gamma < f(x^*) + \beta g(x^*)$, so $\beta > 0$. Integrating with respect to μ, we have

$$f(x^*) + \beta\gamma < \int_A f\,d\mu + \beta \int_A g\,d\mu = f(x^*) + \beta \int_A g\,d\mu,$$

and $\gamma < \int_A g\,d\mu$. As γ is arbitrary, $g(x^*) \leq \int_A g\,d\mu$.

Remark Of course $\int_A g\,d\mu$ might be infinite.

461D Theorem Let X be a Hausdorff locally convex linear topological space, and μ a probability measure on X such that (i) the domain of μ includes the cylindrical σ-algebra of X (ii) there is a compact convex set $K \subseteq X$ such that $\mu^* K = 1$. Then μ has a barycenter in X, which belongs to K.

proof If $f \in X^*$, then $\gamma_f = \sup_{x \in K} |f(x)|$ is finite, and $\{x : |f(x)| \leq \gamma_f\}$ is a measurable set including K, so must be conegligible, and $\phi(f) = \int f d\mu$ is defined and finite. Now $\phi : X^* \to \mathbb{R}$ is a linear functional and $\phi(f) \leq \sup_{x \in K} f(x)$ for every $f \in X^*$; because K is compact and convex, there is an $x_0 \in K$ such that $\phi(f) = f(x_0)$ for every $f \in X^*$ (4A4Ef), so that x_0 is a barycenter of μ in X.

461E Theorem Let X be a complete locally convex linear topological space, and $A \subseteq X$ a bounded set. Let μ be a τ-additive topological probability measure on A. Then μ has a barycenter in X.

proof (a) If $f \in X^*$, then $f \restriction A$ is continuous and bounded (4A4Bg), therefore μ-integrable. For each open neighbourhood G of 0 in X, set

$$F_G = \{y : y \in X,\ |f(y) - \int_A f d\mu| \leq 2\tau_G(f) \text{ for every } f \in X^*\}$$

where $\tau_G(f) = \sup_{x \in G} f(x)$ for $f \in X^*$. Then F_G is non-empty. **P** Set $H = \operatorname{int}(G \cap (-G))$, so that H is an open neighbourhood of 0. Because $\overline{A}$ is bounded, there is an $m \geq 1$ such that $A \subseteq mH$. The set $\{x + H : x \in A\}$ is an open cover of A, and μ is a τ-additive topological measure, so there are $x_0, \ldots, x_n \in A$ such that $\mu(A \setminus \bigcup_{i \leq n}(x_i + H)) \leq \frac{1}{m}$. Set

$$E_i = A \cap (x_i + H) \setminus \bigcup_{j<i}(x_j + H)$$

for $i \leq n$, and $y = \sum_{i=0}^n (\mu E_i) x_i$; set $E = A \setminus \bigcup_{i \leq n}(x_i + H)$. Then, for any $f \in X^*$,

$$|f(y) - \int_A f d\mu| \leq \sum_{i=0}^{n} |\mu E_i f(x_i) - \int_{E_i} f d\mu| + \int_E |f| d\mu$$
$$\leq \sum_{i=0}^{n} \int_{E_i} |f(x) - f(x_i)| \mu(dx) + m\tau_G(f)\mu E$$
(because $E \subseteq mH$, so $f(x) \leq m\tau_G(f)$ and $f(-x) \leq m\tau_G(f)$ for every $x \in E$)
$$\leq \sum_{i=0}^{n} \tau_G(f)\mu E_i + m\tau_G(f)\mu E$$
(because if $i \leq n$ and $x \in E_i$, then $x - x_i$ and $x_i - x$ belong to G, so $|f(x) - f(x_i)| = |f(x - x_i)| \leq \tau_G(f)$)
$$\leq 2\tau_G(f).$$

As f is arbitrary, $y \in F_G$ and $F_G \neq \emptyset$. **Q**

(c) Since $F_{G \cap H} \subseteq F_G \cap F_H$ for all neighbourhoods G and H of 0, $\{F_G : G \text{ is a neighbourhood of } 0\}$ is a filter base and generates a filter $\mathcal{F}$ on X. Now $\mathcal{F}$ is Cauchy. **P** If G is any neighbourhood of 0, let $G_1 \subseteq G$ be a closed convex neighbourhood of 0, and set $H = \frac{1}{4}G_1$. **?** If $y, y' \in F_H$ and $y - y' \notin G$, then there is an $f \in X^*$ such that $f(y - y') > \tau_{G_1}(f)$ (4A4Eb). But now

$$\tau_H(f) = \frac{1}{4}\tau_{G_1}(f) < \frac{1}{4}(|f(y) - \textstyle\int_A f d\mu| + |f(y') - \int_A f d\mu|) \leq \frac{1}{4}(2\tau_H(f) + 2\tau_H(f)).$$ **X**

This means that $F_H - F_H \subseteq G$; as G is arbitrary, $\mathcal{F}$ is Cauchy. **Q**

(d) Because X is complete, $\mathcal{F}$ has a limit x^* say. Take any $f \in X^*$. **?** If $f(x^*) \neq \int_A f d\mu$, set $G = \{x : |f(x)| \leq \frac{1}{3}|f(x^*) - \int_A f d\mu|\}$. Then G is a neighbourhood of 0 in X, and

$$|f(x^*) - \int_A f d\mu| = \lim_{x \to \mathcal{F}} |f(x) - \int_A f d\mu| \leq \sup_{x \in F_G} |f(x) - \int_A f d\mu|$$
$$\leq 2\tau_G(f) \leq \frac{2}{3}|f(x^*) - \int_A f d\mu|.$$ **X**

So $f(x^*) = \int_A f d\mu$; as f is arbitrary, x^* is a barycenter of μ.

461F Lemma Let X be a normed space, and μ a probability measure on X such that every member of the dual X^* of X is integrable. Then $f \mapsto \int f d\mu : X^* \to \mathbb{R}$ is a bounded linear functional on X^*.

proof Replacing μ by its completion if necessary, we may suppose that μ is complete, so that every member of X^* is Σ-measurable, where Σ is the domain of μ. (The point is that μ and its completion give rise to the same integrals, by 212Fb.) For each $n \in \mathbb{N}$ let E_n be a measurable envelope of $B_n = \{x : \|x\| \leq n\}$; replacing E_n by $\bigcap_{i \geq n} E_i$ if necessary, we may suppose that $\langle E_n \rangle_{n \in \mathbb{N}}$ is non-decreasing. If $n \in \mathbb{N}$, $f \in X^*$ then $\{x : x \in E_n, |f(x)| > n\|f\|\}$ is a measurable subset of E_n disjoint from B_n, so must be negligible, and $|\int_{E_n} f| \leq n\|f\|$. We therefore have an element ϕ_n of X^{**} defined by setting $\phi_n(f) = \int_{E_n} f$ for every $f \in X^*$. But also $\phi(f) = \lim_{n \to \infty} \phi_n(f)$ for every f, because $\langle E_n \rangle_{n \in \mathbb{N}}$ is a non-decreasing sequence of measurable sets with union X. By the Uniform Boundedness Theorem (3A5Ha), $\{\phi_n : n \in \mathbb{N}\}$ is bounded in X^{**}, and $\phi \in X^{**}$, with $\|\phi\| \leq \sup_{n \in \mathbb{N}} \|\phi_n\|$.

461G Proposition Let X be a reflexive Banach space, and μ a probability measure on X such that every member of X^* is μ-integrable. Then μ has a barycenter in X.

proof By 461F, $f \mapsto \int f$ is a bounded linear functional on X^*; but this means that it is represented by a member of X, which is a barycenter of μ.

461H Theorem Let X be a Hausdorff locally convex linear topological space, and $K \subseteq X$ a compact set. Then the closed convex hull of K in X is just the set of barycenters of Radon probability measures on K.

proof (a) If μ is a Radon probability measure on K with barycenter x^*, then

$$f(x^*) = \int_K f(x)\mu(dx) \leq \sup_{x\in K} f(x) \leq \sup_{x\in\overline{\Gamma(K)}} f(x);$$

because $\overline{\Gamma(K)}$ is closed and convex, it must contain x^* (4A4Eb).

(b) Now suppose that $x^* \in \overline{\Gamma(K)}$. Let $W \subseteq C(X)$ be the set of functionals of the form $f + \alpha\chi X$, where $f \in X^*$ and $\alpha \in \mathbb{R}$. Set $U = \{f\restriction K : f \in W\}$, so that U is a linear subspace of $C(K)$ containing χK.

If f_1, $f_2 \in W$ and $f_1\restriction K = f_2\restriction K$, then $\{x : f_1(x) = f_2(x)\}$ is a closed convex set including K, so contains x^*, and $f_1(x^*) = f_2(x^*)$; accordingly we have a functional $\phi : U \to \mathbb{R}$ defined by setting $\phi(f\restriction K) = f(x^*)$ for every $f \in W$. Of course ϕ is linear; moreover, $\phi(g) \leq \sup_{x\in K} g(x)$ for every $g \in U$, by 4A4Eb. Applying this to $\pm g$, we see that $|\phi(g)| \leq \|g\|_\infty$ for every $g \in U$. We therefore have an extension of ϕ to a continuous linear functional ψ on $C(K)$ such that $\|\psi\| \leq 1$, by the Hahn-Banach theorem (3A5Ab). Now

$$\psi(\chi K) = \phi(\chi K) = \chi X(x^*) = 1;$$

so if $0 \leq h \leq \chi K$ then

$$|1 - \psi(h)| = |\psi(\chi K - h)| \leq \|\chi K - h\|_\infty \leq 1,$$

and $\psi(h) \geq 0$. It follows that $\psi(h) \geq 0$ for every $h \in C(K)^+$. But this means that there is a Radon probability measure μ on K such that $\psi(h) = \int h\,d\mu$ for every $h \in C(K)$ (436J/436K). As $\mu K = \psi(\chi K) = 1$, μ is a probability measure; and for any $f \in X^*$

$$\int_K f d\mu = \psi(f\restriction K) = \phi(f\restriction K) = f(x^*),$$

so x^* is the barycenter of μ, as required.

461I Corollary: Kreĭn's theorem Let X be a complete Hausdorff locally convex linear topological space, and $K \subseteq X$ a weakly compact set. Then the closed convex hull $\overline{\Gamma(K)}$ of K is weakly compact.

proof Give K the weak topology induced by $\mathfrak{T}_s(X, X^*)$. Let P be the set of Radon probability measures on K (or, if you prefer, the set of tight Borel probability measures) with the narrow topology, so that P is compact (437O). By 461E, every $\mu \in P$ has a barycenter $b(\mu)$ in K. If $f \in X^*$, $f(b(\mu)) = \int_K f d\mu$, while $f\restriction K$ is continuous; so $b : P \to X$ is continuous for the vague topology on P and the weak topology on X. Accordingly $b[P]$ is weakly compact. But $b[P]$ is the weakly closed convex hull of K, by 461H applied to the weak topology on X. By 4A4Ed, $\Gamma(K)$ has the same closure for the original topology of X as it has for the weak topology, and $\overline{\Gamma(K)} = b[P]$ is weakly compact.

461J Lemma Let X be a Hausdorff locally convex linear topological space, and K a compact convex subset of X. Then for any $x^* \in K$ there is a Radon probability measure μ on K such that x^* is the barycenter of μ and $\mu\{\frac{1}{2}(x + y) : x \in M_1, y \in M_2\} = 0$ for all disjoint closed convex subsets M_1, M_2 of K.

proof (a) Let $P \subseteq C(K)^*$ be the set of linear functionals ϕ such that (i) $\phi(g) \geq 0$ for every non-negative $g \in C(K)$ (ii) $\phi(\chi K) = 1$ (iii) $\phi(f\restriction K) = f(x^*)$ for every $f \in X^*$. Then P is a weak*-closed subset of the unit ball of $C(K)^*$, so is compact for the weak* topology on $C(K)^*$ (3A5F). In the proof of 461H we found a Radon probability measure on K with barycenter x^* precisely by finding a member of P, so P is not empty.

(b) For ϕ, $\psi \in P$, say that $\phi \preccurlyeq \psi$ if $\phi(g) \leq \psi(g)$ for every convex continuous function $g : K \to \mathbb{R}$. Then $\preccurlyeq$ is reflexive and transitive, and $R_\phi = \{\psi : \psi \in P, \phi \preccurlyeq \psi\}$ is closed for every $\phi \in P$. Let $Q \subseteq P$ be a maximal set such that $\{R_\phi : \phi \in Q\}$ has the finite intersection property; then $\bigcap_{\phi\in Q} R_\phi$ is not empty; fix $\tilde{\phi}$ in the intersection. Of course $\tilde{\phi} \in P$ (because Q is not empty). Note that if $\psi \in P$ and $\tilde{\phi} \preccurlyeq \psi$, then $\{R_\phi : \phi \in Q \cup \{\psi\}\}$ has non-empty intersection, so that $\psi \in Q$ and $\psi \preccurlyeq \tilde{\phi}$.

Let $\tilde{\mu}$ be the Radon probability measure on K corresponding to $\tilde{\phi}$, so that x^* is the barycenter of $\tilde{\mu}$.

(c) Now take disjoint closed convex sets M_1, $M_2 \subseteq K$, and set $M = \{\frac{1}{2}(x + y) : x \in M_1, y \in M_2\}$.

? Suppose, if possible, that $\tilde{\mu}M > 0$. Set $q(x, y) = \frac{1}{2}(x+y)$ for $x \in M_1$, $y \in M_2$, so that $q : M_1 \times M_2 \to M$ is continuous. Let $\tilde{\mu}_M$ be the subspace measure on M induced by $\tilde{\mu}$, so that $\tilde{\mu}_M$ is a Radon measure on M (416Rb). Let λ be a Radon measure on $M_1 \times M_2$ such that $\tilde{\mu}_M = \lambda q^{-1}$ (418L), and define $\psi : C(K) \to \mathbb{R}$ by writing

$$\psi(g) = \int_{K\setminus M} g\,d\tilde\mu + \int_{M_1\times M_2} \tfrac12(g(x)+g(y))\lambda(d(x,y)).$$

Then ψ is linear, $\psi(g) \geq 0$ whenever $g \in C(K)^+$, and

$$\psi(\chi K) = \tilde\mu(K\setminus M) + \lambda(M_1\times M_2) = \tilde\mu(K\setminus M) + \tilde\mu_M(M) = 1.$$

If $g : K \to \mathbb{R}$ is continuous and convex, then

$$\begin{aligned}
\psi(g) &= \int_{K\setminus M} g\,d\tilde\mu + \int_{M_1\times M_2} \tfrac12(g(x)+g(y))\lambda(d(x,y)) \\
&\geq \int_{K\setminus M} g\,d\tilde\mu + \int_{M_1\times M_2} g(\tfrac12(x+y))\lambda(d(x,y)) \\
&= \int_{K\setminus M} g\,d\tilde\mu + \int_{M_1\times M_2} gq\,d\lambda \\
&= \int_{K\setminus M} g\,d\tilde\mu + \int_M g\,d\tilde\mu_M \\
&\text{(235I)} \\
&= \int_K g\times\chi(K\setminus M)d\tilde\mu + \int_K g\times\chi M\,d\tilde\mu \\
&\text{(131Fa)} \\
&= \int_K g\,d\tilde\mu = \tilde\phi(g).
\end{aligned}$$

Applying this to $\pm f\restriction K$, we see that $\psi(f\restriction K) = \tilde\phi(f\restriction K) = f(x^*)$ for every $f \in X^*$, so that $\psi \in P$. Also $\tilde\phi \preccurlyeq \psi$, so (as remarked in (b)) $\psi \preccurlyeq \tilde\phi$.

Because M_1 and M_2 are disjoint non-empty compact convex sets in the Hausdorff locally convex space X, there are an $f \in X^*$ and an $\alpha \in \mathbb{R}$ such that $f(x) < \alpha < f(y)$ whenever $x \in M_1$, $y \in M_2$ (4A4Ee). Set $g(x) = |f(x) - \alpha|$ for $x \in K$; then g is a continuous convex function. If $x \in M_1$ and $y \in M_2$, then

$$\begin{aligned}
g(\tfrac12(x+y)) &= |f(\tfrac12(x+y)) - \alpha| = \tfrac12|(f(x)-\alpha) + (f(y)-\alpha)| \\
&< \tfrac12(|f(x)-\alpha| + |f(y)-\alpha|) = \tfrac12(g(x)+g(y)).
\end{aligned}$$

Looking at the formulae above for $\psi(g)$, we see that we have

$$\begin{aligned}
\psi(g) &= \int_{K\setminus M} g\,d\tilde\mu + \int_{M_1\times M_2} \tfrac12(g(x)+g(y))\lambda(d(x,y)) \\
&> \int_{K\setminus M} g\,d\tilde\mu + \int_{M_1\times M_2} g(\tfrac12(x+y))\lambda(d(x,y)) = \tilde\phi(g)
\end{aligned}$$

(because $\lambda(M_1\times M_2) = \tilde\mu M > 0$). But this means that $\psi \not\preccurlyeq \tilde\phi$, which is impossible. **X**

Thus $\tilde\mu M = 0$. As M_1 and M_2 are arbitrary, $\tilde\mu$ has the properties required.

461K Choquet's theorem Let X be a Hausdorff locally convex linear topological space, and $K \subseteq X$ a metrizable compact convex set. Let E be the set of extreme points of K. Then for any $x^* \in K$ there is a Radon probability measure μ on K such that x^* is the barycenter of μ and $\mu E = 1$.

proof By 461J, there is a Radon probability measure μ on K such that x^* is the barycenter of μ and $\mu(\frac12(M+M')) = 0$ whenever M, M' are disjoint closed convex subsets of K, writing $\frac12(M+M')$ for $\{\frac12(x+y) : x \in M,\ y \in M'\}$. Now $\mu E = 1$. **P** Let $\mathcal{U}$ be the set of convex open subsets of X. Because the topology of X is locally convex, $\mathcal{U}$ is a base for the topology of X, and $\mathcal{V} = \{K\cap U : U \in \mathcal{U}\}$ is a base for the topology of K (4A2B(a-iv)); because K is compact and metrizable, it is separable (4A2Od), and there

is a countable base $\mathcal{V}_0 \subseteq \mathcal{V}$ (4A2O(a-iii)). Set $\mathcal{M} = \{\overline{V} : V \in \mathcal{V}_0\}$, so that $\mathcal{M}$ is a countable family of closed convex subsets of K.

If $x \in K \setminus E$, then there are distinct y, $z \in K$ such that $x = \frac{1}{2}(y+z)$. Now there must be disjoint M, $M' \in \mathcal{M}$ such that $y \in M$ and $z \in M'$, so that $x \in \frac{1}{2}(M + M')$. Thus

$$K \setminus E \subseteq \bigcup\{\tfrac{1}{2}(M+M') : M,\, M' \in \mathcal{M},\, M \cap M' = \emptyset\}.$$

As $\mathcal{M}$ is countable, $\mu(K \setminus E) = 0$ and $\mu E = 1$, as required. **Q**

461L In the form above, Choquet's theorem really does depend on the metrizability of X (see 461Yb). But there is a version which applies more generally, as follows.

Lemma Let X be a Hausdorff locally convex linear topological space and K a compact convex subset of X. Let $T : X \to \mathbb{R}^{\mathbb{N}}$ be a continuous linear operator. Let E be the set of extreme points of K and x_0 a point of K such that $Tx_0 \notin T[E]$. Then x_0 is expressible as $\frac{1}{2}(y_1 + y_2)$ where y_1, $y_2 \in K$ and $Ty_1 \neq Ty_2$.

proof (a) For each $n \in \mathbb{N}$, set $\gamma_n = \sup_{x \in K} |(Tx)(n)|$, and consider

$$g(x) = \sum_{n=0}^{\infty} \frac{1}{2^n(\gamma_n+1)} |(Tx)(n) - (Tx_0)(n)|$$

for $x \in K$. Then $g : K \to [0, \infty[$ is a continuous convex function and $g^{-1}[\{0\}] = \{x : x \in K,\, Tx = Tx_0\}$, so $g(x) > 0$ for every $x \in E$, while $g(x_0) = 0$. Let M be the closed convex hull of $\{(x, g(x)) : x \in K\}$ in $X \times \mathbb{R}$.

(b) **?** Suppose, if possible, that $(x_0, \alpha) \notin M$ for every $\alpha > 0$. Then for every $n \in \mathbb{N}$ there is a continuous linear functional $h_n : X \times \mathbb{R} \to \mathbb{R}$ such that $h_n(x_0, 2^{-n}) > \sup_{x \in K} h_n(x, g(x))$. Let $f_n \in X^*$, $\beta_n \in \mathbb{R}$ be such that $h_n(x, \alpha) = f_n(x) + \beta_n \alpha$ for every $x \in X$, $\alpha \in \mathbb{R}$; because $h_n(x_0, 2^{-n}) > h_n(x_0, 0)$, $\beta_n > 0$.

Set $Y = \mathbb{R}^{\mathbb{N}} \times \mathbb{R}^{\mathbb{N}}$ and define $S : X \to Y$ by setting $Sx = (Tx, \langle f_n(x)\rangle_{n \in \mathbb{N}})$ for $x \in X$; then S is continuous and linear, so $S[K]$ is compact and convex in Y. Set

$$\tilde{g}(w, z) = \sum_{n=0}^{\infty} \frac{1}{2^n(\gamma_n+1)} |w(n) - (Tx_0)(n)|$$

for $(w, z) \in S[K]$, so that $\tilde{g}$ is a continuous convex function and $g = \tilde{g}S$. Let F be the set of extreme points of $S[K]$. By Choquet's theorem, there is a Radon probability measure ν on $S[K]$ such that Sx_0 is the barycenter of ν and $\nu F = 1$.

For each $n \in \mathbb{N}$, we have

$$f_n(x) + \beta_n g(x) = h_n(x, g(x)) \leq h_n(x_0, 2^{-n}) = f_n(x_0) + 2^{-n}\beta_n$$

for each $x \in K$. So for $(w, z) \in S[K]$ we get

$$z(n) + \beta_n \tilde{g}(w, z) \leq f_n(x_0) + 2^{-n}\beta_n.$$

Integrating with respect to ν, and recalling that $Sx_0 = (Tx_0, \langle f_n(x_0)\rangle_{n \in \mathbb{N}})$ is the barycenter of ν, we get

$$f_n(x_0) + \beta_n \int \tilde{g}\, d\nu \leq f_n(x_0) + 2^{-n}\beta_n,$$

and (because $\beta_n > 0$) $\int \tilde{g}\, d\nu \leq 2^{-n}$. As n is arbitrary, $\int \tilde{g}\, d\nu = 0$.

But $F \subseteq S[E]$ (4A4Gc), and $g(x) > 0$ for every $x \in E$, so $\tilde{g}(w, z) > 0$ for every $(w, z) \in F$. Since $\nu F = 1$, $\int \tilde{g}\, d\nu > 0$, which is impossible. **X**

(c) There is therefore some $\alpha_0 > 0$ such that $(x_0, \alpha_0) \in M$. Of course $L = \{(x, g(x)) : x \in K\}$ is compact (being a continuous image of K), so there is a Radon probability measure λ on L such that (x_0, α_0) is the barycenter of λ (461H). Let μ be the image measure $\lambda\pi_1^{-1}$ on K, where $\pi_1(x, \alpha) = x$; then μ is a Radon probability measure on K, and x_0 is the barycenter of μ (461B). At the same time,

$$\int_K g\, d\mu = \int_L g\pi_1(x, \alpha)\lambda(d(x, \alpha)) = \int_L \alpha\lambda(d(x, \alpha))$$

(because if $(x, \alpha) \in L$ then $\alpha = g(x)$)

$$= \alpha_0 > 0$$

(because $(x,\alpha)\mapsto\alpha$ is a continuous linear functional on $X\times\mathbb{R}$ and (x_0,α_0) is the barycenter of λ). Looking back at the construction of g, there must be some $n\in\mathbb{N}$ such that $\int_K|(Tx)(n)-(Tx_0)(n)|\mu(dx)$ is non-zero.

(d) Since $x\mapsto(Tx)(n)$ is a continuous linear functional, $\int_K(Tx)(n)\mu(dx)=(Tx_0)(n)=\beta$ say, and

$$M_1=\{x:(Tx)(n)\leq\beta\},\quad M_2=\{x:(Tx)(n)>\beta\}$$

must both have non-zero measure. We therefore have Radon probability measures μ_1, μ_2 on K defined by saying that $\mu_1H=\mu(H\cap M_1)/\mu M_1$, $\mu_2H=\mu(H\cap M_2)/\mu M_2$ whenever these are defined. For each i, we have a barycenter y_i' of μ_i; since

$$(Ty_1')(n)=\int_K(Tx)(n)\mu_1(dx)\leq\beta<\int_K(Tx)(n)\mu_2(dx)=(Ty_2')(n),$$

$Ty_1'\neq Ty_2'$. On the other hand, for any $f\in X^*$,

$$f((\mu M_1)y_1'+(\mu M_2)y_2')=\mu M_1\int_K f d\mu_1+\mu M_2\int_K f d\mu_2=\int_K f d\mu=f(x_0),$$

so $x_0=(\mu M_1)y_1'+(\mu M_2)y_2'$.

(e) Thus x_0 is a proper convex combination of y_1' and y_2', which are members of K distinguished by T. There must therefore be distinct y_1, y_2 in the line segment $\Gamma(\{y_1',y_2'\})$ such that $x_0=\frac{1}{2}(y_1+y_2)$, and in this case $Ty_1\neq Ty_2$, as required.

461M Theorem Let X be a Hausdorff locally convex linear topological space and K a compact convex subset of X. Let E be the set of extreme points of K. Then for any x^* in K there is a Baire probability measure μ on K such that x^* is the barycenter of μ and $\mu^*E=1$.

proof (a) By 461J, there is a Radon probability measure $\tilde\mu$ on K such that x^* is the barycenter of $\tilde\mu$ and $\tilde\mu(\frac{1}{2}(M+M'))=0$ whenever M, M' are disjoint closed convex subsets of K. Let μ be the restriction of $\tilde\mu$ to the Baire σ-algebra of K; since $f\restriction K$ is surely Baire measurable for every $f\in X^*$, we have $\int f d\mu=\int f d\tilde\mu=f(x^*)$ for every $f\in X^*$, and x^* is still the barycenter of μ.

(b) The point is that $\tilde\mu Z=0$ for every zero set Z in K which is disjoint from E. **P** Since $Z\subseteq K$ is a closed G_δ set in K, $K\setminus Z$ is expressible as a union $\bigcup_{n\in\mathbb{N}}F_n$ of compact sets. For any $n\in\mathbb{N}$, $z\in Z$ and $y\in F_n$, there is an $f\in X^*$ such that $f(z)\neq f(y)$; since Z and F_n are compact, there is a finite set $\Phi_n\subseteq X^*$ such that whenever $z\in Z$ and $y\in F_n$ there is an $f\in\Phi_n$ such that $f(z)\neq f(y)$. Set $\Phi=\bigcup_{n\in\mathbb{N}}\Phi_n\cup\{0\}$; then Φ is countable; let $\langle f_n\rangle_{n\in\mathbb{N}}$ be a sequence running over Φ, and define $T:X\to\mathbb{R}^{\mathbb{N}}$ by setting $(Tx)(n)=f_n(x)$ for $n\in\mathbb{N}$, $x\in X$. Then T is a continuous linear operator and $T[Z]$ is disjoint from $T[F_n]$ for every $n\in\mathbb{N}$, so $T[Z]$ is disjoint from $T[E]$.

Lemma 461L now tells us that for every $z\in Z$ there are x, $y\in K$ such that $z=\frac{1}{2}(x+y)$ and $Tx\neq Ty$. For $n\in\mathbb{N}$ and $q<q'$ in $\mathbb{Q}$ set $M_{nqq'}=\{x:x\in K,\,f_n(x)\leq q\}$, $M'_{nqq'}=\{x:x\in K,\,f_n(x)\geq q'\}$. Then $M_{nqq'}$ and $M'_{nqq'}$ are disjoint closed convex subsets of K, so $\tilde\mu(\frac{1}{2}(M_{nqq'}+M'_{nqq'}))=0$; but as $Z\subseteq\bigcup_{n\in\mathbb{N},q<q'}\frac{1}{2}(M_{nqq'}+M'_{nqq'})$, $\tilde\mu Z=0$. **Q**

(c) Since μ is inner regular with respect to the zero sets (412D), it follows that $\mu F=0$ whenever $F\in\operatorname{dom}\mu$ and $F\cap E=\emptyset$, so that $\mu^*E=1$, as required.

461N Corollary Let X be a Hausdorff locally convex linear topological space and K a compact convex subset of X, with E its set of extreme points. Then for any x^* in K there is a probability measure ν on E such that x^* is the barycenter of ν. If K is metrizable, we can take ν to be a Radon measure.

proof Take ν to be the subspace measure μ_E, where μ is the Baire measure of 461M or the Radon measure of 461K; then

$$f(x^*)=\int_K f d\mu=\int_E f d\nu$$

for every $f\in X^*$, by 214F.

461O It is a nearly universal rule that when we encounter a compact convex set we should try to identify its extreme points. I look now at some sets which arose naturally in §437.

Proposition Let X be a set, Σ a σ-algebra of subsets of X, and $\phi : X \to X$ a (Σ, Σ)-measurable function. Let M_σ be the L-space of countably additive real-valued functionals on Σ, and $Q \subseteq M_\sigma$ the set of probability measures with domain Σ for which ϕ is inverse-measure-preserving. If $\mu \in Q$, then μ is an extreme point of Q iff ϕ is ergodic with respect to μ.

proof (a) Suppose that ϕ is μ-ergodic, and that $\mu = \frac{1}{2}(\mu_1 + \mu_2)$ where μ_1, $\mu_2 \in Q$. Then $0 \leq \mu_1 E \leq 2\mu E$ for every $E \in \Sigma$, so there is a Σ-measurable $f : X \to [0, 2]$ such that $\mu_1 E = \int_E f d\mu$ for every $E \in \Sigma$ (232F). For $\alpha \geq 0$, set $G_\alpha = \{x : x \in X, f(x) > \alpha\}$. Then, for any $E \in \Sigma$,

$$\mu_1 E = \int f \times \chi E \, d\mu = \int_0^\infty \mu(E \cap G_\alpha) d\alpha$$

where the integral $\int d\alpha$ is taken with respect to Lebesgue measure (252O). We are supposing that $\mu_1 \phi^{-1}[E] = \mu_1 E$ for every $E \in \Sigma$. In particular, for any $\alpha \geq 0$,

$$\begin{aligned}
\alpha\mu G_\alpha + \int_\alpha^\infty \mu G_\beta d\beta &= \int_0^\infty \mu(G_\alpha \cap G_\beta) d\beta = \mu_1 G_\alpha \\
&= \mu_1 \phi^{-1}[G_\alpha] = \int_0^\infty \mu(\phi^{-1}[G_\alpha] \cap G_\beta) d\beta \\
&\leq \alpha\mu\phi^{-1}[G_\alpha] + \int_\alpha^\infty \mu(\phi^{-1}[G_\alpha] \cap G_\beta) d\beta \\
&= \alpha\mu G_\alpha + \int_\alpha^\infty \mu(\phi^{-1}[G_\alpha] \cap G_\beta) d\beta
\end{aligned}$$

because μ also belongs to Q. So

$$\int_\alpha^\infty \mu G_\beta d\beta \leq \int_\alpha^\infty \mu(\phi^{-1}[G_\alpha] \cap G_\beta) d\beta.$$

It follows that $\mu(\phi^{-1}[G_\alpha] \cap G_\beta) = \mu G_\beta$, that is, $G_\beta \setminus \phi^{-1}[G_\alpha]$ is μ-negligible, for almost every $\beta > \alpha$. Take a sequence $\langle \beta_n \rangle_{n \in \mathbb{N}}$ with infimum α such that $G_{\beta_n} \setminus \phi^{-1}[G_\alpha]$ is μ-negligible for every n; then $G_\alpha = \bigcup_{n \in \mathbb{N}} G_{\beta_n}$, so $G_\alpha \setminus \phi^{-1}[G_\alpha]$ is μ-negligible. As $\mu G_\alpha = \mu\phi^{-1}[G_\alpha]$, $G_\alpha \triangle \phi^{-1}[G_\alpha]$ is μ-negligible. Since ϕ is μ-ergodic, μG_α must be 0 or 1 (372J).

As this is true for every α, f must be μ-essentially constant, and $\mu_1 = \mu$. As μ_1 and μ_2 are arbitrary, μ is an extreme point of Q.

(b) Suppose that ϕ is not ergodic. Let $E \in \Sigma$ be such that $\phi^{-1}[E] = E$ and $0 < \mu E < 1$. Set $\alpha = \mu E$, $\beta = 1 - \mu E$ and let μ_1, μ_2 be the uncompleted indefinite-integral measures over μ defined by $\frac{1}{\alpha}\chi E$ and $\frac{1}{\beta}\chi(X \setminus E)$ (234Cc). Then both are probability measures with domain Σ. For any $F \in \Sigma$,

$$\begin{aligned}
\mu_1(\phi^{-1}[F]) &= \frac{1}{\alpha}\mu(E \cap \phi^{-1}[F]) = \frac{1}{\alpha}\mu(\phi^{-1}[E] \cap \phi^{-1}[F]) \\
&= \frac{1}{\alpha}\mu(\phi^{-1}[E \cap F]) = \frac{1}{\alpha}\mu(E \cap F) = \mu_1 F.
\end{aligned}$$

So μ_1 and $\mu_1\phi^{-1}$ agree on Σ and $\mu_1 \in Q$. Similarly, $\mu_2 \in Q$. As neither μ_1 nor μ_2 is equal to μ, μ is not extreme in Q.

461P Corollary Let X be a compact Hausdorff space and $\phi : X \to X$ a continuous function. Let Q_ϕ be the non-empty compact convex set of Radon probability measures μ on X such that ϕ is inverse-measure-preserving for μ, with its narrow topology and the convex structure inherited from its identifications with subsets of $C(X)^*$ and of the L-space of countably additive functionals on the Borel σ-algebra of X (437S). Then the extreme points of Q_ϕ are those for which ϕ is inverse-measure-preserving and ergodic.

proof (a) If $\mu_0 \in Q_\phi$ is not extreme, let $\mathcal{B} = \mathcal{B}(X)$ be the Borel σ-algebra of X, so that ϕ is $(\mathcal{B}, \mathcal{B})$-measurable, and write Q'_ϕ for the set of ϕ-invariant Borel probability measures on X. Then 461O tells us that the extreme points of Q'_ϕ are just the measures for which ϕ is ergodic. If $\mu \in Q_\phi$, then $\mu\restriction\mathcal{B} \in Q'_\phi$, and of course the function $\mu \mapsto \mu\restriction\mathcal{B}$ is injective (416Eb) and preserves convex combinations. So $\mu_0\restriction\mathcal{B}$ is not extreme in Q'_ϕ. By 461O, ϕ is not $\mu_0\restriction\mathcal{B}$-ergodic, and therefore not μ_0-ergodic.

(b) If $\mu_0 \in Q_\phi$ and ϕ is not μ_0-ergodic, let $E \in \operatorname{dom}\mu_0$ be such that $0 < \mu_0 E < 1$ and $\phi^{-1}[E] = E$. Set $\alpha = \mu_0 E$ and $\beta = 1 - \alpha$, and let μ_1, μ_2 be the indefinite-integral measures over μ_0 defined by $\frac{1}{\alpha}\chi E$ and $\frac{1}{\beta}\chi(X \setminus E)$. Then μ_1 is a Radon probability measures on X (416S), so the image measure $\mu_1\phi^{-1}$ is also a Radon measure (418I). The argument of part (b) of the proof of 461O tells us that $\mu_1\phi^{-1}$ agrees with μ_1 on Borel sets, so $\mu_1 = \mu_1\phi^{-1}$ (416Eb) and $\mu_1 \in Q_\phi$. Similarly, $\mu_2 \in Q_\phi$, and $\mu_0 = \alpha\mu_1 + \beta\mu_2$, so μ_0 is not extreme in Q_ϕ.

461X Basic exercises >(a) Let X be a Hausdorff locally convex linear topological space, $C \subseteq X$ a convex set, and $g : C \to \mathbb{R}$ a function. Show that the following are equiveridical: (i) g is convex and lower semi-continuous; (ii) there are a non-empty set $D \subseteq X^*$ and a family $\langle \beta_f \rangle_{f\in D}$ in $\mathbb{R}$ such that $g(x) = \sup_{f\in D} f(x) + \beta_f$ for every $x \in C$. (Compare 233Hb.)

>(b) Let X be a Hausdorff locally convex linear topological space, $K \subseteq X$ a compact convex set, and x an extreme point of K. Let μ be a probability measure on X such that $\mu^* K = 1$ and x is the barycenter of μ. (i) Show that $\{y : y \in K,\ f(y) \neq f(x)\}$ is μ-negligible for every $f \in X^*$. (*Hint*: 461D.) (ii) Show that if μ is a Radon measure then $\mu\{x\} = 1$.

(c) For each $n \in \mathbb{N}$, define $d_n \in \boldsymbol{c}_0$ by saying that $d_n(n) = 1$, $d_n(i) = 0$ if $i \neq n$. Let μ be the point-supported Radon probability measure on $\boldsymbol{c}_0$ defined by saying that $\mu E = \sum_{n=0}^{\infty} 2^{-n-1}\chi E(2^n d_n)$ for every $E \subseteq \boldsymbol{c}_0$. (i) Show that every member of $\boldsymbol{c}_0^*$ is μ-integrable. (*Hint*: $\boldsymbol{c}_0^*$ can be identified with ℓ^1.) (ii) Show that μ has no barycenter in $\boldsymbol{c}_0$.

(d) Let I be an uncountable set, and $X = \{x : x \in \ell^\infty(I), \{i : x(i) \neq 0\} \text{ is countable}\}$. Show that X is a closed linear subspace of $\ell^\infty(I)$. (i) Show that there is a probability measure μ on X such that (α) $\mu\{x : \|x\| \leq 1\}$ is defined and equal to 1 (β) $\mu\{x : x(i) = 1\} = 1$ for every $i \in I$. (ii) Show that $\int f d\mu$ is defined for every $f \in X^*$. (*Hint*: for any $f \in X^\sim$, there is a countable set $J \subseteq X$ such that $f(x) = 0$ whenever $x \restriction J = 0$, so that $f =_{\text{a.e.}} f(\chi J)$.) (iii) Show that μ has no barycenter in X.

>(e) Let X be a complete Hausdorff locally convex linear topological space, and $K \subseteq X$ a compact set. Show that every extreme point of $\overline{\Gamma(K)}$ belongs to K. (*Hint*: show that it cannot be the barycenter of any measure on K which is not supported by a single point.)

>(f) Let X be a Hausdorff locally convex linear topological space, and $K \subseteq X$ a metrizable compact set. Show that $\overline{\Gamma(K)}$ is metrizable. (*Hint*: we may suppose that X is complete, so that $\overline{\Gamma(K)}$ is compact. Show that $\overline{\Gamma(K)}$ is a continuous image of the space P of Radon probability measures on K, and use 437Ra.)

(g) Let X be a Hausdorff locally convex linear topological space and $K \subseteq X$ a compact set. Show that the Baire σ-algebra of K is just the subspace σ-algebra induced by the cylindrical σ-algebra of X. (*Hint*: disjoint closed subsets of K can be separated by finite subsets of X^*.)

>(h) Let X be a Hausdorff locally convex linear topological space, and $K \subseteq X$ a compact convex set; let E be the set of extreme points of K. Let $\langle f_n \rangle_{n\in\mathbb{N}}$ be a sequence in X^* such that (i) $\sup_{x\in K, n\in\mathbb{N}} |f_n(x)|$ is finite (ii) $\lim_{n\to\infty} f_n(x) = 0$ for every $x \in E$. Show that $\lim_{n\to\infty} f_n(x) = 0$ for every $x \in K$.

>(i) Let X be a Hausdorff locally convex linear topological space, and $K \subseteq X$ a metrizable compact convex set. Show that the set E of extreme points of K is a G_δ set, therefore Polish. Show that the algebra of Borel subsets of K is just the subspace algebra of the cylindrical σ-algebra of X.

(j) Let X be a Hausdorff locally convex linear topological space, and $K \subseteq X$ a compact set. Let us say that a point x of K is **extreme** if the only Radon probability measure on K with barycenter x is the one for which $\{x\}$ has measure 1. (Cf. 461Xb.) (i) Show that if X is complete, then $x \in X$ is an extreme point of K iff it is an extreme point of $\overline{\Gamma(K)}$. (ii) Writing E for the set of extreme points of K, show that any point of K is the barycenter of some probability measure on E. (iii) Show that if K is metrizable then E is a G_δ subset of K and any point of K is the barycenter of some Radon probability measure on E.

(k) Let X be a set, Σ a σ-algebra of subsets of X, and P the set of probability measures with domain Σ, regarded as a convex subset of the linear space of countably additive functionals on Σ. Show that $\mu \in P$ is an extreme point in P iff it takes only the values 0 and 1.

(l) Let X be a set, Σ a σ-algebra of subsets of X, $\phi : X \to X$ a (Σ, Σ)-measurable function and M_σ the L-space of countably additive functionals with domain Σ. (i) Show that the set $V = \{\mu : \mu \in M_\sigma, \mu\phi^{-1}[E] = \mu E \text{ for every } E \in \Sigma\}$ is a norm-closed Riesz subspace of M_σ, so is an L-space in its own right. (ii) Let Q_ϕ be the set of probability measures in V. Show that if μ, ν are distinct extreme points of Q_ϕ then there is an $E \in \Sigma$ which is negligible for one and conegligible for the other. (*Hint*: show that $\sup_{n\in\mathbb{N}} \mu \wedge n\nu = 0$ and apply 326I to $\mu - \nu$.)

>(m) Set $S^1 = \{z : z \in \mathbb{C}, |z| = 1\}$, and let $w \in S^1$ be such that $w^n \neq 1$ for any integer 1. Define $\phi : S^1 \to S^1$ by setting $\phi(z) = wz$ for every $z \in S^1$. Show that the only Radon probability measure on S^1 for which ϕ is inverse-measure-preserving is the Haar probability measure μ of S^1. (*Hint*: use 281N to show that $\lim_{n\to\infty} \frac{1}{n+1} \sum_{k=0}^{n} f(w^k z) = \int f d\mu$ for every $f \in C(S^1)$; now put 461P and 372I together.)

(n) Set $\phi(x) = 2\min(x, 1-x)$ for $x \in [0,1]$ (cf. 372Xm). Show that there are many point-supported Radon measures on $[0,1]$ for which ϕ is inverse-measure-preserving.

461Y Further exercises (a) Let X be a Hausdorff locally convex linear topological space. (i) Show that if $M_0, \ldots, M_n$ are non-empty compact convex subsets of X with empty intersection, then there is a continuous convex function $g : X \to \mathbb{R}$ such that $g(\sum_{i=0}^{n} \alpha_i x_i) < \sum_{i=0}^{n} \alpha_i g(x_i)$ whenever $x_i \in M_i$ and $\alpha_i > 0$ for every $i \leq n$. (ii) Show that if $K \subseteq X$ is compact and $x^* \in \overline{\Gamma(K)}$ then there is a Radon probability measure μ on K, with barycenter x^*, such that $\mu(\alpha_0 M_0 + \ldots + \alpha_n M_n) = 0$ whenever $M_0, \ldots, M_n$ are compact convex sets with empty intersection, $\alpha_i \geq 0$ for every $i \leq n$, and $\sum_{i=0}^{n} \alpha_i = 1$.

(b) In $\mathbb{R}^{[0,2[}$ let K be the set of those functions u such that (α) $0 \leq u(s) \leq u(t) \leq 1$ whenever $0 \leq s \leq t \leq 1$ (β) $|u(t+1)| \leq u(s') - u(s)$ whenever $0 \leq s < t < s' \leq 1$. (i) Show that K is a compact convex set. (ii) Show that the set E of extreme points of K is just the set of functions of the types $\mathbf{0}$, $\chi[0,1]$, $\chi[s,1] \pm \chi\{1+s\}$ and $\chi\,]s,1] \pm \chi\{1+s\}$ for $0 < s < 1$. (iii) Set $w(s) = s$ for $s \in [0,1]$, 0 for $s \in]1,2[$. Show that if μ is any Radon probability measure on K with barycenter w then $\mu E = 0$.

(c) Let G be a topological group. Show that it is amenable iff whenever X is a Hausdorff linear topological space, and $\bullet$ is a continuous action of G on X such that $x \mapsto a\bullet x$ is a linear operator for every $a \in G$, and $K \subseteq X$ is a compact convex set such that $a\bullet x \in K$ for every $a \in G$ and $x \in K$, then there is an $x \in K$ such that $a\bullet x = x$ for every $a \in G$. Use this to simplify parts of the proof of 449C. (*Hint*: 493B.)

(d) Let X be a set, Σ a σ-algebra of subsets of X, and Φ a set of (Σ, Σ)-measurable functions from X to itself. Let M_σ be the L-space of countably additive real-valued functionals on Σ, and $Q \subseteq M_\sigma$ the set of probability measures with domain Σ for which every member of Φ is inverse-measure-preserving. (i) Show that if $\mu \in Q$, then μ is an extreme point of Q iff $\mu E \in \{0,1\}$ whenever $E \in \Sigma$ and $\mu(E \triangle \phi^{-1}[E]) = 0$ for every $\phi \in \Phi$. (ii) Show that if $\mu \in Q$ and Φ is countable and commutative, then μ is an extreme point of Q iff $\mu E \in \{0,1\}$ whenever $E \in \Sigma$ and $E = \phi^{-1}[E]$ for every $\phi \in \Phi$.

(e) Let X be a non-empty Hausdorff space, and define $\phi : X^{\mathbb{N}} \to X^{\mathbb{N}}$ by setting $\phi(x)(n) = x(n+1)$ for $x \in X^{\mathbb{N}}$, $n \in \mathbb{N}$. Let Q_ϕ be the set of Radon measures on $X^{\mathbb{N}}$ for which ϕ is inverse-measure-preserving. Show that a Radon probability measure λ on $X^{\mathbb{N}}$ is an extreme point of Q_ϕ iff it is a Radon product measure $\mu^{\mathbb{N}}$ for some Radon probability measure μ on X.

461 Notes and comments The results above are a little unusual in that we have studied locally convex spaces for several pages without encountering two topologies on the same space more than once (461I). In fact some of the most interesting properties of measures on locally convex spaces concern their relationships with strong and weak topologies, but I defer these ideas to later parts of the chapter. For the moment, we just have the basic results (i) affirming that barycenters exist (461D, 461E, 461G) (ii) that points can be represented as barycenters (461H, 461K, 461M). The last two can be thought of as refinements of the

Kreĭn-Milman theorem. Any compact convex set K (in a locally compact Hausdorff space) is the closed convex hull of the set E of its extreme points. By 461N, given $x \in K$, we can actually find a measure on E with barycenter x; and if K is metrizable we can do this with a Radon measure. Of course the second part of 461N is a straightforward consequence of the first, because in the metrizable case E is a Borel set, the cylindrical σ-algebra (on K or E) is the Borel algebra, and any Borel probability measure on E must be tight (461Xi, 433Ca). But I do not know of any proof of 461N which does not pass through 461K.

Kreĭn's theorem (461I) is a fundamental result in the theory of linear topological spaces. The proof here, using the Riesz representation theorem and vague topologies, is a version of the standard one (e.g., Bourbaki 87, II.4.1), written out to be a little heavier in the measure theory and a little lighter in the topological linear space theory than is usual. There are of course proofs which do not use measure theory.

In §437 I have already looked at an archetypal special case of 461H and 461M. If X is a compact Hausdorff space and P the compact convex set of Radon probability measures on X with the vague topology, then the set of extreme points of P can be identified with $\Delta = \{\delta(x) : x \in X\}$, where $\delta(x)$ is the Radon probability measure concentrated at the point x (437P, 437Xo). If we think of P as a subset of $C(X)^*$ with the weak* topology, so that the dual of the linear topological space $C(X)^*$ can be identified with $C(X)$, then any $\mu \in P$ is the barycenter of a Baire measure ν on Δ. In fact (because Δ here is compact) μ is the barycentre of a Radon measure on Δ, and this is just the image measure $\mu\delta^{-1}$.

Another class of examples arising in §437 is explored in 461O-461P, 461Xk-461Xn and 461Yd-461Ye. It is when we have an explicit listing of the extreme points, as in 461Yb and 461Ye, that we begin to feel that we understand a compact convex set.

462 Pointwise compact sets of continuous functions

In preparation for the main work of this chapter, beginning in the next section, I offer a few pages on spaces of continuous functions under their 'pointwise' topologies (462Ab). There is an extensive general theory of such spaces, described in Arkhangel'skiĭ 92; here I present only those fragments which seem directly relevant to the theory of measures on normed spaces and spaces of functions. In particular, I star the paragraphs 462B-462D, which are functional analysis rather than measure theory. They are here because although this material is well known, and may be found in many places, I think that the ideas, as well as the results, are essential for any understanding of measures on linear topological spaces.

Measure theory enters the section in the proof of 462E, in the form of an application of the Riesz representation theorem, though 462E itself remains visibly part of functional analysis. In the rest of the section, however, we come to results which are pure measure theory. For (countably) compact spaces X, the Radon measures on $C(X)$ are the same for the pointwise and norm topologies (462G). This fact has extensive implications for the theory of separately continuous functions (462I) and for the theory of convex hulls in linear topological spaces (462J).

462A Definitions (a) A regular Hausdorff space X is **angelic** if whenever A is a subset of X which is relatively countably compact in X, then (i) its closure $\overline{A}$ is compact (ii) every point of $\overline{A}$ is the limit of a sequence in A.

(A **Fréchet-Urysohn** space is a topological space in which, for any set A, every point of the closure of A is a limit of a sequence in A. So (ii) here may be written as 'every compact subspace of X is a Fréchet-Urysohn space'.)

(b) If X is any set and A a subset of $\mathbb{R}^X$, then the topology of **pointwise convergence** on A is that inherited from the usual product topology of $\mathbb{R}^X$; that is, the coarsest topology on A for which the map $f \mapsto f(x) : A \to \mathbb{R}$ is continuous for every $x \in X$. I shall commonly use the symbol $\mathfrak{T}_p$ for such a topology. In this context, I will say that a sequence or filter is **pointwise convergent** if it is convergent for the topology of pointwise convergence. Note that if A is a linear subspace of $\mathbb{R}^X$ then $\mathfrak{T}_p$ is a linear space topology on A (4A4Ba).

***462B Theorem** (PRYCE 71) Let X be a topological space such that there is a sequence $\langle X_n\rangle_{n\in\mathbb{N}}$ of countably compact subsets of X, covering X, with the property that a function $f : X \to \mathbb{R}$ is continuous whenever $f\restriction X_n$ is continuous for every $n \in \mathbb{N}$. Then the space $C(X)$ of continuous real-valued functions on X is angelic in its topology of pointwise convergence.

proof Of course $C(X)$ is regular and Hausdorff under $\mathfrak{T}_p$, because $\mathbb{R}^X$ is, so we need attend only to the rest of the definition in 462Aa. Let $A \subseteq C(X)$ be relatively countably compact for $\mathfrak{T}_p$.

(a) Since $\{f(x) : f \in A\}$, being a continuous image of A, must be relatively countably compact in $\mathbb{R}$ (4A2G(f-iv)), therefore relatively compact (4A2Le), for every $x \in X$, the closure $\overline{A}$ of A in $\mathbb{R}^X$ is compact, by Tychonoff's theorem.

? Suppose, if possible, that $\overline{A} \not\subseteq C(X)$; let $g \in \overline{A}$ be a discontinuous function. By the hypothesis of the theorem, there is an $n \in \mathbb{N}$ such that $g\restriction X_n$ is not continuous; take $x^* \in X_n$ such that $g\restriction X_n$ is discontinuous at x^*. Let $\epsilon > 0$ be such that for every neighbourhood U of x^* in X_n there is a point $x \in U$ such that $|g(x) - g(x^*)| \geq \epsilon$.

Choose sequences $\langle f_i\rangle_{i\in\mathbb{N}}$ in A, $\langle x_i\rangle_{i\in\mathbb{N}}$ in X_n as follows. Given $\langle f_i\rangle_{i<m}$ and $\langle x_i\rangle_{i<m}$, choose $x_m \in X_n$ such that $|f_i(x_m) - f_i(x^*)| \leq 2^{-m}$ for every $i < m$ and $|g(x^*) - g(x_m)| \geq \epsilon$. Now choose $f_m \in A$ such that $|f_m(x^*) - g(x^*)| \leq 2^{-m}$ and $|f_m(x_i) - g(x_i)| \leq 2^{-m}$ for every $i \leq m$. Continue.

At the end of the induction, take a cluster point x of $\langle x_i\rangle_{i\in\mathbb{N}}$ in X_n and a cluster point f of $\langle f_i\rangle_{i\in\mathbb{N}}$ in $C(X)$. Because $|f_i(x_m) - f_i(x^*)| \leq 2^{-m}$ whenever $i < m$, $f_i(x) = f_i(x^*)$ for every i, and $f(x) = f(x^*)$. Because $|f_m(x^*) - g(x^*)| \leq 2^{-m}$ for every m, $f(x^*) = g(x^*)$. Because $|f_m(x_i) - g(x_i)| \leq 2^{-m}$ whenever $i \leq m$, $f(x_i) = g(x_i)$ for every i, $|g(x^*) - f(x_i)| \geq \epsilon$ for every i, and $|g(x^*) - f(x)| \geq \epsilon$; but this is impossible, because $f(x) = f(x^*) = g(x^*)$. **X**

Thus the compact set $\overline{A} \subseteq C(X)$ is the closure of A in $C(X)$, and A is relatively compact in $C(X)$.

(b) Now take any $g \in \overline{A}$. There are countable sets $D \subseteq X$, $B \subseteq A$ such that

whenever $I \subseteq B \cup \{g\}$ is finite, $n \in \mathbb{N}$, $\epsilon > 0$ and $x \in X_n$, there is a $y \in D \cap X_n$ such that $|f(y) - f(x)| \leq \epsilon$ for every $f \in I$;

whenever $J \subseteq D$ is finite and $\epsilon > 0$ there is an $f \in B$ such that $|f(x) - g(x)| \leq \epsilon$ for every $x \in J$.

P For any finite set $I \subseteq \mathbb{R}^X$ and $n \in \mathbb{N}$, the set $Q_{In} = \{\langle f(x)\rangle_{f\in I} : x \in X_n\}$ is a subset of the separable metric space $\mathbb{R}^I$, so is itself separable, and there is a countable dense set $D_{In} \subseteq X_n$ such that $Q'_{In} = \{\langle f(x)\rangle_{f\in I} : x \in D_{In}\}$ is dense in Q_{In}. Similarly, because $g \in \overline{A}$, we can choose for any finite set $J \subseteq X$ a sequence $\langle f_{Ji}\rangle_{i\in\mathbb{N}}$ in A such that $\lim_{i\to\infty} f_{Ji}(x) = g(x)$ for every $x \in J$.

Now construct $\langle D_m\rangle_{m\in\mathbb{N}}$, $\langle B_m\rangle_{m\in\mathbb{N}}$ inductively by setting

$$D_m = \bigcup\{D_{In} : n \in \mathbb{N},\ I \subseteq \{g\} \cup \textstyle\bigcup_{i<m} B_i \text{ is finite}\},$$

$$B_m = \{f_{Jk} : k \in \mathbb{N},\ J \subseteq \textstyle\bigcup_{i<m} D_i \text{ is finite}\}.$$

At the end of the induction, set $D = \bigcup_{m\in\mathbb{N}} D_m$ and $B = \bigcup_{m\in\mathbb{N}} B_m$. Since the construction clearly ensures that $\langle D_m\rangle_{m\in\mathbb{N}}$ and $\langle B_m\rangle_{m\in\mathbb{N}}$ are non-decreasing sequences of countable sets, D and B are countable, and we shall have $D_{In} \subseteq D$ whenever $n \in \mathbb{N}$ and $I \subseteq B \cup \{g\}$ is finite, while $f_{Ji} \in B$ whenever $i \in \mathbb{N}$ and $J \subseteq D$ is finite. Thus we have suitable sets D and B. **Q**

By the second condition on D and B, there must be a sequence $\langle f_i\rangle_{i\in\mathbb{N}}$ in B such that $g(x) = \lim_{i\to\infty} f_i(x)$ for every $x \in D$. In fact $g(y) = \lim_{i\to\infty} f_i(y)$ for every $y \in X$. **P?** Otherwise, there is an $\epsilon > 0$ such that $J = \{i : |g(y) - f_i(y)| \geq \epsilon\}$ is infinite. Let n be such that $y \in X_n$. For each $m \in \mathbb{N}$, $I_m = \{f_i : i \leq m\}$ is a finite subset of B, so there is an $x_m \in D_{I_m n}$ such that $|f(x_m) - f(y)| \leq 2^{-m}$ for every $f \in I_m \cup \{g\}$. Let $x^* \in X_n$ be a cluster point of $\langle x_m\rangle_{m\in\mathbb{N}}$, and $h \in C(X)$ a cluster point of $\langle f_i\rangle_{i\in J}$. Then

because $g(x) = \lim_{i\to\infty} f_i(x)$ for every $x \in D$, $g(x_m) = h(x_m)$ for every $m \in \mathbb{N}$, and $g(x^*) = h(x^*)$;

because $|g(y) - f_i(y)| \geq \epsilon$ for every $i \in J$, $|g(y) - h(y)| \geq \epsilon$;

because $|f_i(x_m) - f_i(y)| \leq 2^{-m}$ whenever $i \leq m$, $f_i(x^*) = f_i(y)$ for every $i \in \mathbb{N}$, and $h(x^*) = h(y)$;

because $|g(x_m) - g(y)| \leq 2^{-m}$ for every m, $g(x^*) = g(y)$;

but this means that $g(y) = g(x^*) = h(x^*) = h(y) \neq g(y)$, which is absurd. **XQ**

So $g = \lim_{i\to\infty} f_i$ for $\mathfrak{T}_p$. As g is arbitrary, A has both properties required in 462Aa; as A is arbitrary, $C(X)$ is angelic.

Remark For a slight strengthening of this result, see 462Ya.

***462C Proposition** (PRYCE 71) Let $(X, \mathfrak{T})$ be an angelic regular Hausdorff space.
(a) Any subspace of X is angelic.
(b) If $\mathfrak{S}$ is a regular topology on X finer than $\mathfrak{T}$, then $\mathfrak{S}$ is angelic.
(c) Any countably compact subset of X is compact and sequentially compact.

proof (a) Let Y be any subset of X. Then of course the subspace topology on Y is regular and Hausdorff. If $A \subseteq Y$ is relatively countably compact in Y, then A is relatively countably compact in X, so $\overline{A}$, the closure of A in X, is compact. Now if $x \in \overline{A}$, there is a sequence $\langle x_n\rangle_{n\in\mathbb{N}}$ in A converging to x; but $\langle x_n\rangle_{n\in\mathbb{N}}$ must have a cluster point in Y, and (because $\mathfrak{T}$ is Hausdorff) this cluster point can only be x. Accordingly $\overline{A} \subseteq Y$ and is the closure of A in Y. Thus A is relatively compact in Y. Moreover, any point of $\overline{A}$ is the limit of a sequence in A. As A is arbitrary, Y is angelic.

(b) By hypothesis, $\mathfrak{S}$ is regular, and it is Hausdorff because it is finer than $\mathfrak{T}$. Now suppose that $A \subseteq X$ is $\mathfrak{S}$-relatively countably compact. Because the identity map from $(X, \mathfrak{S})$ to $(X, \mathfrak{T})$ is continuous, A is $\mathfrak{T}$-relatively countably compact (4A2G(f-iv)), and the $\mathfrak{T}$-closure $\overline{A}$ of A is $\mathfrak{T}$-compact.

Let $\mathcal{F}$ be any ultrafilter on X containing A. Then $\mathcal{F}$ has a $\mathfrak{T}$-limit $x \in X$. **?** If $\mathcal{F}$ is not $\mathfrak{S}$-convergent to x, there is an $H \in \mathfrak{S}$ such that $x \in H$ and $X \setminus H \in \mathcal{F}$, so that $A \setminus H \in \mathcal{F}$. Now x belongs to the $\mathfrak{T}$-closure of $A \setminus H$, because $A \setminus H \in \mathcal{F}$ and $\mathcal{F}$ is $\mathfrak{T}$-convergent to x; because $\mathfrak{T}$ is angelic, there is a sequence $\langle x_n\rangle_{n\in\mathbb{N}}$ in $A \setminus H$ which $\mathfrak{T}$-converges to x. But now $\langle x_n\rangle_{n\in\mathbb{N}}$ has a $\mathfrak{S}$-cluster point x'. x' must also be a $\mathfrak{T}$-cluster point of $\langle x_n\rangle_{n\in\mathbb{N}}$, so $x' = x$; but every x_n belongs to the $\mathfrak{S}$-closed set $X \setminus H$, so $x' \notin H$, which is impossible. **X**

Thus every ultrafilter on X containing A is $\mathfrak{S}$-convergent. Because $\mathfrak{S}$ is regular, the $\mathfrak{S}$-closure $\tilde{A}$ of A is $\mathfrak{S}$-compact (3A3De).

Again because $\mathfrak{S}$ is finer than $\mathfrak{T}$, and $\mathfrak{T}$ is Hausdorff, the two topologies must agree on $\tilde{A} = \overline{A}$. But now every point of $\overline{A}$ is the $\mathfrak{T}$-limit of a sequence in A, so every point of $\tilde{A}$ is the $\mathfrak{S}$-limit of a sequence in A. As A is arbitrary, $\mathfrak{S}$ is angelic.

(c) If $K \subseteq X$ is countably compact, then of course it is relatively countably compact in its subspace topology, so (being angelic) must be compact in its subspace topology. If $\langle x_n\rangle_{n\in\mathbb{N}}$ is a sequence in K, let x be any cluster point of $\langle x_n\rangle_{n\in\mathbb{N}}$. If $\{n : x_n = x\}$ is infinite, then this immediately provides us with a subsequence converging to x. Otherwise, take n such that $x \neq x_i$ for $i \geq n$. Since $x \in \overline{\{x_i : i \geq n\}}$, and $\{x_i : i \geq n\}$ is relatively countably compact, there is a sequence $\langle y_i\rangle_{i\in\mathbb{N}}$ in $\{x_i : i \geq n\}$ converging to x. The topology of X being Hausdorff, $\{y_i : i \in \mathbb{N}\}$ must be infinite, and $\langle y_i\rangle_{i\in\mathbb{N}}$, $\langle x_i\rangle_{i\in\mathbb{N}}$ have a common subsequence which converges to x. As $\langle x_i\rangle_{i\in\mathbb{N}}$ is arbitrary, K is sequentially compact.

***462D Theorem** Let U be any normed space. Then it is angelic in its weak topology.

proof Write X for the unit ball of the dual space U^*, with its weak* topology. Then X is compact (3A5F). We have a natural map $u \mapsto \hat{u} : U \to \mathbb{R}^X$ defined by setting $\hat{u}(x) = x(u)$ for $x \in X$, $u \in U$. By the definition of the weak* topology, $\hat{u} \in C(X)$ for every $u \in U$. The weak topology of U is normally defined in terms of all functionals $u \mapsto f(u)$, for $f \in U^*$; but as every member of U^* is a scalar multiple of some $x \in X$, we can equally regard the weak topology of U as defined just by the functionals $u \mapsto x(u) = \hat{u}(x)$, for $x \in X$. But this means that the map $u \mapsto \hat{u}$ is a homeomorphism between U, with its weak topology, and its image $\widehat{U}$ in $C(X)$, with the topology of pointwise convergence.

Since $C(X)$ is $\mathfrak{T}_p$-angelic (462B), so is $\widehat{U}$ (462Ca), and U is angelic in its weak topology.

462E Theorem Let X be a locally compact Hausdorff space, and $C_0(X)$ the Banach lattice of continuous real-valued functions on X which vanish at infinity (436I). Write $\mathfrak{T}_p$ for the topology of pointwise convergence on $C_0(X)$.

(i) A sequence $\langle u_n\rangle_{n\in\mathbb{N}}$ in $C_0(X)$ is weakly convergent to $u \in C_0(X)$ iff it is $\mathfrak{T}_p$-convergent and norm-bounded.

(ii) A subset K of $C_0(X)$ is weakly compact iff it is norm-bounded and $\mathfrak{T}_p$-compact.

proof (a) Since all the maps $f \mapsto f(x)$, where $x \in X$, are bounded linear functionals on $C_0(X)$, the $\mathfrak{T}_p$ is coarser than the weak topology $\mathfrak{T}_s$; so a $\mathfrak{T}_s$-convergent sequence is $\mathfrak{T}_p$-convergent, and a $\mathfrak{T}_s$-compact set is $\mathfrak{T}_p$-compact.

(b) If $K \subseteq C_0(X)$ is $\mathfrak{T}_s$-compact, then $f[K] \subseteq \mathbb{R}$ must be compact, therefore bounded, for every $f \in C_0(X)^*$; by the Uniform Boundedness Theorem (3A5Hb), K is norm-bounded. Applying this to $\{u\} \cup \{u_n : n \in \mathbb{N}\}$, we see that any $\mathfrak{T}_s$-convergent sequence $\langle u_n \rangle_{n\in\mathbb{N}}$ with limit u is norm-bounded.

(c) Suppose that $\langle u_n \rangle_{n\in\mathbb{N}}$ is norm-bounded and $\mathfrak{T}_p$-convergent to u. By Lebesgue's Dominated Convergence Theorem, $\lim_{n\to\infty} \int u_n d\mu = \int u\, d\mu$ for every totally finite Radon measure μ on X. But by the Riesz Representation Theorem (in the form 436K), this says just that $\lim_{n\to\infty} f(u_n) = f(u)$ for every positive linear functional f on $C_0(X)$. Since every member of $C_0(X)^*$ is expressible as the difference of two positive linear functionals (356Dc), $\lim_{n\to\infty} f(u_n) = f(u)$ for every $f \in U^*$, that is, $\langle u_n \rangle_{n\in\mathbb{N}}$ is $\mathfrak{T}_s$-convergent to u.

Putting this together with (a) and (b), we see that (i) is true.

(d) Now suppose that $K \subseteq C_0(X)$ is norm-bounded and $\mathfrak{T}_p$-compact. Then it is $\mathfrak{T}_p$-closed, therefore $\mathfrak{T}_s$-closed. Because $\mathfrak{T}_p$ is angelic (462B), any sequence $\langle u_n \rangle_{n\in\mathbb{N}}$ in K has a $\mathfrak{T}_p$-convergent subsequence (462Cc), which is also $\mathfrak{T}_s$-convergent, by (c). This means that K is (relatively) countably compact in $C_0(X)$ for the topology $\mathfrak{T}_s$. Since $\mathfrak{T}_s$ is angelic (462D), the $\mathfrak{T}_s$-closure of K is $\mathfrak{T}_s$-compact; but this is just K, so K is $\mathfrak{T}_s$-compact, as claimed.

462F Proposition Let X be a countably compact topological space. Then a subset of $C_b(X)$ is weakly compact iff it is norm-bounded and compact for the topology $\mathfrak{T}_p$ of pointwise convergence.

proof I should perhaps begin by remarking that, because X is countably compact, every continuous real-valued function on X is bounded (4A2G(f-v)), so that we have a natural norm $\|\ \|_\infty$ on $C(X) = C_b(X)$ (354Hb). A weakly compact subset of $C(X)$ is norm-bounded and $\mathfrak{T}_p$-compact by the same arguments as in (a)-(b) of the proof of 462E.

Suppose that $K \subseteq C_b(X)$ is norm-bounded and $\mathfrak{T}_p$-compact. We have a natural map $x \mapsto \hat{x} : X \to \mathbb{R}^K$ defined by writing $\hat{x}(u) = u(x)$ for every $u \in K$, $x \in X$. By the definition of $\mathfrak{T}_p$, $\hat{x} \in C(K)$ for every $x \in X$, if we interpret $C(K)$ as the space of $\mathfrak{T}_p$-continuous real-valued functions on K; and $x \mapsto \hat{x} : X \to C(K)$ is continuous for the given topology on X and the topology of pointwise convergence on $C(K)$ because $K \subseteq C(X)$. It follows that $Z = \{\hat{x} : x \in X\}$ is countably compact for the topology of pointwise convergence on $C(K)$ (4A2G(f-vi)). But now Z must be actually compact for the topology of pointwise convergence on $C(K)$, by 462B.

Next, consider the natural map $u \mapsto \hat{u} : K \to \mathbb{R}^Z$ defined by setting $\hat{u}(f) = f(u)$ for $f \in Z$, $u \in K$. Just as in the last paragraph, this is a continuous function from K to $C(Z)$, if we give K, Z and $C(Z)$ their topologies of pointwise convergence. So $L = \{\hat{u} : u \in K\}$ is compact for the topology of pointwise convergence on $C(Z)$. Moreover, it is norm-bounded, because

$$\sup_{\phi\in L} \|\phi\|_\infty = \sup_{u\in K, f\in Z} |\hat{u}(f)| = \sup_{u\in K, x\in X} |u(x)| = \sup_{u\in K} \|u\|_\infty$$

is finite. So 462E tells us that L is weakly compact in $C(Z)$. (Note that $C(Z) = C_0(Z)$ because Z is compact.)

Now we have an operator $T : C(Z) \to \mathbb{R}^X$ defined by setting

$$T(\phi)(x) = \phi(\hat{x})$$

for $\phi \in C(Z)$, $x \in X$. Because $x \mapsto \hat{x} : X \to Z$ is continuous, $T\phi \in C(X)$ for every $\phi \in C(Z)$, and of course T is norm-preserving. So $T[L]$ is weakly compact in $C(X)$ (2A5If). But if $u \in K$ and $x \in X$,

$$(T\hat{u})(x) = \hat{u}(\hat{x}) = \hat{x}(u) = u(x),$$

so $T\hat{u} = u$. Accordingly $K = T[L]$, and K is weakly compact, as claimed.

462G Theorem Let X be a countably compact topological space. Then the totally finite Radon measures on $C(X)$ are the same for the topology of pointwise convergence and the norm topology.

proof (a) As in 462F, $C(X) = C_b(X)$ is a Banach space under its norm $\|\ \|_\infty$. Write $\mathfrak{T}_p$ for the topology of pointwise convergence on $C(X)$ and $\mathfrak{T}_\infty$ for the norm topology. Because $\mathfrak{T}_p \subseteq \mathfrak{T}_\infty$, every totally finite $\mathfrak{T}_\infty$-Radon measure is $\mathfrak{T}_p$-Radon (418I).

(b) For the rest of the proof, therefore, I take a totally finite $\mathfrak{T}_p$-Radon measure μ on $C(X)$ and seek to prove that it is $\mathfrak{T}_\infty$-Radon. By 418L, applied to the identity map from $(C(X), \mathfrak{T}_\infty)$ to $(C(X), \mathfrak{T}_p)$, it will be enough to show that whenever $E \in \operatorname{dom}\mu$ and $\mu E > 0$ there is some $\mathfrak{T}_\infty$-compact set K such that $\mu(E \cap K) > 0$.

(c) I show first that if $E \in \operatorname{dom}\mu$ and $\mu E > 0$, and $\epsilon > 0$, there is some $g \in C(X)$ such that $\mu(E \cap B(g,\epsilon)) > 0$, where $B(g,\epsilon) = \{f : \|f - g\|_\infty \leq \epsilon\}$. **P?** Suppose, if possible, otherwise. Let $K \subseteq E$ be a non-empty $\mathfrak{T}_p$-compact set such that $\mu K > 0$. Since all the balls $B(0,k)$ are $\mathfrak{T}_p$-closed, we may suppose that K is $\|\ \|_\infty$-bounded, therefore weakly compact (462F). Choose $\langle K_n\rangle_{n\in\mathbb{N}}$ and $\langle f_n\rangle_{n\in\mathbb{N}}$ as follows. $K_0 = K$. Given that $K_n \subseteq E$ is non-negligible and $\mathfrak{T}_p$-compact, and that $\langle f_i\rangle_{i<n}$ is a finite sequence in $C(X)$, then the convex hull Γ_n of $\{f_i : i < n\}$ is $\mathfrak{T}_\infty$-compact, so there is a finite set $D_n \subseteq \Gamma_n$ such that for every $g \in \Gamma_n$ there is a $g' \in D_n$ such that $\|g - g'\|_\infty \leq \frac{1}{2}\epsilon$. Now

$$H_n = \{f : \|f - g\|_\infty > \epsilon \text{ for every } g \in D_n\}$$

is a $\mathfrak{T}_p$-open set and $E \setminus H_n$ is negligible, so $\mu(K_n \cap H_n) > 0$ and we can find a non-negligible $\mathfrak{T}_p$-closed set $K_{n+1} \subseteq K_n \cap H_n$; choose $f_n \in K_{n+1}$. Continue.

At the end of the induction, let f^* be any cluster point of $\langle f_n\rangle_{n\in\mathbb{N}}$ for the weak topology on $C(X)$. The set $\Gamma = \bigcup_{n\in\mathbb{N}} \Gamma_n$ is convex, so its norm-closure $\overline{\Gamma}$ is also convex (2A5Eb), therefore closed for the weak topology (3A5Ee), and contains f^*. So there is a $g \in \Gamma$ such that $\|f^* - g\|_\infty \leq \frac{1}{2}\epsilon$. Now there is some n such that $g \in \Gamma_n$. Let $g' \in D_n$ be such that $\|g - g'\|_\infty \leq \frac{1}{2}\epsilon$, so that $\|f^* - g'\| \leq \epsilon$. Since $f_i \in K_{n+1}$ for every $i \geq n$, and K_{n+1} is $\mathfrak{T}_p$-closed, therefore closed for the weak topology, $f^* \in K_{n+1} \subseteq H_n$, and $\|f^* - g'\| > \epsilon$, which is impossible. **XQ**

(d) What this means is that if we take $\mathcal{K}_n$ to be the family of subsets of $C(X)$ which can be covered by finitely many balls of radius at most 2^{-n}, then μ is inner regular with respect to $\mathcal{K}_n$ (see 412Aa), and therefore with respect to $\mathcal{K} = \bigcap_{n\in\mathbb{N}} \mathcal{K}_n$ (412Ac). But $\mathcal{K}$ is just the set of subsets of $C(X)$ which are totally bounded for the norm-metric ρ on $C(X)$. By 412Ac again, μ must be inner regular with respect to the family of $\mathfrak{T}_p$-closed ρ-totally bounded sets, which are surely $\mathfrak{T}_\infty$-closed therefore ρ-complete and $\mathfrak{T}_\infty$-compact. By 418L, μ is $\mathfrak{T}_\infty$-Radon.

462H Corollary Let X be a countably compact Hausdorff space, and give $C(X)$ its topology of pointwise convergence. If μ is any Radon measure on $C(X)$, it is inner regular with respect to the family of compact metrizable subsets of $C(X)$.

proof In the language of 462G, μ is inner regular with respect to the family of $\mathfrak{T}_\infty$-compact sets; but as $\mathfrak{T}_p \subseteq \mathfrak{T}_\infty$, the two topologies agree on all such sets, and they are compact and metrizable for $\mathfrak{T}_p$.

462I Proposition Let X be a topological space, Y a Hausdorff space, $f : X \times Y \to \mathbb{R}$ a bounded separately continuous function, and ν a totally finite Radon measure on Y. Set $\phi(x) = \int f(x,y)\nu(dy)$ for every $x \in X$. Then $\phi\restriction C$ is continuous for any relatively countably compact set $C \subseteq X$.

proof (a) To begin with, suppose that X itself is countably compact. For $y \in Y$, set $u_y(x) = f(x,y)$ for every $x \in X$. Then every u_y is continuous, because f is continuous in the first variable, and $y \mapsto u_y : Y \to C(X)$ is continuous, if we give $C(X)$ the topology $\mathfrak{T}_p$ of pointwise convergence, because f is continuous in the second variable. We therefore have a $\mathfrak{T}_p$-Radon image measure μ on $C(X)$, by 418I.

By 462G, μ is a Radon measure for the norm topology of $C(X)$. Now recall that f is bounded. If $|f(x,y)| \leq M$ for all $x \in X$, $y \in Y$, then $\|u_y\|_\infty \leq M$ for every $y \in Y$, and the ball $B(0,M)$ in $C(X)$ is μ-conegligible. By 461E, applied to the subspace measure on $B(0,M)$, μ has a barycenter h in $C(X)$. Now we can compute h by the formulae

$$h(x) = \int g(x)\mu(dg)$$

(because $g \mapsto g(x)$ belongs to $C(X)^*$)

$$= \int u_y(x)\nu(dy)$$

(by 235I)

$$= \int f(x,y)\nu(dy) = \phi(x),$$

for every $x \in X$. So $\phi = h$ is continuous.

(b) For the general result, we have only to apply (a) to $f\restriction C$ for each countably compact $C \subseteq X$.

462J Corollary Let X be a topological space such that

whenever $h \in \mathbb{R}^X$ is such that $h\restriction C$ is continuous for every relatively countably compact $C \subseteq X$, then h is continuous.

Write $\mathfrak{T}_p$ for the topology of pointwise convergence on $C(X)$. Let $K \subseteq C(X)$ be a $\mathfrak{T}_p$-compact set such that $\sup_{h\in K, x\in C} |h(x)|$ is finite for any countably compact set $C \subseteq X$. Then the $\mathfrak{T}_p$-closed convex hull of K, taken in $C(X)$, is $\mathfrak{T}_p$-compact.

proof The closed convex hull $\overline{\Gamma(K)}$ of K, taken in $\mathbb{R}^X$, is closed and included in a product of closed bounded intervals, therefore compact. If $h \in \overline{\Gamma(K)}$, then there is a Radon probability measure μ on K such that h is the barycenter of μ (461H), so that $h(x) = \int f(x)\mu(df)$ for every $x \in X$. If $C \subseteq X$ is countably compact, the map $(x, f) \mapsto f(x) : C \times K \to \mathbb{R}$ is separately continuous, because $K \subseteq C(X)$ is being given the topology of pointwise convergence, and is bounded by hypothesis. So 462I tells us that $x \mapsto \int f(x)\mu(df) : C \to \mathbb{R}$ is continuous, that is, that $h\restriction C$ is continuous. By the hypothesis on X here, h is continuous.

Thus the $\mathfrak{T}_p$-compact set $\overline{\Gamma(K)}$ is included in $C(X)$, and must be the closed convex hull of K in $C(X)$.

Remark The hypothesis

whenever $h \in \mathbb{R}^X$ is such that $h\restriction C$ is continuous for every relatively countably compact $C \subseteq X$, then h is continuous

is clumsy, but seems the best way to cover the large number of potential applications of the ideas here. Besides the obvious case of countably compact spaces X, we have all first-countable spaces (for which, of course, the other hypotheses can be relaxed, as in 462Xc), and all k-spaces. (A **k-space** is a topological space X such that a set $G \subseteq X$ is open iff $G \cap K$ is relatively open in K for every compact set $K \subseteq X$; see Engelking 89, 3.3.18 *et seq.* In particular, all locally compact spaces are k-spaces.) Perhaps the most important case of all is when X is the the dual U^* of a complete locally convex Hausdorff linear topological space U, endowed with the topology $\mathfrak{T}_s(U^*, U)$, so that U, with its weak topology $\mathfrak{T}_s(U, U^*)$, can be regarded as a linear subspace of $C(X)$ with its topology of pointwise convergence (see 4A4Ch).

462X Basic exercises (a) (i) Show that $\mathbb{R}$, with the right-facing Sorgenfrey topology, is angelic. (ii) Show that any metrizable space is angelic. (iii) Show that the one-point compactification of an angelic locally compact Hausdorff space is angelic. (iv) Find a first-countable regular Hausdorff space which is not angelic.

>(b) Let X be any countably compact topological space. Show that a norm-bounded sequence in $C_b(X)$ which is pointwise convergent is weakly convergent.

(c) Let X be a first-countable topological space, (Y, T, ν) a totally finite measure space, and $f : X \times Y \to \mathbb{R}$ a bounded function such that $y \mapsto f(x, y)$ is measurable for every $x \in X$, and $x \mapsto f(x, y)$ is continuous for almost every $y \in Y$. Show that $x \mapsto \int f(x, y)\nu(dy)$ is continuous.

(d) Give an example of a $\mathfrak{T}_p$-compact subset K of $C([0, 1])$ such that the convex hull of K is not relatively compact in $C([0, 1])$.

462Y Further exercises (a) Let X be a topological space such that there is a sequence $\langle X_n\rangle_{n\in\mathbb{N}}$ of countably compact subsets of X, covering X, with the property that a function $f : X \to \mathbb{R}$ is continuous whenever $f\restriction X_n$ is continuous for every $n \in \mathbb{N}$. Let $\mathfrak{T}_p$ be the topology of pointwise convergence on $C(X)$. Show that, for a set $K \subseteq C(X)$, the following are equiveridical: (i) $\phi[K]$ is bounded for every $\mathfrak{T}_p$-continuous function $\phi : C(X) \to \mathbb{R}$; (ii) whenever $\langle f_n\rangle_{n\in\mathbb{N}}$ is a sequence in K and $A \subseteq X$ is countable, there is a cluster point of $\langle f_n\restriction A\rangle_{n\in\mathbb{N}}$ in $C(A)$ for the topology of pointwise convergence on $C(A)$; (iii) K is relatively compact in $C(X)$ for $\mathfrak{T}_p$. (See Asanov & Velichko 81.)

(b) Let U be a metrizable locally convex linear topological space. Show that it is angelic in its weak topology. (*Hint*: start with the case in which U is complete, using Grothendieck's theorem and the full strength of 462B, with $X = U^*$.)

(c) In 462I, show that the conclusion remains valid for any totally finite τ-additive topological measure ν on Y which is inner regular with respect to the relatively countably compact subsets of Y.

(d) Show that if X is any compact topological space (more generally, any topological space such that X^n is Lindelöf for every $n \in \mathbb{N}$), then $C(X)$, with its topology of pointwise convergence, is countably tight.

462Z Problem Let K be a compact Hausdorff space. Is $C(K)$, with the topology of pointwise convergence, necessarily a pre-Radon space?

462 Notes and comments The theory of pointwise convergence in spaces of continuous functions is intimately connected with the theory of separately continuous functions of two variables. For if X and Y are topological spaces, and $f : X \times Y \to \mathbb{R}$ is any separately continuous function, then we have natural maps $x \mapsto f_x : X \to C(Y)$ and $y \mapsto f^y : Y \to C(X)$, writing $f_x(y) = f^y(x) = f(x, y)$, which are continuous if $C(X)$ and $C(Y)$ are given their topologies of pointwise convergence; and if X is a topological space and Y is any subset of $C(X)$ with its topology of pointwise convergence, the map $(x, y) \mapsto y(x) : X \times Y \to \mathbb{R}$ is separately continuous. I include a back-and-forth shuffle between $C(X)$ and separately continuous functions in 462G-462I-462J largely as a demonstration of the principle that all the theorems here can be expressed in both languages.

462Yb is a compendium of Šmulian's theorem with part of Eberlein's theorem; 462E and 462J can be thought of as the centre of Krein's theorem. There are many alternative routes to these results, which may be found in KÖTHE 69 or GROTHENDIECK 92. In particular, 462E can be proved without using measure theory; see, for instance, FREMLIN 74, A2F.

Topological spaces homeomorphic to compact subsets of $C(X)$, where X is some compact space and $C(X)$ is given its topology of pointwise convergence, are called **Eberlein compacta**; see 467O-467P.

A positive answer to A.Bellow's problem (463Za below) would imply a positive answer to 462Z; so if the continuum hypothesis, for instance, is true, then $C(K)$ is pre-Radon in its topology of pointwise convergence for any compact space K.

463 $\mathfrak{T}_p$ and $\mathfrak{T}_m$

We are now ready to start on the central ideas of this chapter with an investigation of sets of measurable functions which are compact for the topology of pointwise convergence. Because 'measurability' is, from the point of view of this topology on $\mathbb{R}^X$, a rather arbitrary condition, we are looking at compact subsets of a topologically irregular subspace of $\mathbb{R}^X$; there are consequently relatively few of them, and (under a variety of special circumstances, to be examined later in the chapter and also in Volume 5) they have some striking special properties.

The presentation here is focused on the relationship between the two natural topologies on any space of measurable functions, the 'pointwise' topology $\mathfrak{T}_p$ and the topology $\mathfrak{T}_m$ of convergence in measure (463A). In this section I begin with results which apply to any σ-finite measure space (463B-463G) before turning to some which apply to perfect measure spaces (463H-463K) – in particular, to Lebesgue measure. These lead to some interesting properties of separately continuous functions (463L-463M).

463A Notation Let (X, Σ, μ) be a measure space, and $\mathcal{L}^0 = \mathcal{L}^0(\Sigma)$ the space of all Σ-measurable functions from X to $\mathbb{R}$, so that $\mathcal{L}^0$ is a linear subspace of $\mathbb{R}^X$. On $\mathcal{L}^0$ we shall be concerned with two very different topologies. The first is the topology $\mathfrak{T}_p$ of pointwise convergence (462Ab); the second is the topology $\mathfrak{T}_m$ of (local) convergence in measure (245Ab). Both are linear space topologies. **P** For $\mathfrak{T}_p$ I have already noted this in 462Ab. For $\mathfrak{T}_m$, repeat the argument of 245D; $\mathfrak{T}_m$ is defined by the functionals $f \mapsto \int_F \min(1, |f|)d\mu$, where $\mu F < \infty$, and these satisfy the criterion of 2A5B. **Q** $\mathfrak{T}_p$ is Hausdorff (3A3Id) and locally convex (4A4Ce); only in exceptional circumstances is either true of $\mathfrak{T}_m$. However, $\mathfrak{T}_m$ can easily

be pseudometrizable (if, for instance, μ is σ-finite, as in 245Eb), while $\mathfrak{T}_p$ is not, except in nearly trivial cases.

Associated with the topology of pointwise convergence on $\mathbb{R}^X$ is the usual topology of $\mathcal{P}X$ (definition: 4A2A); the map $\chi : \mathcal{P}X \to \mathbb{R}^X$ is a homeomorphism between $\mathcal{P}X$ and its image $\{0,1\}^X \subseteq \mathbb{R}^X$.

$\mathfrak{T}_m$ is intimately associated with the topology of convergence in measure on $L^0 = L^0(\mu)$ (§245). A subset of $\mathcal{L}^0$ is open for $\mathfrak{T}_m$ iff it is of the form $\{f : f^\bullet \in G\}$ for some open set $G \subseteq L^0$; consequently, a subset K of $\mathcal{L}^0$ is compact, or separable, for $\mathfrak{T}_m$ iff $\{f^\bullet : f \in K\}$ is compact or separable for the topology of convergence in measure on L^0.

It turns out that the identity map from $(\mathcal{L}^0, \mathfrak{T}_p)$ to $(\mathcal{L}^0, \mathfrak{T}_m)$ is sequentially continuous (463B). Only in nearly trivial cases is it actually continuous (463Xa(i)), and it is similarly rare for the reverse map from $(\mathcal{L}^0, \mathfrak{T}_m)$ to $(\mathcal{L}^0, \mathfrak{T}_p)$ to be continuous (463Xa(ii)). If, however, we relativise both topologies to a $\mathfrak{T}_p$-compact subset of $\mathcal{L}^0$, the situation becomes very different, and there are many important cases in which the topologies are comparable.

463B Lemma Let (X, Σ, μ) be a measure space, and $\mathcal{L}^0$ the space of Σ-measurable real-valued functions on X. Then every pointwise convergent sequence in $\mathcal{L}^0$ is convergent in measure to the same limit.

proof 245Ca.

463C Proposition (Ionescu Tulcea 73) Let (X, Σ, μ) be a measure space, and $\mathcal{L}^0$ the space of Σ-measurable real-valued functions on X. Write $\mathfrak{T}_p$, $\mathfrak{T}_m$ for the topologies of pointwise convergence and convergence in measure on $\mathcal{L}^0$; for $A \subseteq \mathcal{L}^0$, write $\mathfrak{T}_{pA}$, $\mathfrak{T}_{mA}$ for the corresponding subspace topologies.

(a) If $A \subseteq \mathcal{L}^0$ and $\mathfrak{T}_{pA}$ is metrizable, then the identity map from A to itself is $(\mathfrak{T}_{pA}, \mathfrak{T}_{mA})$-continuous.

(b) Suppose that μ is semi-finite. Then, for any $A \subseteq \mathcal{L}^0$, $\mathfrak{T}_{mA}$ is Hausdorff iff whenever f, g are distinct members of A the set $\{x : f(x) \neq g(x)\}$ is non-negligible.

(c) Suppose that $K \subseteq \mathcal{L}^0$ is such that $\mathfrak{T}_{pK}$ is compact and metrizable. Then $\mathfrak{T}_{pK} = \mathfrak{T}_{mK}$ iff $\mathfrak{T}_{mK}$ is Hausdorff.

(d) Suppose that μ is σ-finite, and that $K \subseteq \mathcal{L}^0$ is $\mathfrak{T}_p$-sequentially compact. Then $\mathfrak{T}_{pK} = \mathfrak{T}_{mK}$ iff $\mathfrak{T}_{mK}$ is Hausdorff, and in this case $\mathfrak{T}_{pK}$ is compact and metrizable.

(e) Suppose that $K \subseteq \mathcal{L}^0$ is such that $\mathfrak{T}_{pK}$ is compact and metrizable. Then whenever $\epsilon > 0$ and $E \in \Sigma$ is a non-negligible measurable set, there is a non-negligible measurable set $F \subseteq E$ such that $|f(x) - f(y)| \leq \epsilon$ whenever $f \in K$ and $x, y \in F$.

proof (a) All we need is to remember that sequentially continuous functions from metrizable spaces are continuous (4A2Ld), and apply 463B.

(b) $\mathfrak{T}_{mA}$ is Hausdorff iff for any distinct f, $g \in A$ there is a measurable set F of finite measure such that $\int_F \min(1, |f-g|)d\mu > 0$, that is, $\mu\{x : x \in F, f(x) \neq g(x)\} > 0$; because μ is semi-finite, this happens iff $\mu\{x : f(x) \neq g(x)\} > 0$.

(c) If $\mathfrak{T}_{pK} = \mathfrak{T}_{mK}$ then of course $\mathfrak{T}_{mK}$ is Hausdorff, because $\mathfrak{T}_{pK}$ is. If $\mathfrak{T}_{mK}$ is Hausdorff then the identity map $(K, \mathfrak{T}_{pK}) \to (K, \mathfrak{T}_{mK})$ is an injective function from a compact space to a Hausdorff space and (by (a)) is continuous, therefore a homeomorphism, so the two topologies are equal.

(d) If $\mathfrak{T}_{pK} = \mathfrak{T}_{mK}$ then $\mathfrak{T}_{mK}$ must be Hausdorff, just as in (c). So let us suppose that $\mathfrak{T}_{mK}$ is Hausdorff. Note that, by 245Eb, the topology of convergence in measure on L^0 is metrizable; in terms of $\mathcal{L}^0$, this says just that the topology of convergence in measure on $\mathcal{L}^0$ is pseudometrizable. So $\mathfrak{T}_{mK}$ is Hausdorff and pseudometrizable, therefore metrizable (4A2La).

We are told that any sequence in K has a $\mathfrak{T}_{pK}$-convergent subsequence. But this subsequence is now $\mathfrak{T}_{mK}$-convergent (463B), so $\mathfrak{T}_{mK}$ is sequentially compact; being metrizable, it is compact (4A2Lf). Moreover, the same is true of any $\mathfrak{T}_{pK}$-closed subset of K, so every $\mathfrak{T}_{pK}$-closed set is $\mathfrak{T}_{mK}$-compact, therefore $\mathfrak{T}_{mK}$-closed. Thus the identity map from $(K, \mathfrak{T}_{mK})$ to $(K, \mathfrak{T}_{pK})$ is continuous. Since $\mathfrak{T}_{mK}$ is compact and $\mathfrak{T}_{pK}$ is Hausdorff, the two topologies are equal; and, in particular, $\mathfrak{T}_{pK}$ is compact and metrizable.

(e) Let ρ be a metric on K inducing the topology $\mathfrak{T}_{pK}$. Let $D \subseteq K$ be a countable dense set. For each $n \in \mathbb{N}$, set

$$G_n = \{x : |f(x) - g(x)| \leq \tfrac{1}{3}\epsilon \text{ whenever } f, g \in D \text{ and } \rho(f,g) \leq 2^{-n}\}.$$

Because D is countable, G_n is measurable. Now $\bigcup_{n\in\mathbb{N}} G_n = X$. **P?** If $x \in X \setminus \bigcup_{n\in\mathbb{N}} G_n$, then for each $n \in \mathbb{N}$ we can find f_n, $g_n \in D$ such that $\rho(f_n, g_n) \leq 2^{-n}$ and $|f_n(x) - g_n(x)| \geq \frac{1}{3}\epsilon$. Because K is compact, there is a strictly increasing sequence $\langle n_k\rangle_{k\in\mathbb{N}}$ such that $\langle f_{n_k}\rangle_{k\in\mathbb{N}}$ and $\langle g_{n_k}\rangle_{k\in\mathbb{N}}$ are both convergent to f, g say. Now

$$\rho(f,g) = \lim_{k\to\infty} \rho(f_{n_k}, g_{n_k}) = 0, \quad |f(x) - g(x)| = \lim_{k\to\infty} |f_{n_k}(x) - g_{n_k}(x)| \geq \tfrac{1}{3}\epsilon,$$

so $f = g$ while $f(x) \neq g(x)$, which is impossible. **XQ**

There is therefore some $n \in \mathbb{N}$ such that $\mu(E \cap G_n) > 0$. Since K, being compact, is totally bounded for ρ, there is a finite set $D' \subseteq D$ such that every member of D is within a distance of 2^{-n} of some member of D'. Now there is a measurable set $F \subseteq E \cap G_n$ such that $\mu F > 0$ and $|g(x) - g(y)| \leq \frac{1}{3}\epsilon$ whenever $g \in D'$ and x, $y \in F$. So $|f(x) - f(y)| \leq \epsilon$ whenever $f \in D$ and x, $y \in F$. But as D is dense in K, $|f(x) - f(y)| \leq \epsilon$ whenever $f \in K$ and x, $y \in F$, as required.

463D Proposition Let (X, Σ, μ) be a measure space, and $\mathcal{L}^0$ the space of Σ-measurable real-valued functions on X. Write $\mathfrak{T}_p$, $\mathfrak{T}_m$ for the topologies of pointwise convergence and convergence in measure on $\mathcal{L}^0$. Suppose that $K \subseteq \mathcal{L}^0$ is $\mathfrak{T}_p$-compact and that there is no $\mathfrak{T}_p$-continuous surjection from any closed subset of K onto ω_1+1 with its order topology. Then the identity map from $(K, \mathfrak{T}_p)$ to $(K, \mathfrak{T}_m)$ is continuous.

proof (a) It is worth noting straight away that $\xi \mapsto \chi\xi : \omega_1 + 1 \to \{0,1\}^{\omega_1}$ is a homeomorphism between $\omega_1 + 1$ and a subspace of $\{0,1\}^{\omega_1}$. So our hypothesis tells us that there is no continuous surjection from any closed subset of K onto $\{0,1\}^{\omega_1}$, and therefore none onto $\{0,1\}^A$ for any uncountable A.

(b) For the moment, fix on a sequence $\langle f_n\rangle_{n\in\mathbb{N}}$ in K and a set $E \in \Sigma$ of finite measure. Set $q(x) = \max(1, 2\sup_{n\in\mathbb{N}} |f_n(x)|)$ for each $x \in X$. For any infinite $I \subseteq \mathbb{N}$, set

$$g_I = \sup_{n\in\mathbb{N}} \inf_{i\in I, i\geq n} f_i, \quad h_I = \inf_{n\in\mathbb{N}} \sup_{i\in I, i\geq n} f_i;$$

because $\sup_{f\in K} |f(x)|$ is surely finite for each $x \in X$, g_I and h_I are defined in $\mathcal{L}^0$, and $g_I \leq h_I$. For $f \in \mathcal{L}^0$ set $\tau'(f) = \int_E \min(1, |f|/q)$, and for $I \in [\mathbb{N}]^\omega$ (the set of infinite subsets of $\mathbb{N}$) set $\Delta(I) = \tau'(h_I - g_I)$. Since $h_I - g_I \leq q$, $\Delta(I) = \int_E (h_I - g_I)/q$. If I, $J \in [\mathbb{N}]^\omega$ and $J \setminus I$ is finite, then $g_I \leq g_J \leq h_J \leq h_I$, so $\Delta(J) \leq \Delta(I)$, with equality only when $g_I = g_J$ a.e. on E and $h_I = h_J$ a.e. on E.

(i) There is a $J \in [\mathbb{N}]^\omega$ such that $\Delta(I) = \Delta(J)$ for every $I \in [J]^\omega$. **P** For $J \in [\mathbb{N}]^\omega$, set $\underline{\Delta}(J) = \inf\{\Delta(I) : I \in [J]^\omega\}$. Choose $\langle I_n\rangle_{n\in\mathbb{N}}$ in $[\mathbb{N}]^\omega$ inductively in such a way that $I_{n+1} \subseteq I_n$ and $\Delta(I_{n+1}) \leq \underline{\Delta}(I_n) + 2^{-n}$ for every n. If we now set

$$J = \{\min\{i : i \in I_n, i \geq n\} : n \in \mathbb{N}\},$$

$J \subseteq \mathbb{N}$ will be an infinite set and $J \setminus I_n$ is finite for every n. If $I \in [J]^\omega$ then, for every n,

$$\Delta(J) \leq \Delta(I_{n+1}) \leq \underline{\Delta}(I_n) + 2^{-n} \leq \Delta(I_n \cap I) + 2^{-n} = \Delta(I) + 2^{-n};$$

as n is arbitrary, $\underline{\Delta}(J) = \Delta(J)$, as required. **Q**

Now for any $I \in [J]^\omega$ we have $\Delta(I) = \Delta(J)$, so that $g_I = g_J$ a.e. on E and $h_I = h_J$ a.e. on E.

(ii) Now $\Delta(J) = 0$. **P?** Otherwise, $F = \{x : x \in E, g_J(x) < h_J(x)\}$ has positive measure. Set $K_0 = \bigcap_{n\in\mathbb{N}} \overline{\{f_i : i \in J, i \geq n\}}$, the closure being taken for $\mathfrak{T}_p$, so that K_0 is $\mathfrak{T}_p$-compact. Let $\mathcal{A}$ be the family of sets $A \subseteq F$ such that whenever L, $M \subseteq A$ are finite and disjoint there is an $f \in K_0$ such that $f(x) = g_J(x)$ for $x \in L$ and $f(x) = h_J(x)$ for $x \in M$. Then $\mathcal{A}$ has a maximal member A_0 say. If we define $\phi : \mathcal{L}^0 \to [0,1]^{A_0}$ by setting $\phi(f)(x) = \min(h_J(x), \max(f(x), g_J(x)))/(h_J(x) - g_J(x))$ for $x \in A_0$ and $f \in \mathcal{L}^0$, $\phi[K_0]$ is a compact subset of $[0,1]^{A_0}$, and whenever L, $M \subseteq A_0$ are finite there is a $g \in \phi[K_0]$ such that $g(x) = 0$ for $x \in L$ and $g(x) = 1$ for $x \in M$. This means that $\phi[K_0] \cap \{0,1\}^{A_0}$ is dense in $\{0,1\}^{A_0}$ and must therefore be the whole of $\{0,1\}^{A_0}$. So $\{0,1\}^{A_0}$ is a continuous image of a closed subset of K.

By (a), A_0 is countable. For each pair L, M of disjoint finite subsets of A_0, we have a cluster point f_{LM} of $\langle f_j\rangle_{j\in J}$ such that $f_{LM}(x) = g_J(x)$ for $x \in L$ and $f_{LM}(x) = h_J(x)$ for $x \in M$. Let $I(L,M)$ be an infinite subset of J such that $\lim_{i\to\infty, i\in I(L,M)} f_i(x) = f_{LM}(x)$ for every $x \in A_0$. Then $g_{I(L,M)} = g_J$ and $h_{I(L,M)} = h_J$ almost everywhere on E. Because $\mu F > 0$ and A_0 has only countably many finite subsets,

there is a $y \in F$ such that $g_{I(L,M)}(y) = g_J(y)$ and $h_{I(L,M)}(y) = h_J(y)$ whenever L and M are disjoint finite subsets of A_0.

What this means is that if L and M are disjoint finite subsets of A_0, then there are infinite sets I', $I'' \subseteq I(L,M)$ such that $\lim_{i\to\infty, i\in I'} f_i(y) = g_J(y)$ and $\lim_{i\to\infty, i\in I''} f_i(y) = h_J(y)$; so that there are f', $f'' \in K_0$ such that

$$f'(x) = g_J(x) \text{ for } x \in L \cup \{y\}, \quad f'(x) = h_J(x) \text{ for } x \in M,$$

$$f''(x) = g_J(x) \text{ for } x \in L, \quad f''(x) = h_J(x) \text{ for } x \in M \cup \{y\}.$$

But this means that $A_0 \cup \{y\} \in \mathcal{A}$; and A_0 was chosen to be maximal. **XQ**

(iii) So $\Delta(J) = 0$ and $g_J = h_J$ almost everywhere on E. But if we enumerate J in ascending order as $\langle n_i\rangle_{i\in\mathbb{N}}$, $g_J = \liminf_{i\to\infty} f_{n_i}$ and $h_J = \limsup_{i\to\infty} f_{n_i}$, so $\langle f_{n_i}\rangle_{i\in\mathbb{N}}$ converges almost everywhere on E.

Thus we see that for every sequence in K, and every set of finite measure, there is a subsequence converging almost everywhere on that set.

(c) ? Suppose, if possible, that the identity map from $(K, \mathfrak{T}_p)$ to $(K, \mathfrak{T}_m)$ is not continuous at $f_0 \in K$. Then there are an $E \in \Sigma$, of finite measure, and an $\epsilon > 0$ such that $C = \{f : f \in K, \tau_E(f - f_0) \geq \epsilon\}$ meets every $\mathfrak{T}_p$-neighbourhood of f, where $\tau_E(f) = \int_E \min(1, |f|)$ for every $f \in \mathcal{L}^0$, and there is an ultrafilter $\mathcal{F}$ on $\mathcal{L}^0$ which contains C and converges to f_0 for $\mathfrak{T}_p$. Consider the map $\psi : \mathcal{L}^0 \to L^0(\mu_E)$, where μ_E is the subspace measure on E, defined by setting $\psi(f) = (f\restriction E)^\bullet$ for $f \in \mathcal{L}^0$. We know from (b) that every sequence in K has a subsequence convergent almost everywhere on E, so every sequence in $\psi[K]$ has a subsequence which is convergent for the topology of convergence in measure on $L^0(\mu_E)$. Since this is metrizable, $\psi[K]$ is relatively compact in $L^0(\mu_E)$ (4A2Le), and the image filter $\psi[[\mathcal{F}]]$ has a limit $v \in L^0(\mu_E)$. Let $f_1 \in \mathcal{L}^0$ be such that $\psi(f_1) = v$.

For any countable set $A \subseteq X$ there is a $g \in C$ such that $g\restriction A = f_0\restriction A$ and $g = f_1$ almost everywhere on E. **P** If $X = \emptyset$ this is trivial, so we may, if necessary, enlarge A by one point so that it is not empty. Let $\langle x_n\rangle_{n\in\mathbb{N}}$ be a sequence running over A. Then for each $n \in \mathbb{N}$ the set

$$\{g : g \in C, |g(x_i) - f_0(x_i)| \leq 2^{-n} \text{ for every } i \leq n, \tau_E(g, f_1) \leq 2^{-n}\}$$

belongs to $\mathcal{F}$, so is not empty; take g_n in this set. Let $g \in K$ be any cluster point of $\langle g_n\rangle_{n\in\mathbb{N}}$. Since $\langle g_n\rangle_{n\in\mathbb{N}}$ converges to f_1 almost everywhere on E, $g = f_1$ a.e. on E. Since $\tau_E(g_n - f_0) \geq \epsilon$ for every n, $\tau_E(g - f_0) \geq \epsilon$ and $g \in C$. Since $\langle g_n(x_i)\rangle_{n\in\mathbb{N}}$ converges to $f_0(x_i)$ for every i, $g\restriction A = f_0\restriction A$. So we have the result. **Q**

In particular, there is a $g \in C$ such that $g =_{\text{a.e.}} f_1$, so $F = \{x : x \in E, f_0(x) \neq f_1(x)\}$ has non-zero measure. Now choose $\langle g_\xi\rangle_{\xi<\omega_1}$ in K and $\langle x_\xi\rangle_{\xi<\omega_1}$ in F inductively so that

$$g_\xi \in C, \quad g_\xi = f_1 \text{ almost everywhere on } E, \; g_\xi(x_\eta) = f_0(x_\eta) \text{ for } \eta < \xi$$

(choosing g_ξ),

$$x_\xi \in F, \quad g_\eta(x_\xi) = f_1(x_\xi) \text{ for } \eta < \xi$$

(choosing x_ξ). If we now set $A = \{x_\xi : \xi < \omega_1\}$,

$$K_1 = \textstyle\bigcap_{\xi<\eta<\omega_1} \{f : f \in K, \text{ either } f(x_\xi) = f_0(x_\xi) \text{ or } f(x_\xi) = f(x_\eta) = f_1(x_\eta)\},$$

then K_1 is a closed subset of K containing every g_ξ and also f_0. But if we look at $\{f\restriction A : f \in K_1\}$, this is homeomorphic to $\omega_1 + 1$; which is supposed to be impossible. **X**

So we conclude that the identity map from $(K, \mathfrak{T}_p)$ to $(K, \mathfrak{T}_m)$ is continuous.

463E Corollary Let (X, Σ, μ) be a measure space, and $\mathcal{L}^0$ the space of Σ-measurable real-valued functions on X. Write $\mathfrak{T}_p$, $\mathfrak{T}_m$ for the topologies of pointwise convergence and convergence in measure on $\mathcal{L}^0$. Suppose that $K \subseteq \mathcal{L}^0$ is compact and countably tight for $\mathfrak{T}_p$. Then the identity map from $(K, \mathfrak{T}_p)$ to $(K, \mathfrak{T}_m)$ is continuous. If $\mathfrak{T}_m$ is Hausdorff on K, the two topologies coincide on K.

proof Since $\omega_1 + 1$ is not countably tight (the top point ω_1 is not in the closure of any countable subset of ω_1), $\omega_1 + 1$ is not a continuous image of any closed subset of K (4A2Kb), and we can apply 463D to see that the identity map is continuous. It follows at once that if $\mathfrak{T}_m$ is Hausdorff on K, then the topologies coincide.

463F Theorem (IONESCU TULCEA 74) Let (X, Σ, μ) be a σ-finite measure space, and K a convex set of measurable functions from X to $\mathbb{R}$ such that (i) K is compact for the topology $\mathfrak{T}_p$ of pointwise convergence (ii) $\{x : f(x) \neq g(x)\}$ is not negligible for any distinct $f, g \in K$. Then K is metrizable for $\mathfrak{T}_p$, which agrees with the topology of convergence in measure on K.

proof (a) Let $\langle f_n \rangle_{n\in\mathbb{N}}$ be a sequence in K. Then it has a pointwise convergent subsequence. **P** Because K is compact, we surely have $\sup_{f\in K} |f(x)| < \infty$ for every $x \in X$, so that $q_0 = \chi X + \sup_{n\in\mathbb{N}} |f_n|$ is defined in $\mathbb{R}^X$, and is measurable. Let $\langle X_k \rangle_{k\in\mathbb{N}}$ be a sequence of measurable sets of finite measure covering X, and set

$$q_1 = \textstyle\sum_{k=0}^{\infty} \frac{1}{2^k(1+\mu X_k)} \chi X_k,$$

so that q_1 is a strictly positive measurable function and is square-integrable.

Set $K' = \{f \times q_1/q_0 : f \in K\}$, so that K' is another convex pointwise compact set of measurable functions, this time all dominated by q_1, so that $K' \subseteq \mathcal{L}^2(\mu)$. Setting $g_n = f_n \times q_1/q_0$, the sequence $\langle g_n^\bullet \rangle_{n\in\mathbb{N}}$ of equivalence classes is a norm-bounded sequence in the Hilbert space $L^2 = L^2(\mu)$. It therefore has a weakly convergent subsequence $\langle g^\bullet_{n(i)} \rangle_{i\in\mathbb{N}}$ say (4A4Kb), with limit v.

? Suppose, if possible, that $\langle f_{n(i)} \rangle_{i\in\mathbb{N}}$ is not pointwise convergent. Then there must be some $x_0 \in X$ such that $\liminf_{i\to\infty} f_{n(i)}(x_0) < \limsup_{i\to\infty} f_{n(i)}(x_0)$; let $\alpha < \beta$ in $\mathbb{R}$ be such that $I = \{i : f_{n(i)}(x_0) \leq \alpha\}$, $I' = \{i : f_{n(i)}(x_0) \geq \beta\}$ are both infinite. In this case v belongs to the weak closures of both $D = \{g^\bullet_{n(i)} : i \in I\}$ and $D' = \{g^\bullet_{n(i)} : i \in I'\}$. It must therefore belong to the *norm* closures of their convex hulls $\Gamma(D)$, $\Gamma(D')$ (4A4Ed). Accordingly we can find $v_n \in \Gamma(D)$, $v'_n \in \Gamma(D')$ such that $\|v - v_n\|_2 \leq 3^{-n}$, $\|v - v'_n\|_2 \leq 3^{-n}$ for every $n \in \mathbb{N}$.

Setting $A = \{f_{n(i)} : i \in I\}$, $A' = \{f_{n(i)} : i \in I'\}$, we see that there must be $h_n \in \Gamma(A)$, $h'_n \in \Gamma(A')$ such that $v_n = (h_n \times q_1/q_0)^\bullet$, $v'_n = (h'_n \times q_1/q_0)^\bullet$ for every $n \in \mathbb{N}$. Now if $g : X \to \mathbb{R}$ is a measurable function such that $g^\bullet = v$, and $\tilde{h} = g \times q_0/q_1$, we have

$$\textstyle\int |g - (h_n \times q_1/q_0)|^2 \leq 9^{-n},$$

$$\begin{aligned}\mu\{x : |\tilde{h}(x) - h_n(x)| \geq 2^{-n} q_0(x)/q_1(x)\} &= \mu\{x : |g(x) - (h_n \times q_1/q_0)(x)| \geq 2^{-n}\} \\ &\leq 4^n \|v - v_n\|_2^2 \leq 2^{-n}\end{aligned}$$

for every $n \in \mathbb{N}$, and $h_n \to \tilde{h}$ a.e. Similarly, $h'_n \to \tilde{h}$ a.e.

At this point, recall that K is supposed to be convex, so all the h_n, h'_n belong to K. Let $\mathcal{F}$ be any non-principal ultrafilter on $\mathbb{N}$. Because K is pointwise compact, $h = \lim_{n\to\mathcal{F}} h_n$ and $h' = \lim_{n\to\mathcal{F}} h'_n$ are both defined in K for the topology of pointwise convergence. For any x such that $\lim_{n\to\infty} h_n(x) = \tilde{h}(x)$, we surely have $h(x) = \tilde{h}(x)$; so $h =_{\text{a.e.}} \tilde{h}$. Similarly, $h' =_{\text{a.e.}} \tilde{h}$, and $h =_{\text{a.e.}} h'$.

Now at last we apply the hypothesis that distinct members of K are not equal almost everywhere, to see that $h = h'$. But if we look at what happens at the distinguished point x_0 above, we see that $f(x_0) \leq \alpha$ for every $f \in A$, so that $f(x_0) \leq \alpha$ for every $f \in \Gamma(A)$, $h_n(x_0) \leq \alpha$ for every $n \in \mathbb{N}$, and $h(x_0) \leq \alpha$; and similarly $h'(x_0) \geq \beta$. So $h \neq h'$, which is absurd. **X**

This contradiction shows that $\langle f_{n(i)} \rangle_{i\in\mathbb{N}}$ is pointwise convergent, and is an appropriate subsequence. **Q**

(b) Now 463Cd tells us that K is metrizable for $\mathfrak{T}_p$, and that $\mathfrak{T}_p$ agrees on K with the topology of convergence in measure.

463G Corollary Let $(X, \mathfrak{T}, \Sigma, \mu)$ be a σ-finite topological measure space in which μ is strictly positive. Suppose that

> whenever $h \in \mathbb{R}^X$ is such that $h\restriction C$ is continuous for every relatively countably compact $C \subseteq X$, then h is continuous.

If $K \subseteq C_b(X)$ is a norm-bounded $\mathfrak{T}_p$-compact set, then it is $\mathfrak{T}_p$-metrizable.

proof By 462J, the $\mathfrak{T}_p$-closed convex hull $\overline{\Gamma(K)}$ of K in $C_b(X)$ is $\mathfrak{T}_p$-compact. Because μ is strictly positive, $\mu\{x : f(x) \neq g(x)\} > 0$ whenever f and g are distinct continuous real-valued functions on X. So the result is immediate from 463F.

463H Lemma Let (X, Σ, μ) be a perfect probability space, and $\langle E_n\rangle_{n\in\mathbb{N}}$ a sequence in Σ. Suppose that there is an $\epsilon > 0$ such that

$$\epsilon\mu F \leq \liminf_{n\to\infty} \mu(F \cap E_n) \leq \limsup_{n\to\infty} \mu(F \cap E_n) \leq (1-\epsilon)\mu F$$

for every $F \in \Sigma$. Then $\langle E_n\rangle_{n\in\mathbb{N}}$ has a subsequence $\langle E_{n_k}\rangle_{k\in\mathbb{N}}$ such that $\mu_* A = 0$ and $\mu^* A = 1$ for any cluster point A of $\langle E_{n_k}\rangle_{k\in\mathbb{N}}$ in $\mathcal{P}X$; in particular, $\langle E_{n_k}\rangle_{k\in\mathbb{N}}$ has no measurable cluster point.

proof (a) If we replace μ by its completion, we do not change μ^* and μ_* (212Ea, 413Eg), so we may suppose that μ is already complete.

(b) Suppose that $\langle E_n\rangle_{n\in\mathbb{N}}$ is actually stochastically independent, with $\mu E_n = \frac{1}{k}$ for every n, where $k \geq 2$ is an integer. In this case $\mu^* A = 1$ for any cluster point A of $\langle E_n\rangle_{n\in\mathbb{N}}$.

P (i) There is a non-principal ultrafilter $\mathcal{F}$ on $\mathbb{N}$ such that $A = \lim_{n\to\mathcal{F}} E_n$ in $\mathcal{P}X$ (4A2Bc); that is, $\chi A(x) = \lim_{n\to\mathcal{F}} \chi E_n(x)$ for every $x \in X$; that is, $A = \{x : x \in X, \{n : x \in E_n\} \in \mathcal{F}\}$.

(ii) We have a measurable function $\phi : X \to Y = \{0,1\}^{\mathbb{N}}$ defined by setting $\phi(x)(n) = (\chi E_n)(x)$ for every $x \in X$, $n \in \mathbb{N}$. Because μ is complete and perfect and totally finite, and $\{0,1\}^{\mathbb{N}}$ is compact and metrizable, the image measure $\nu = \mu\phi^{-1}$ is a Radon measure (451N). By 451Oc, $\mu^*\phi^{-1}[B] = \nu^* B$ for every $B \subseteq Y$. Moreover, for any basic open set of the form $H = \{y : y(i) = \epsilon_i \text{ for every } i \leq n\}$, $\mu\phi^{-1}[H] = \tilde{\nu}H$, where $\tilde{\nu}$ is the product measure corresponding to the measure ν_0 on $\{0,1\}$ for which $\nu_0\{1\} = \frac{1}{k}$, $\nu_0\{0\} = \frac{k-1}{k}$. Since $\tilde{\nu}$ is also a Radon measure (416U), $\tilde{\nu} = \nu$ (415H(v)).

Set $B = \{y : y \in Y, \{n : y(n) = 1\} \in \mathcal{F}\}$, so that $\phi^{-1}[B] = A$ and B is determined by coordinates in $\{n, n+1, \dots\}$ for every $n \in \mathbb{N}$. By 451Oc, $\mu^* A = \nu^* B$; by the zero-one law (254Sa), $\nu^* B$ must be either 0 or 1. So $\mu^* A$ is either 0 or 1.

(iii) To see that $\mu^* A$ cannot be 0, we repeat the arguments of (ii) from the other side, as follows. Let λ_0 be the uniform probability measure on $\{0, 1, \dots, k-1\}$, giving measure $\frac{1}{k}$ to each point; let λ be the corresponding product measure on $Z = \{0, \dots, k-1\}^{\mathbb{N}}$. Let $\psi : Z \to Y$ be defined by setting $\psi(z)(n) = 1$ if $z(n) = 0$, 1 otherwise; then ψ is inverse-measure-preserving (254G). Since λ is a Radon measure and ψ is continuous, $\lambda\psi^{-1}$ is a Radon measure on Y and must be equal to ν. Accordingly $\nu^* B = \lambda^*\psi^{-1}[B]$, by 451Oc yet again or otherwise.

(iv) We have a measure space automorphism $\theta : Z \to Z$ defined by setting $\theta(z)(n) = z(n) +_k 1$ for every $z \in Z$, $n \in \mathbb{N}$, where $+_k$ is addition mod k. So, writing $C = \psi^{-1}[B]$, $\lambda^* C = \lambda^*\theta^i[C]$ for every $i \in \mathbb{N}$. Now, for $z \in Z$,

$$\{n : z(n) = 0\} \in \mathcal{F} \iff \{n : \psi(z)(n) = 1\} \in \mathcal{F} \iff \psi(z) \in B \iff z \in C.$$

But for any $z \in Z$, there is some $i < k$ such that $\{n : z(n) = i\} \in \mathcal{F}$, so that $\theta^{k-i}(z) \in C$. Thus $\bigcup_{i<k} \theta^i[C] = Z$ and $\sum_{i=0}^{k-1} \lambda^*\theta^i[C] \geq 1$ and $\lambda^* C > 0$. But this means that $\mu^* A = \nu^* B = \lambda^* C$ is non-zero, and $\mu^* A$ must be 1. **Q**

(c) Now return to the general case considered in (a). Note first that μ is atomless, because if $\mu F > 0$ there is some $n \in \mathbb{N}$ such that $0 < \mu(F \cap E_n) < \mu F$.

Let $k \geq 2$ be such that $\frac{1}{k} < \epsilon$. Then there are a strictly increasing sequence $\langle m(i)\rangle_{i\in\mathbb{N}}$ in $\mathbb{N}$ and a stochastically independent sequence $\langle F_i\rangle_{i\in\mathbb{N}}$ in Σ such that $F_i \subseteq E_{m(i)}$ and $\mu F_i = \frac{1}{k}$ for every $i \in \mathbb{N}$. **P** Choose $\langle m(i)\rangle_{i\in\mathbb{N}}$, F_i inductively, as follows. Let Σ_i be the (finite) algebra generated by $\{F_j : j < i\}$. Choose $m(i)$ such that $m(i) > m(j)$ for any $j < i$ and $\mu(F \cap E_{m(i)}) \geq \frac{1}{k}\mu F$ for every $F \in \Sigma_i$. List the atoms of Σ_i as $G_{i0}, \dots, G_{ip_i}$, and choose $F_{ir} \subseteq E_{m(i)} \cap G_{ir}$ such that $\mu F_{ir} = \frac{1}{k}\mu G_{ir}$, for each $r \leq p_i$; this is possible by 215D. Set $F_i = \bigcup_{r\leq p_i} F_{ir}$; then $\mu(F_i \cap F) = \frac{1}{k}\mu F$ for every $F \in \Sigma_i$. Continue. It is easy to check that $\mu(F_{i_1} \cap \dots \cap F_{i_r}) = 1/k^r$ whenever $i_1 < \dots < i_r$, so that $\langle F_i\rangle_{i\in\mathbb{N}}$ is stochastically independent. **Q**

If A is a cluster point of $\langle E_{m(i)}\rangle_{i\in\mathbb{N}}$, then there is a non-principal ultrafilter $\mathcal{F}$ on $\mathbb{N}$ such that $A = \lim_{i\to\mathcal{F}} E_{m(i)}$ in $\mathcal{P}X$. In this case, $A \supseteq A'$, where $A' = \lim_{i\to\mathcal{F}} F_i$. But (b) tells us that $\mu^* A'$ must be 1, so $\mu^* A = 1$.

(d) Thus we have a subsequence $\langle E_{m(i)}\rangle_{i\in\mathbb{N}}$ of $\langle E_n\rangle_{n\in\mathbb{N}}$ such that any cluster point of $\langle E_{m(i)}\rangle_{i\in\mathbb{N}}$ has outer measure 1. But the same argument applies to $\langle X \setminus E_{m(i)}\rangle_{i\in\mathbb{N}}$ to show that there is a strictly increasing sequence $\langle i_k\rangle_{k\in\mathbb{N}}$ such that every cluster point of $\langle X \setminus E_{m(i_k)}\rangle_{k\in\mathbb{N}}$ has outer measure 1. Since complementation

is a homeomorphism of $\mathcal{P}X$, $\mu^*(X \setminus A) = 1$, that is, $\mu_* A = 0$, for every cluster point A of $\langle E_{m(i_k)}\rangle_{k\in\mathbb{N}}$. So if we set $n(k) = m(i_k)$, any cluster point of $\langle E_{n_k}\rangle_{k\in\mathbb{N}}$ will have inner measure 0 and outer measure 1, as claimed.

463I Lemma Let (X, Σ, μ) be a perfect probability space, and $\langle E_n\rangle_{n\in\mathbb{N}}$ a sequence in Σ. Then
either $\langle \chi E_n\rangle_{n\in\mathbb{N}}$ has a subsequence which is convergent almost everywhere
or $\langle E_n\rangle_{n\in\mathbb{N}}$ has a subsequence with no measurable cluster point in $\mathcal{P}X$.

proof Consider the sequence $\langle \chi E_n^\bullet\rangle_{n\in\mathbb{N}}$ in the Hilbert space $L^2 = L^2(\mu)$. This is a norm-bounded sequence, so has a weakly convergent subsequence $\langle \chi E_{n_i}^\bullet\rangle_{i\in\mathbb{N}}$ with limit v say (4A4Kb). Express v as $g^\bullet$ where $g : X \to \mathbb{R}$ is Σ-measurable.

case 1 Suppose that $g(x) \in \{0, 1\}$ for almost every $x \in X$; set $F = \{x : g(x) = 1\}$. Then

$$\lim_{i\to\infty} \int_F \chi E_{n_i} = \int_F g = \mu F, \quad \lim_{i\to\infty} \int_{X\setminus F} \chi E_{n_i} = \int_{X\setminus F} g = 0.$$

So, replacing $\langle \chi E_{n_i}\rangle_{i\in\mathbb{N}}$ with a sub-subsequence if necessary, we may suppose that

$$|\mu F - \int_F \chi E_{n_i}| \le 2^{-i}, \quad |\int_{X\setminus F} \chi E_{n_i}| \le 2^{-i}$$

for every i. But as $0 \le \chi E_{n_i} \le 1$ everywhere, we have

$$\int |\chi F - \chi E_{n_i}| \le 2^{-i+1}$$

for every i, so that $\chi E_{n_i} \to \chi F$ a.e., and we have a subsequence of $\langle \chi E_n\rangle_{n\in\mathbb{N}}$ which is convergent almost everywhere.

case 2 Suppose that $\{x : g(x) \notin \{0, 1\}\}$ has positive measure. Note that because $\int_F g = \lim_{i\to\infty} \mu(F \cap E_{n_i})$ lies between 0 and μF for every $F \in \Sigma$, $0 \le g \le 1$ a.e., and $\mu\{x : 0 < g(x) < 1\} > 0$. There is therefore an $\epsilon > 0$ such that $\mu G > 0$, where $G = \{x : \epsilon \le g(x) \le 1 - \epsilon\}$.

Write μ_G for the subspace measure on G, and Σ_G for its domain; set $\nu = (\mu G)^{-1}\mu_G$, so that ν is a probability measure. We know that μ_G is perfect (451Dc), so ν also is (see the definition in 451Ad). Now if $F \in \Sigma_G$,

$$\lim_{i\to\infty} \nu(F \cap E_{n_i}) = (\mu G)^{-1} \int_F g$$

lies between $\epsilon\mu F/\mu G = \epsilon\nu F$ and $(1 - \epsilon)\nu F$.

By 463H, there is a strictly increasing sequence $\langle i(k)\rangle_{k\in\mathbb{N}}$ such that $B \notin \Sigma_G$ whenever B is a cluster point of $\langle G \cap E_{n_{i(k)}}\rangle_{k\in\mathbb{N}}$ in $\mathcal{P}G$. If A is any cluster point of $\langle E_{n_{i(k)}}\rangle_{k\in\mathbb{N}}$ in $\mathbb{R}^X$, then $A \cap G$ is a cluster point of $\langle G \cap E_{n_{i(k)}}\rangle_{k\in\mathbb{N}}$ in $\mathcal{P}G$, so cannot belong to Σ_G. Thus $A \notin \Sigma$.

So in this case we have a subsequence $\langle E_{n_{i(k)}}\rangle_{k\in\mathbb{N}}$ of $\langle E_n\rangle_{n\in\mathbb{N}}$ which has no measurable cluster point.

463J Fremlin's Alternative (FREMLIN 75A) Let (X, Σ, μ) be a perfect σ-finite measure space, and $\langle f_n\rangle_{n\in\mathbb{N}}$ a sequence of real-valued measurable functions on X. Then
either $\langle f_n\rangle_{n\in\mathbb{N}}$ has a subsequence which is convergent almost everywhere
or $\langle f_n\rangle_{n\in\mathbb{N}}$ has a subsequence with no measurable cluster point in $\mathbb{R}^X$.

proof (a) If $\mu X = 0$ then of course $\langle f_n\rangle_{n\in\mathbb{N}}$ itself is convergent a.e., so we may suppose that $\mu X > 0$. If there is any $x \in X$ such that $\sup_{n\in\mathbb{N}} |f_n(x)| = \infty$, then $\langle f_n\rangle_{n\in\mathbb{N}}$ has a subsequence with no cluster point in $\mathbb{R}^X$, measurable or otherwise; so we may suppose that $\langle f_n\rangle_{n\in\mathbb{N}}$ is bounded at each point of X.

(b) Let λ be the c.l.d. product of μ with Lebesgue measure on $\mathbb{R}$, and Λ its domain. Then λ is perfect (451Ic) and also σ-finite (251K). There is therefore a probability measure ν on Y with the same domain and the same negligible sets as λ (215B(vii)), so that ν also is perfect. For any function $h \in \mathbb{R}^X$, write

$$\Omega(h) = \{(x, \alpha) : x \in X, \alpha \le h(x)\} \subseteq X \times \mathbb{R}$$

(compare 252N).

(c) By 463I, applied to the measure space $(X \times \mathbb{R}, \Lambda, \nu)$ and the sequence $\langle \chi\Omega(f_n)\rangle_{n\in\mathbb{N}}$, we have a strictly increasing sequence $\langle n(i)\rangle_{i\in\mathbb{N}}$ such that either $\langle \chi\Omega(f_{n(i)})\rangle_{i\in\mathbb{N}}$ is convergent ν-a.e. or $\langle \Omega(f_{n(i)})\rangle_{i\in\mathbb{N}}$ has no cluster point in Λ.

case 1 Suppose that $\langle \chi\Omega(f_{n(i)})\rangle_{i\in\mathbb{N}}$ is convergent ν-a.e. Set

$$W = \{(x,\alpha) : \lim_{i\to\infty} \chi\Omega(f_{n(i)})(x,\alpha) \text{ is defined}\}.$$

Then W is λ-conegligible, so $W^{-1}[\{\alpha\}] = \{x : (x,\alpha)\in W\}$ is μ-conegligible for almost every α (252D). Set $D = \{\alpha : W^{-1}[\{\alpha\}] \text{ is } \mu\text{-conegligible}\}$, and let $Q\subseteq D$ be a countable dense set; then $G = \bigcap_{\alpha\in Q} W^{-1}[\{\alpha\}]$ is μ-conegligible. But if $x\in G$, then for any $\alpha\in Q$ the set $\{i : f_{n(i)}(x)\geq\alpha\} = \{i : \chi\Omega(f_{n(i)})(x,\alpha) = 1\}$ is either finite or has finite complement in $\mathbb{N}$, so $\langle f_{n(i)}(x)\rangle_{i\in\mathbb{N}}$ must be convergent in $[-\infty,\infty]$. Since $\langle f_n(x)\rangle_{n\in\mathbb{N}}$ is supposed to be bounded, $\langle f_{n(i)}(x)\rangle_{i\in\mathbb{N}}$ is convergent in $\mathbb{R}$. Thus in this case we have an almost-everywhere-convergent subsequence of $\langle f_n\rangle_{n\in\mathbb{N}}$.

case 2 Suppose that $\langle\Omega(f_{n(i)})\rangle_{i\in\mathbb{N}}$ has no cluster point in Λ. Let h be any cluster point of $\langle f_{n(i)}\rangle_{i\in\mathbb{N}}$ in $\mathbb{R}^X$. Then there is a non-principal ultrafilter $\mathcal{F}$ on $\mathbb{N}$ such that $h = \lim_{i\to\mathcal{F}} f_{n(i)}$ in $\mathbb{R}^X$. Set $A = \lim_{i\to\mathcal{F}}\Omega(f_{n(i)})$, so that $A\notin\Lambda$. If $x\in X$ and $\alpha\in\mathbb{R}$, then

$$\alpha < h(x) \Longrightarrow \{i : \alpha < f_{n(i)}(x)\}\in\mathcal{F} \Longrightarrow (x,\alpha)\in A,$$

$$h(x) < \alpha \Longrightarrow \{i : \alpha < f_{n(i)}(x)\}\notin\mathcal{F} \Longrightarrow (x,\alpha)\notin A.$$

Thus $\Omega'(h)\subseteq A\subseteq\Omega(h)$, where $\Omega'(h) = \{(x,\alpha) : \alpha < h(x)\}$.

? If h is Σ-measurable, then

$$\Omega'(h) = \textstyle\bigcup_{q\in\mathbb{Q}}\{x : h(x) > q\}\times\,]-\infty,q],$$

$$\Omega(h) = (X\times\mathbb{R})\setminus\textstyle\bigcup_{q\in\mathbb{Q}}\{x : h(x) < q\}\times[q,\infty[$$

belong to Λ, and $\lambda(\Omega(h)\setminus\Omega'(h)) = 0$ (because every vertical section of $\Omega(h)\setminus\Omega'(h)$ is negligible). But as $\Omega'(h)\subseteq A\subseteq\Omega(h)$, $A\in\Lambda$ (remember that product measures in this book are complete), which is impossible. **X**

Thus h is not Σ-measurable. As h is arbitrary, $\langle f_{n(i)}\rangle_{i\in\mathbb{N}}$ has no measurable cluster point in $\mathbb{R}^X$.

So at least one of the envisaged alternatives must be true.

463K Corollary Let (X,Σ,μ) be a perfect σ-finite measure space. Write $\mathcal{L}^0\subseteq\mathbb{R}^X$ for the space of real-valued Σ-measurable functions on X.

(a) If $K\subseteq\mathcal{L}^0$ is relatively countably compact for the topology $\mathfrak{T}_p$ of pointwise convergence on $\mathcal{L}^0$, then every sequence in K has a subsequence which is convergent almost everywhere. Consequently K is relatively compact in $\mathcal{L}^0$ for the topology $\mathfrak{T}_m$ of convergence in measure.

(b) If $K\subseteq\mathcal{L}^0$ is countably compact for $\mathfrak{T}_p$, then it is compact for $\mathfrak{T}_m$.

(c) Suppose that $K\subseteq\mathcal{L}^0$ is countably compact for $\mathfrak{T}_p$ and that $\mu\{x : f(x)\neq g(x)\} > 0$ for any distinct $f, g\in K$. Then the topologies $\mathfrak{T}_m$, $\mathfrak{T}_p$ agree on K, so both are compact and metrizable.

proof (a) Since every sequence in K must have a $\mathfrak{T}_p$-cluster point in $\mathcal{L}^0$, 463J tells us that every sequence in K has a subsequence which is convergent almost everywhere, therefore $\mathfrak{T}_m$-convergent. Now K is relatively sequentially compact in the pseudometrizable space $(\mathcal{L}^0,\mathfrak{T}_m)$, therefore relatively compact (4A2Le).

(b) As in (a), every sequence $\langle f_n\rangle_{n\in\mathbb{N}}$ in K has a subsequence $\langle g_n\rangle_{n\in\mathbb{N}}$ which is convergent almost everywhere. But $\langle g_n\rangle_{n\in\mathbb{N}}$ has a $\mathfrak{T}_p$-cluster point g in K, and now $g(x) = \lim_{n\to\infty} g_n(x)$ for every x for which the limit is defined; accordingly $g_n\to g$ a.e., and g is a $\mathfrak{T}_m$-limit of $\langle g_n\rangle_{n\in\mathbb{N}}$ in K. Thus every sequence in K has a $\mathfrak{T}_m$-cluster point in K, and (because $\mathfrak{T}_m$ is pseudometrizable) K is $\mathfrak{T}_m$-compact.

(c) The point is that K is sequentially compact under $\mathfrak{T}_p$. **P** Note that as K is countably compact, $\sup_{f\in K}|f(x)|$ is finite for every $x\in K$. (I am passing over the trivial case $K = \emptyset$.) If $\langle f_n\rangle_{n\in\mathbb{N}}$ is a sequence in K, then, by (b), it has a subsequence $\langle g_n\rangle_{n\in\mathbb{N}}$ which is convergent for the pseudometrizable topology $\mathfrak{T}_m$. Now $\langle g_n\rangle_{n\in\mathbb{N}}$ has a further subsequence $\langle h_n\rangle_{n\in\mathbb{N}}$ which is convergent a.e., by 245K. **?** If $\langle h_n\rangle_{n\in\mathbb{N}}$ is not $\mathfrak{T}_p$-convergent, then there are a point $x_0\in X$ and two further subsequences $\langle h'_n\rangle_{n\in\mathbb{N}}$, $\langle h''_n\rangle_{n\in\mathbb{N}}$ of $\langle h_n\rangle_{n\in\mathbb{N}}$ such that $\lim_{n\to\infty} h'_n(x_0)$, $\lim_{n\to\infty} h''_n(x_0)$ exist and are different. Now $\langle h'_n\rangle_{n\in\mathbb{N}}$, $\langle h''_n\rangle_{n\in\mathbb{N}}$ must have cluster points h', $h''\in K$ with $h'(x_0)\neq h''(x_0)$.

However,

$$h'(x) = \lim_{n\to\infty} h_n(x) = h''(x)$$

whenever the limit is defined, which is almost everywhere; so $h' =_{\text{a.e.}} h''$. And this contradicts the hypothesis that if two elements of K are equal a.e., they are identical. **X** Thus $\langle h_n\rangle_{n\in\mathbb{N}}$ is a $\mathfrak{T}_p$-convergent subsequence of $\langle f_n\rangle_{n\in\mathbb{N}}$. As $\langle f_n\rangle_{n\in\mathbb{N}}$ is arbitrary, K is $\mathfrak{T}_p$-sequentially compact. **Q**

Now 463Cd gives the result.

463L Proposition Let $X_0, \dots, X_n$ be compact Hausdorff spaces, each carrying a strictly positive Radon measure. Let X be their product and $\mathcal{B}\mathfrak{a}(X)$ the Baire σ-algebra of X. Then any separately continuous function $f : X \to \mathbb{R}$ is $\mathcal{B}\mathfrak{a}(X)$-measurable.

proof For $i \le n$ let μ_i be a strictly positive Radon measure on X_i; let μ be the product Radon measure on X.

(a) The proof relies on the fact that

($*$) if $g, g' : X \to \mathbb{R}$ are distinct separately continuous functions, then $\mu\{x : g(x) \ne g'(x)\} > 0$;

I seek to prove this, together with the stated result, by induction on n. The induction starts easily with $n = 0$, so that X can be identified with X_0, a separately continuous function on X is just a continuous function on X_0, and ($*$) is true because $\mu = \mu_0$ is strictly positive.

(b) For the inductive step to $n+1$, given a separately continuous function $f : X_0 \times \dots \times X_{n+1} \to \mathbb{R}$, set $f_t(y) = f(y,t)$ for every $y \in Y = X_0 \times \dots \times X_n$ and $t \in X_{n+1}$. Then every f_t is separately continuous, therefore $\mathcal{B}\mathfrak{a}(Y)$-measurable, by the inductive hypothesis. Moreover, again because f is separately continuous, the function $t \mapsto f_t(y)$ is continuous for every y, that is, $t \mapsto f_t : X_{n+1} \to \mathbb{R}^Y$ is continuous; and finally, by the inductive hypothesis ($*$), $\nu\{y : f_t(y) \ne f_{t'}(y)\} > 0$ whenever $t, t' \in X_{n+1}$ and $f_t \ne f_{t'}$, where ν is the product Radon measure on Y.

Since ν, being a Radon measure, is perfect (416W), we can apply 463Kc to see that $K = \{f_t : t \in X_{n+1}\}$ is metrizable for the topology of pointwise convergence. Let ρ be a metric on K inducing its topology, and $\langle g_i\rangle_{i\in\mathbb{N}}$ a sequence running over a dense subset of K. (I am passing over the trivial case $K = \emptyset = X_{n+1}$.) For $m, i \in \mathbb{N}$ set

$$E_{mi} = \{t : \rho(f_t, g_i) \le 2^{-m},\ \rho(f_t, g_j) > 2^{-m} \text{ for } j < i\},$$

so that every E_{mi} belongs to $\mathcal{B}\mathfrak{a}(X_{n+1})$. Set $f^{(m)}(y,t) = g_i(y)$ for $t \in E_{mi}$. Then $f^{(m)} : X \to \mathbb{R}$ is $\mathcal{B}\mathfrak{a}(X)$-measurable because every g_i is $\mathcal{B}\mathfrak{a}(Y)$-measurable, every E_{mi} belongs to $\mathcal{B}\mathfrak{a}(X_{m+1})$, and $\mathcal{B}\mathfrak{a}(X) = \mathcal{B}\mathfrak{a}(Y)\widehat{\otimes}\mathcal{B}\mathfrak{a}(X_{n+1})$ (4A3Od). Also $\langle f^{(m)}\rangle_{m\in\mathbb{N}} \to f$ at every point, because $\rho(f_t^{(m)}, f_t) \le 2^{-m}$ for every $m \in \mathbb{N}$ and $t \in X_{n+1}$. So f is $\mathcal{B}\mathfrak{a}(X)$-measurable.

(c) We still have to check that ($*$) is true at the new level. But if $h, h' : X \to \mathbb{R}$ are distinct separately continuous functions, then there are $t_0 \in X_{n+1}$, $y_0 \in Y$ such that $h(y_0, t_0) \ne h'(y_0, t_0)$. Let G be an open set containing t_0 such that $h(y_0, t) \ne h'(y_0, t)$ whenever $t \in G$. Then $\nu\{y : h(y,t) \ne h'(y,t)\} > 0$ for every $t \in G$, by the inductive hypothesis, so

$$\mu\{(y,t) : h(y,t) \ne h'(y,t)\} = \int \nu\{y : h(y,t) \ne h'(y,t)\}\mu_{n+1}(dt) > 0$$

because μ_{n+1} is strictly positive. Thus the induction continues.

463M Corollary Let $X_0, \dots, X_n$ be Hausdorff spaces with product X, and μ any Radon measure on X; let Σ be the domain of μ. Then every separately continuous function $f : X \to \mathbb{R}$ is Σ-measurable.

proof (a) Suppose first that there is a conegligible compact set $C \subseteq X$. For each $i \le n$, let $\pi_i : X \to X_i$ be the coordinate projection, and $\mu_i = \mu\pi_i^{-1}$ the image Radon measure; let Z_i be the support of μ_i and $Z = \prod_{i\le n} Z_i$. Note that every Z_i is a closed subset of $\pi_i[C]$, so that Z_i is compact and $C \subseteq Z$. By 463L, $f\restriction Z$ is $\mathcal{B}\mathfrak{a}(Z)$-measurable; because Z is conegligible, f is Σ-measurable.

(b) In general, if $C \subseteq X$ is compact, then we can apply (a) to the measure $E \mapsto \mu(E \cap C)$ to see that $f\restriction C$ is measurable. As μ is complete and locally determined and tight (that is, inner regular with respect to the compact sets), f is measurable (see 412Ja).

***463N** There are important open questions concerning the possibility of extending the results of 463K to non-perfect measure spaces (see 463Za-463Zb). I give here one curious fact which is relevant to a question which arises naturally in the next section.

Proposition Let (X, Σ, μ) be a σ-finite measure space, and $\mathcal{L}^0$ the space of Σ-measurable real-valued functions on X. Suppose that $K \subseteq \mathcal{L}^0$ is an infinite set, compact for the topology $\mathfrak{T}_p$ of pointwise convergence, and that $\mu\{x : f(x) \neq g(x)\} > 0$ for any distinct f, $g \in K$. Then there is a sequence of distinct elements of K which is $\mathfrak{T}_p$-convergent.

proof (a) To begin with (down to the end of (c) below) I will suppose that $\mu X = 1$ and that $0 \leq f \leq \chi X$ for every $f \in K$.

For any set $A \subseteq K$, define $\Delta(A)$ as follows. If $A = \emptyset$, then $\Delta(A) = 0$. Otherwise, set $\Delta(A) = \underline{\int}(\sup A - \inf A)d\mu$, where $\sup A$ and $\inf A$ are taken in $\mathbb{R}^X$, and $\underline{\int} d\mu$ is the lower integral (133I). (There is no suggestion at this point that $\sup A$ or $\inf A$ should be measurable.) Clearly $\Delta(A) \leq \Delta(B)$ whenever $A \subseteq B \subseteq K$. If A has more than one member, then $\Delta(A) > 0$, because two elements of K which are equal a.e. are identical; this is where I use the hypothesis that K is separated by the topology of convergence in measure.

(b) ? Now suppose, if possible, that there is no non-trivial convergent sequence in K. (Here, and henceforth, all topological terms will refer to the topology $\mathfrak{T}_p$.) Then there is an infinite closed set $K_1 \subseteq K$ such that $\Delta(L) = \Delta(K_1)$ for every infinite closed set $L \subseteq K_1$. **P** Write $\mathcal{L}$ for the family of infinite closed subsets of K. For $L \in \mathcal{L}$, set $\underline{\Delta}(L) = \inf\{\Delta(L') : L' \in \mathcal{L}, L' \subseteq L\}$. Choose $\langle L_n\rangle_{n\in\mathbb{N}}$ in $\mathcal{L}$ inductively, as follows. $L_0 = K$. Given L_n, let $L_{n+1} \in \mathcal{L}$ be such that $L_{n+1} \subseteq L_n$ and $\Delta(L_{n+1}) \leq \underline{\Delta}(L_n) + 2^{-n}$; continue. At the end of the induction, set $K_1 = \bigcap_{n\in\mathbb{N}} L_n$. Because there are supposed to be no convergent sequences in K, K_1 must be infinite (4A2G(h-i)). Now

$$\Delta(K_1) \leq \inf_{n\in\mathbb{N}} \Delta(L_n) \leq \sup_{n\in\mathbb{N}} \underline{\Delta}(L_n) \leq \underline{\Delta}(K_1) \leq \Delta(K_1),$$

so $\Delta(L) = \Delta(K_1)$ whenever $L \subseteq K_1$ and $L \in \mathcal{L}$, as required. **Q**

(c) Now there is no non-trivial convergent sequence in K_1, so K_1 cannot be scattered (4A2G(h-ii)), and it must have an infinite closed subset K_2 without isolated points which has a countable π-base $\mathcal{U}$ say (4A2G(i-iii)). We may suppose that $\emptyset \notin \mathcal{U}$. Set $g_0 = \inf K_2$, $g_1 = \sup K_2$ in $\mathbb{R}^X$. Then g_0 and g_1 are measurable. **P** For each non-empty $U \in \mathcal{U}$, choose $h_U \in U$. Then $g_0' = \inf_{U\in\mathcal{U}} h_U$ is measurable, and $g_0 \leq g_0'$. But, for any $t \in X$, $\{f : f \in K_2, f(t) < g_0'(t)\}$ is a relatively open set in K_2, not containing any h_U and therefore not including any member of $\mathcal{U}$, and must accordingly be empty. This means that $g_0' \leq f$ for every $f \in K_2$ and $g_0 = g_0'$ is measurable. Similarly, $g_1 = \sup_{U\in\mathcal{U}} h_U$ is measurable. **Q**

Since

$$\int g_1 - g_0 = \underline{\int} g_1 - g_0 = \Delta(K_2) > 0,$$

there is a rational number α such that $E = \{t : g_0(t) < \alpha < g_1(t)\}$ is non-negligible. For $t \in E$, the set $\{f : f \in K_2, f(t) < \alpha\}$ is a non-empty relatively open set in K_2, so includes some member U_t of $\mathcal{U}$. Because $\mathcal{U}$ is countable, there is a $U \in \mathcal{U}$ such that $D = \{t : t \in E, U_t = U\}$ is non-negligible. But now observe that $f(t) < \alpha$ whenever $f \in U$ and $t \in D$, so $f(t) \leq \alpha$ whenever $f \in \overline{U}$ and $t \in D$. Now there is a measurable function h such that $h \leq \sup\overline{U} - \inf\overline{U}$ and $\int h = \Delta(\overline{U})$ (133J(a-ii)). In this case $h \leq g_1 - g_0$ and also $\{t : h(t) < g_1(t) - g_0(t)\} \supseteq D$ is non-negligible, so that

$$\Delta(\overline{U}) = \int h < \int g_1 - g_0 = \Delta(K_2).$$

On the other hand, U is infinite, because K_2 has no isolated points, so $\overline{U}$ is an infinite closed subset of K_2 with $\Delta(\overline{U}) < \Delta(K_2)$; which contradicts the choice of K_2. **X**

(d) This shows that, at least in the case in which $\mu X = 1$ and $K \subseteq [0,1]^X$, K has a non-trivial convergent sequence. For the general case, observe that μX is certainly non-zero (since K contains functions which are not equal a.e.), so there is a probability measure ν with the same measurable sets and the same negligible sets (215B(vii)). Moreover, if we set $q(f)(t) = \frac{1}{2}(1 + \frac{f(t)}{1+|f(t)|})$ for $f \in \mathbb{R}^X$ and $t \in X$, then $K' = \{q(f) : f \in K\}$ is homeomorphic to K, and it is still true that $\nu\{t : f(t) \neq g(t)\} > 0$ for all distinct f, $g \in K'$, while K' is bounded by the constant functions $\mathbf{0}$ and χX. So, applying (a)-(c) to ν and K', we see that K' has a non-trivial convergent sequence and therefore K also does.

***463O Corollary** (Talagrand 80) Under the hypotheses of 463N, K cannot be homeomorphic to $\beta\mathbb{N}$, the Stone-Čech compactification of $\mathbb{N}$.

proof For there are no non-trivial convergent sequences in $\beta\mathbb{N}$ (4A2I(b-iv)).

463X Basic exercises >(a) Let (X, Σ, μ) be a measure space, $\mathcal{L}^0$ the space of Σ-measurable real-valued functions on X, $\mathfrak{T}_p$ the topology of pointwise convergence on $\mathcal{L}^0$ and $\mathfrak{T}_m$ the topology of convergence in measure on $\mathcal{L}^0$. (i) Show that $\mathfrak{T}_m \subseteq \mathfrak{T}_p$ iff for every measurable set E of finite measure there is a countable set $D \subseteq E$ such that $\mu^* D = \mu E$. (ii) Show that $\mathfrak{T}_p \subseteq \mathfrak{T}_m$ iff $0 < \mu^*\{x\} < \infty$ for every $x \in X$.

(b) Let (X, Σ, μ) be a σ-finite measure space, and $K \subseteq \mathcal{L}^0(\Sigma)$ a $\mathfrak{T}_p$-countably compact set. Show that the following are equiveridical: (i) every sequence in K has a subsequence which converges almost everywhere; (ii) K is $\mathfrak{T}_m$-compact; (iii) K is totally bounded for the uniformity associated with the linear space topology $\mathfrak{T}_m$. Show that if moreover the topology on K induced by $\mathfrak{T}_m$ is Hausdorff, then K is $\mathfrak{T}_p$-metrizable.

(c) Let (X, Σ, μ) be a complete locally determined measure space, and $K \subseteq \mathcal{L}^0(\Sigma)$ a set such that whenever $E \in \Sigma$ is a non-negligible measurable set and $\epsilon > 0$, there is a non-negligible measurable set $F \subseteq E$ such that $|f(x) - f(y)| \leq \epsilon$ whenever $f \in K$ and $x, y \in F$. Show that $\mathfrak{T}_p$ and $\mathfrak{T}_m$ agree on K, and that if $\sup_{f \in K} |f(x)|$ is finite for every $x \in X$ then K is relatively compact in $\mathcal{L}^0$ for both topologies.

(d) (i) Show that there is a set of Borel measurable functions on $[0, 1]$ which countably tight, compact and non-metrizable for the topology of pointwise convergence. (ii) Show that there is a strictly localizable measure space (X, Σ, μ) with a set K of measurable functions which is countably tight, compact, Hausdorff and non-metrizable for both the topology of pointwise convergence and the topology of convergence in measure. (*Hint*: the one-point compactification of any discrete space is countably tight.)

(e) Let X be a topological space and $K \subseteq C(X)$ a convex $\mathfrak{T}_p$-compact set. Show that if there is a strictly positive σ-finite topological measure on X, then K is $\mathfrak{T}_p$-metrizable.

(f) Use Komlós' theorem (276H) to shorten the proof of 463F.

(g) Let (X, Σ, μ) be any complete σ-finite measure space. Show that if $K \subseteq \mathcal{L}^0(\Sigma)$ is $\mathfrak{T}_m$-relatively compact, and $\sup_{f \in K} |f(x)|$ is finite for every $x \in X$, then K is $\mathfrak{T}_p$-relatively countably compact in $\mathcal{L}^0(\Sigma)$.

(h) Let K be the set of non-decreasing functions from $[0, 1]$ to $\{0, 1\}$. Show that K, with its topology of pointwise convergence, is homeomorphic to the split interval (419L). Show that the identity map from $(K, \mathfrak{T}_p)$ to $(K, \mathfrak{T}_m)$ (for any Radon measure μ on $[0, 1]$) is continuous.

>(i) Let K be the set of non-decreasing functions from ω_1 to $\{0, 1\}$. Show that if μ is the countable-cocountable measure on ω_1 then K is a $\mathfrak{T}_p$-compact set of measurable functions and is also $\mathfrak{T}_m$-compact, but the identity map from $(K, \mathfrak{T}_p)$ to $(K, \mathfrak{T}_m)$ is not continuous.

>(j) Let K be the set of functions $f : [0, 1] \to \mathbb{R}$ such that $\max(\|f\|_\infty, \operatorname{Var}_{[0,1]} f) \leq 1$, where $\operatorname{Var}_{[0,1]} f$ is the variation of f (224A). Show that K is $\mathfrak{T}_p$-compact and that (for any Radon measure on $[0, 1]$) the identity map from $(K, \mathfrak{T}_p)$ to $(K, \mathfrak{T}_m)$ is continuous.

>(k) Let A be the set of functions $f : [0, 1] \to [0, 1]$ such that $\overline{\int} |f| d\mu \cdot \operatorname{Var}_{[0,1]} f \leq 1$, where μ is Lebesgue measure. Show that every member of A is measurable and that every sequence in A has a subsequence which converges almost everywhere to a member of A, but that $\int : A \to [0, 1]$ is not $\mathfrak{T}_p$-continuous, while A is $\mathfrak{T}_p$-dense in $[0, 1]^{[0,1]}$.

(l) Let X be a Hausdorff space and $K \subseteq C(X)$ a $\mathfrak{T}_p$-compact set. Show that if there is a strictly positive σ-finite Radon measure on X then K is $\mathfrak{T}_p$-metrizable.

>(m) Let (X, Σ, μ) be any perfect measure space and $K \subseteq \mathcal{L}^0(\Sigma)$ a $\mathfrak{T}_p$-compact set. Show that the identity map on K is $(\mathfrak{T}_p, \mathfrak{T}_m)$-continuous, so that K is $\mathfrak{T}_m$-compact.

(n) Let (X, Σ, μ) be a localizable measure space and $K \subseteq \mathcal{L}^0(\Sigma)$ a non-empty $\mathfrak{T}_p$-compact set. Show that $\sup\{f^\bullet : f \in K\}$ is defined in $L^0(\mu)$.

463Y Further exercises (a) Let (X, Σ, μ) be a probability space and V a Banach space. A function $\phi : X \to V$ is **scalarly measurable** (often called **weakly measurable**) if $h\phi : X \to \mathbb{R}$ is Σ-measurable for every $h \in V^*$. ϕ is **Pettis integrable**, with **indefinite Pettis integral** $\theta : \Sigma \to V$, if $\int_E h\phi \, d\mu$ is defined and equal to $h(\theta E)$ for every $E \in \Sigma$ and every $h \in V^*$. (i) Show that if ϕ is scalarly measurable, then $K = \{h\phi : h \in V^*, \|h\| \leq 1\}$ is a $\mathfrak{T}_p$-compact subset of $\mathcal{L}^0(\Sigma)$. (ii) Show that if ϕ is scalarly measurable, then it is Pettis integrable iff every function in K is integrable and $f \mapsto \int_E f : K \to \mathbb{R}$ is $\mathfrak{T}_p$-continuous for every $E \in \Sigma$. (*Hint*: 4A4Cg.) (iii) In particular, if ϕ is bounded and scalarly measurable and the identity map from $(K, \mathfrak{T}_p)$ to $(K, \mathfrak{T}_m)$ is continuous, then ϕ is Pettis integrable. (See Talagrand 84, chap. 4.)

(b) Show that any Bochner integrable function (253Yf) is Pettis integrable.

(c) Let μ be Lebesgue measure on $[0,1]$, and define $\phi : [0,1] \to L^\infty(\mu)$ by setting $\phi(t) = \chi[0,t]^\bullet$ for every $t \in [0,1]$. (i) Show that if $h \in L^\infty(\mu)^*$ and $\|h\| \leq 1$, then $h\phi$ has variation at most 1. (ii) Show that $K = \{h\phi : h \in L^\infty(\mu)^*, \|h\| \leq 1\}$ is a $\mathfrak{T}_p$-compact set of Lebesgue measurable functions, and that the identity map from $(K, \mathfrak{T}_p)$ to $(K, \mathfrak{T}_m)$ is continuous, so that ϕ is Pettis integrable. (iii) Show that ϕ is not Bochner integrable.

(d) Let (X, Σ, μ) be a σ-finite measure space and suppose that μ is inner regular with respect to some family $\mathcal{E} \subseteq \Sigma$ of cardinal at most ω_1. (Subject to the continuum hypothesis, this is true for any subset of $\mathbb{R}$, for instance.) Show that if $K \subseteq \mathcal{L}^0(\Sigma)$ is $\mathfrak{T}_p$-compact then it is $\mathfrak{T}_m$-compact. (See Talagrand 84, 9-3-3.)

(e) Assume that the continuum hypothesis is true; let $\preccurlyeq$ be a well-ordering of $[0,1]$ with order type ω_1 (4A1Ad). Let (Z, ν) be the Stone space of the measure algebra of Lebesgue measure on $[0,1]$, and $q : Z \to [0,1]$ the canonical inverse-measure-preserving map (416V). Let $g : [0,1] \to [0, \infty[$ be any function. Show that there is a function $f : [0,1] \times Z \to [0, \infty[$ such that (α) f is continuous in the second variable (β) $f(t,z) = 0$ whenever $q(z) \preccurlyeq t$ (γ) $\int f(t,z)\nu(dz) = g(t)$ for every $t \in [0,1]$. Show that f is universally measurable in the first variable, but need not be measurable for the product Radon measure on $[0,1] \times Z$. Setting $f_z(t) = f(t,z)$, show that $K = \{f_z : z \in Z\}$ is a $\mathfrak{T}_p$-compact set of Lebesgue measurable functions and that g belongs to the $\mathfrak{T}_p$-closed convex hull of K in $\mathbb{R}^{[0,1]}$.

463Z Problems (a) A.Bellow's problem Let (X, Σ, μ) be a probability space, and $K \subseteq \mathcal{L}^0(\Sigma)$ a $\mathfrak{T}_p$-compact set such that $\{x : f(x) \neq g(x)\}$ is non-negligible for any distinct functions $f, g \in K$, as in 463F and 463Kc. Does it follow that K is metrizable for $\mathfrak{T}_p$?

A positive answer would displace several of the arguments of this section, and have other consequences (see 462Z, for instance). It is known that under any of a variety of special axioms (starting with the continuum hypothesis) there is indeed a positive answer; see Talagrand 84, chap. 12.

(b) Let $X \subseteq [0,1]$ be a set of outer Lebesgue measure 1, and μ the subspace measure on X, with Σ its domain. Let K be a $\mathfrak{T}_p$-compact subset of $\mathcal{L}^0(\Sigma)$. Must K be $\mathfrak{T}_m$-compact?

(c) Let $X_0, \ldots, X_n$ be compact Hausdorff spaces and $f : X_0 \times \ldots \times X_n \to \mathbb{R}$ a separately continuous function. Must f be universally measurable?

463 Notes and comments The relationship between the topologies $\mathfrak{T}_p$ and $\mathfrak{T}_m$ is complex, and I do not think that the results here are complete; in particular, we have a remarkable outstanding problem in 463Za. Much of the work presented here has been stimulated by problems concerning the integration of vector-valued functions. I am keeping this theory firmly in the 'further exercises' (463Ya-463Yc), but it is certainly the most important source of examples of pointwise compact sets of measurable functions. In particular, since the set $\{h\phi : h \in V^*, \|h\| \leq 1\}$ is necessarily convex whenever V is a Banach space and $\phi : X \to V$ is a function, we are led to look at the special properties of convex sets, as in 463F. There are obvious connexions with the theory of measures on linear topological spaces, which I will come to in §466.

The dichotomy in 463J shows that sets of measurable functions on perfect measure spaces are either 'good' (relatively countably compact for $\mathfrak{T}_p$, relatively compact for $\mathfrak{T}_m$) or 'bad' (with neither property). It is known that the result is not true for arbitrary σ-finite measure spaces (see §464 below), but it is not clear whether there are important non-perfect spaces in which it still applies in some form; see 463Zb.

Just as in §462, many questions concerning the topology $\mathfrak{T}_p$ on $\mathbb{R}^X$ can be re-phrased as questions about real-valued functions on products $X \times K$ which are continuous in the second variable. For the topology of pointwise convergence on sets of measurable functions, we find ourselves looking at functions which are measurable in the first variable. In this way we are led to such results as 463L-463M and 463Ye. Concerning 463L and 463Zc, R.Pol has recently (June 2000) proved that if X and Y are *any* compact Hausdorff spaces, and $f : X \times Y \to \mathbb{R}$ is separately continuous, then f is Borel measurable.

A substantial proportion of the questions which arise naturally in this topic are known to be undecidable without using special axioms. I am avoiding such questions in this volume, but it is worth noting that the continuum hypothesis, in particular, has many striking consequences here, of which 463Ye is a sample. It also decides 463Za and 463Zb (see 463Yd).

464 Talagrand's measure

An obvious question arising from 463H and its corollaries is, do we really need the hypothesis that the measure involved is perfect? A very remarkable construction of M.Talagrand (464C) shows that these results are certainly not true of all probability spaces (464D). Investigating the properties of this measure we are led to some surprising facts about additive functionals on algebras $\mathcal{P}I$ and the duals of ℓ^∞ spaces (464M, 464R).

464A The usual measure on $\mathcal{P}I$ Recall from 254J and 416U that for any set I we have a standard measure ν, a Radon measure for the usual topology on $\mathcal{P}I$, defined by saying that $\nu\{a : a \subseteq I,\, a \cap J = c\} = 2^{-\#(J)}$ whenever $J \subseteq I$ is a finite set and $c \subseteq J$, or by copying from the usual product measure on $\{0,1\}^I$ by means of the bijection $a \mapsto \chi a : \mathcal{P}I \to \{0,1\}^I$. We shall need a couple of simple facts about these measures.

(a) If $\langle I_j\rangle_{j\in J}$ is any partition of I, then ν can be identified with the product of the family $\langle \nu_j\rangle_{j\in J}$, where ν_j is the usual measure on $\mathcal{P}I_j$, and we identify $\mathcal{P}I$ with $\prod_{j\in J}\mathcal{P}I_j$ by matching $a \subseteq I$ with $\langle a\cap I_j\rangle_{j\in J}$; this is the 'associative law' 254N. It follows that if we have any family $\langle A_j\rangle_{j\in J}$ of subsets of $\mathcal{P}I$, and if for each j the set A_j is 'determined by coordinates in I_j' in the sense that, for $a \subseteq I$, $a \in A_j$ iff $a \cap I_j \in A_j$, then $\nu^*(\bigcap_{j\in J} A_j) = \prod_{j\in J}\nu^* A_j$ (use 254Lb).

(b) Similarly, if f_1, f_2 are non-negative real-valued functions on $\mathcal{P}I$, and if there are disjoint sets I_1, $I_2 \subseteq I$ such that $f_j(a) = f_j(a \cap I_j)$ for every $a \subseteq I$ and both j, then the upper integral $\overline{\int} f_1 + f_2 d\nu$ is $\overline{\int} f_1 d\nu + \overline{\int} f_2 d\nu$. **P** We may suppose that $I_2 = I \setminus I_1$. For each j, define $g_j : \mathcal{P}I_j \to [0,\infty[$ by setting $g_j = f_j \restriction \mathcal{P}I_j$, so that $f_j(a) = g_j(a \cap I_j)$ for every $a \subseteq I$. Let ν_j be the usual measure on $\mathcal{P}I_j$, so that we can identify ν with the produce measure $\nu_1 \times \nu_2$, if we identify $\mathcal{P}I$ with $\mathcal{P}I_1 \times \mathcal{P}I_2$; that is, we think of a subset of I as a pair (a_1, a_2) where $a_j \subseteq I_j$ for both j.

Now we have

$$\begin{aligned}\overline{\int} f_1 + f_2\, d\nu &= \overline{\int} g_1\, d\nu_1 + \overline{\int} g_2\, d\nu_2 \\ \text{(by 253K)}\quad &= \overline{\int} g_1\, d\nu_1 \cdot \overline{\int} \mathbf{1} d\nu_2 + \overline{\int} \mathbf{1} d\nu_1 \cdot \overline{\int} g_2\, d\nu_2 \\ &= \overline{\int} f_1\, d\nu + \overline{\int} f_2\, d\nu\end{aligned}$$

by 253J, because we can think of $f_1(a_1, a_2)$ as $g_1(a_1)\mathbf{1}(a_2)$ for all a_1, a_2. **Q**

(c) If $A \subseteq \mathcal{P}I$ is such that $b \in A$ whenever $a \in A$, $b \subseteq I$ and $a \triangle b$ is finite, then $\nu^* A$ must be either 0 or 1; this is the zero-one law 254Sa, applied to the set $\{\chi a : a \in A\} \subseteq \{0,1\}^I$ and the usual measure on $\{0,1\}^I$.

464B Lemma Let I be any set, and ν the usual measure on $\mathcal{P}I$.

(a)(i) There is a sequence $\langle m(n)\rangle_{n\in\mathbb{N}}$ in $\mathbb{N}$ such that $\prod_{n=0}^{\infty} 1-2^{-m(n)} = \frac{1}{2}$.

(ii) Given such a sequence, write X for $\prod_{n\in\mathbb{N}}(\mathcal{P}I)^{m(n)}$, and let λ be the product measure on X. We have a function $\phi : X \to \mathcal{P}I$ defined by setting

$$\phi(\langle\langle a_{ni}\rangle_{i<m(n)}\rangle_{n\in\mathbb{N}}) = \bigcup_{n\in\mathbb{N}}\bigcap_{i<m(n)} a_{ni}$$

whenever $\langle\langle a_{ni}\rangle_{i<m(n)}\rangle_{n\in\mathbb{N}} \in X$. Now ϕ is inverse-measure-preserving for λ and ν.

(b) The map

$$(a,b,c) \mapsto (a\cap b)\cup(a\cap c)\cup(b\cap c) : (\mathcal{P}I)^3 \to \mathcal{P}I$$

is inverse-measure-preserving for the product measure on $(\mathcal{P}I)^3$.

proof (a)(i) Choose $m(n)$ inductively so that, for each n in turn, $m(n)$ is minimal subject to the requirement $\prod_{k=0}^{n} 1-2^{-m(k)} > \frac{1}{2}$.

(ii) If $t \in I$, then

$$\{\mathfrak{x} : \mathfrak{x}\in X,\ t\notin\phi(\mathfrak{x})\} = \{\langle\langle a_{ni}\rangle_{i<m(n)}\rangle_{n\in\mathbb{N}} : t\notin\bigcup_{n\in\mathbb{N}}\bigcap_{i<m(n)} a_{ni}\}$$

has measure

$$\prod_{n=0}^{\infty}\lambda_n\{\langle a_i\rangle_{i<m(n)} : t\notin\bigcap_{i<m(n)} a_i\},$$

where λ_n is the product measure on $(\mathcal{P}I)^{m(n)}$ for each n. But this is just

$$\prod_{n=0}^{\infty} 1-2^{-m(n)} = \frac{1}{2},$$

by the choice of $\langle m(n)\rangle_{n\in\mathbb{N}}$. Accordingly $\lambda\{\mathfrak{x} : t\in\phi(\mathfrak{x})\} = \frac{1}{2}$ for every $t\in I$. Next, each set $E_t = \{\mathfrak{x} : t\in\phi(\mathfrak{x})\}$ is determined by coordinates in $J_t = \{(t,n,i) : n\in\mathbb{N},\ i<m(n)\}$. Since the sets J_t are disjoint, the sets E_t, for different t, are stochastically independent (464Aa), so if $J\subseteq I$ is finite,

$$\lambda\{\mathfrak{x} : J\subseteq\phi(\mathfrak{x})\} = \prod_{t\in J}\lambda E_t = 2^{-\#(J)} = \nu\{a : J\subseteq a\}.$$

This shows that $\lambda\phi^{-1}[F] = \nu F$ whenever F is of the form $\{a : J\subseteq a\}$ for some finite $J\subseteq I$. By the Monotone Class Theorem (136B), $\lambda\phi^{-1}[F] = \nu F$ for every F belonging to the σ-algebra generated by sets of this form. But this σ-algebra certainly contains all sets of the form $\{a : a\cap J = c\}$ where $J\subseteq I$ is finite and $c\subseteq J$, which are the sets corresponding to the basic cylinder sets in the product $\{0,1\}^I$. By 254G, ϕ is inverse-measure-preserving.

(b) This uses the same idea as (a-ii). Writing ν^3 for the product measure on $(\mathcal{P}I)^3$, then, for any $t\in I$,

$$\begin{aligned}\nu^3\{(a,b,c) : t\in(a\cap b)\cup(a\cap c)\cup(b\cap c)\}&\\ &= \nu^3\{(a,b,c) : t\in a\cap b\} + \nu^3\{(a,b,c) : t\in a\cap c\}\\ &\qquad + \nu^3\{(a,b,c) : t\in b\cap c\} - 2\nu^3\{(a,b,c) : t\in a\cap b\cap c\}\\ &= 3\cdot\frac{1}{4} - 2\cdot\frac{1}{8} = \frac{1}{2}.\end{aligned}$$

Once again, these sets are independent for different t, and this is all we need to know in order to be sure that the map is inverse-measure-preserving.

464C Lemma Let I be any set, and let ν be the usual measure on $\mathcal{P}I$.

(a) (see Sierpiński 45) If $\mathcal{F}\subseteq\mathcal{P}I$ is any filter containing every cofinite set, then $\nu_*\mathcal{F} = 0$ and $\nu^*\mathcal{F}$ is either 0 or 1. If $\mathcal{F}$ is a non-principal ultrafilter then $\nu^*\mathcal{F} = 1$.

(b) (Talagrand 80[3]) If $\langle\mathcal{F}_n\rangle_{n\in\mathbb{N}}$ is a sequence of filters on I, all of outer measure 1, then $\bigcap_{n\in\mathbb{N}}\mathcal{F}_n$ also has outer measure 1.

[3]The date of this paper is misleading, as there was an unusual backlog in the journal; in reality it preceded Fremlin & Talagrand 79.

proof (a) That $\nu^*\mathcal{F} \in \{0,1\}$ is immediate from 464Ac. If $\mathcal{F}$ is an ultrafilter, then $\mathcal{P}I = \mathcal{F} \cup \{I \setminus a : a \in \mathcal{F}\}$; but as $a \mapsto I \setminus a$ is a measure space automorphism of $(\mathcal{P}I, \nu)$, $\nu^*\{I \setminus a : a \in \mathcal{F}\} = \nu^*\mathcal{F}$, and both must be at least $\frac{1}{2}$, so $\nu^*\mathcal{F} = 1$. Equally, $\nu^*(\mathcal{P}I \setminus \mathcal{F}) = \nu^*\{I \setminus a : a \in \mathcal{F}\} = 1$, so $\nu_*\mathcal{F} = 0$. Returning to a general filter containing every cofinite set, this is included in a non-principal ultrafilter, so also has inner measure 0.

(b) Let $\langle m(n)\rangle_{n\in\mathbb{N}}$ be a sequence in $\mathbb{N}$ such that $\prod_{n=0}^{\infty} 1 - 2^{-m(n)} = \frac{1}{2}$, and let X, λ and $\phi : X \to \mathcal{P}I$ be as in 464Ba. Consider the set $D = \prod_{n\in\mathbb{N}} \mathcal{F}_n^{m(n)}$ as a subset of X. By 254Lb, $\lambda^* D = 1$. If we set $\mathcal{F} = \bigcap_{n\in\mathbb{N}} \mathcal{F}_n$, then we see that whenever $\mathfrak{x} = \langle\langle a_{ni}\rangle_{i<m(n)}\rangle_{n\in\mathbb{N}}$ belongs to D,

$$\phi(\mathfrak{x}) \supseteq \textstyle\bigcap_{i<m(n)} a_{ni} \in \mathcal{F}_n$$

for every n, so that $\phi(\mathfrak{x}) \in \mathcal{F}$. Thus $D \subseteq \phi^{-1}[\mathcal{F}]$ and

$$\nu^*\mathcal{F} \geq \lambda^*\phi^{-1}[\mathcal{F}] \geq \lambda^* D = 1$$

because ϕ is inverse-measure-preserving (413Eh).

As $\langle\mathcal{F}_n\rangle_{n\in\mathbb{N}}$ is arbitrary, we have the result.

464D Construction (Talagrand 80) Let I be any set, and ν the usual Radon measure on $\mathcal{P}I$, with T its domain. Let Σ be the set

$$\{E : E \subseteq \mathcal{P}I, \text{ there are a set } F \in \mathrm{T} \text{ and a filter } \mathcal{F} \text{ on } I \text{ such that } \nu^*\mathcal{F} = 1 \text{ and } E \cap \mathcal{F} = F \cap \mathcal{F}\}.$$

Then there is a unique extension of ν to a complete probability measure μ, with domain Σ, defined by saying that $\mu E = \nu F$ whenever $E \in \Sigma$, $F \in \mathrm{T}$ and there is a filter $\mathcal{F}$ on I such that $\nu^*\mathcal{F} = 1$ and $E \cap \mathcal{F} = F \cap \mathcal{F}$. (Apply 417A with

$$\mathcal{A} = \{\mathcal{P}I \setminus \mathcal{F} : \mathcal{F} \text{ is a filter on } I \text{ such that } \nu^*\mathcal{F} = 1\}.)$$

Definition This measure μ is **Talagrand's measure** on $\mathcal{P}I$.

464E Example If μ is Talagrand's measure on $X = \mathcal{P}\mathbb{N}$, and Σ its domain, then there is a set $K \subseteq \mathbb{R}^X$, consisting of Σ-measurable functions and compact for the topology $\mathfrak{T}_p$ of pointwise convergence, such that K is not compact for the topology of convergence in measure, that is, there is a sequence in K with no subsequence which is convergent almost everywhere, even though every cluster point is Σ-measurable.

proof Take K to be $\{\chi\mathcal{F} : \mathcal{F} \text{ is an ultrafilter on } \mathbb{N}\}$. Then K is $\mathfrak{T}_p$-compact (in fact, is precisely the set of Boolean homomorphisms from $\mathcal{P}\mathbb{N}$ to $\{0,1\}$, identified with the Stone space of $\mathcal{P}\mathbb{N}$ in §311). By 464Ca, we see that any non-principal ultrafilter $\mathcal{F}$ on $\mathbb{N}$ belongs to Σ, and $\mu\mathcal{F} = 1$. On the other hand, all the principal ultrafilters $\mathcal{F}_n = \{a : n \in a \subseteq \mathbb{N}\}$ are measured by ν and therefore by μ, and form a stochastically independent sequence of sets of measure $\frac{1}{2}$. So K consists of Σ-measurable functions; but the sequence $\langle\chi F_n\rangle_{n\in\mathbb{N}}$ has no subsequence which is convergent almost everywhere, and K is not relatively compact for the topology of convergence in measure.

Remark In this example, a very large number of members of K are equal almost everywhere; indeed, all non-principal ultrafilters are equal a.e., and if we look at $\{f^\bullet : f \in K\}$ in $L^0(\mu)$, it is a countable discrete set. Given that K is a set of measurable functions homeomorphic to $\beta\mathbb{N}$, something like this has to happen (463L-463M). Looking at this from a different angle, if we wish to extend the usual measure ν on $\mathcal{P}\mathbb{N}$ to measure every ultrafilter, there will have to be two distinct ultrafilters $\mathcal{F}_1$, $\mathcal{F}_2$ such that $\mathcal{F}_1 \triangle \mathcal{F}_2$ is negligible for the extended measure.

464F The L-space $\ell^\infty(I)^*$ For the next step, we shall need to recall some facts from Volume 3. Let I be any set.

(a) The space $\ell^\infty(I)$ of bounded real-valued functions on I is an M-space (354Ha), so its dual $\ell^\infty(I)^\sim = \ell^\infty(I)^*$ is an L-space (356N), that is, a Banach lattice such that $\|f + g\| = \|f\| + \|g\|$ for all non-negative f, $g \in \ell^\infty(I)^*$. Since $\ell^\infty(I)$ can be identified with the space $L^\infty(\mathcal{P}I)$ as described in §363 (see 363Ha), we can identify $\ell^\infty(I)^*$ with the L-space M of bounded finitely additive functionals on $\mathcal{P}I$ (363K), matching any $f \in \ell^\infty(I)^*$ with the functional $a \mapsto f(\chi a) : \mathcal{P}I \to \mathbb{R}$ in M.

(b) In §§361-363 I examined some of the bands in M. The most significant ones for our present purposes are the band M_τ of completely additive functionals (362Bb) and its complement $M_\tau^\perp$ (352P); because M is Dedekind complete, we have $M = M_\tau \oplus M_\tau^\perp$ (353I). In fact M_τ is just the set of those $\theta \in M$ such that $\theta a = \sum_{t\in a} \theta\{t\}$ for every $a \subseteq I$, while $M_\tau^\perp$ is the set of those $\theta \in M$ such that $\theta\{t\} = 0$ for every $t \in I$. **P** For any $\theta \in M$, we can set $\alpha_t = \theta\{t\}$ for each $t \in I$; in this case,

$$|\textstyle\sum_{t\in J} \alpha_t| = |\theta J| \leq \|\theta\|$$

for every finite set $J \subseteq I$, so $\sum_{t\in I} |\alpha_t|$ is finite, and we have a functional θ_1 defined by setting $\theta_1 a = \sum_{t\in a} \alpha_t$ for every $a \subseteq I$. It is easy to check that $\theta_1 \in M_\tau$. If we write $\theta_2 = \theta - \theta_1$ then $\theta_2\{t\} = 0$ for every $t \in I$. So if $\phi \in M_\tau$ and $0 \leq \phi \leq |\theta_2|$, we still have $\phi\{t\} = 0$ for every $t \in I$, and $\phi a = 0$ for every finite $a \subseteq I$ and $\phi = 0$; thus $\theta_2 \in M_\tau^\perp$. Now $\theta \in M_\tau$ iff $\theta_2 = 0$, that is, iff $\theta = \theta_1$ and $\theta a = \sum_{t\in a} \theta\{t\}$ for every $a \subseteq I$; while $\theta \in M_\tau^\perp$ iff $\theta_1 = 0$, that is, $\theta\{t\} = 0$ for every $t \in I$. **Q**

Observe that if $\theta \in M_\tau^\perp$ and a, $b \subseteq I$ are such that $a \triangle b$ is finite, then $\theta a = \theta b$, because $\theta(a \setminus b) = \theta(b \setminus a) = 0$.

(c) It will be useful to have an elementary fact out in the open. If $\theta \in M^+$, then $\{a : a \subseteq I, \theta a = \theta I\}$ is a filter; this is because $\{a : \theta a = 0\}$ is an ideal in $\mathcal{P}I$.

464G We also need a new result not exactly covered by those in Chapters 35 and 36.

Lemma Let $\mathfrak{A}$ be any Boolean algebra. Write M for the L-space of bounded additive functionals on $\mathfrak{A}$, and M^+ for its positive cone, the set of non-negative additive functionals. Suppose that $\Delta : M^+ \to [0, \infty[$ is a functional such that

(α) Δ is non-decreasing,

(β) $\Delta(\alpha\theta) = \alpha\Delta(\theta)$ whenever $\theta \in M^+$, $\alpha \geq 0$,

(γ) $\Delta(\theta_1 + \theta_2) = \Delta(\theta_1) + \Delta(\theta_2)$ whenever θ_1, $\theta_2 \in M^+$ are such that, for some $e \subseteq I$, $\theta_1(1 \setminus e) = \theta_2 e = 0$,

(δ) $|\Delta(\theta_1) - \Delta(\theta_2)| \leq \|\theta_1 - \theta_2\|$ for all θ_1, $\theta_2 \in M^+$.

Then there is a non-negative $h \in M^*$ extending Δ.

proof (a) If θ_1, $\theta_2 \in M^+$ are such that $\theta_1 \wedge \theta_2 = 0$ in M^+, then $\Delta(\theta_1 + \theta_2) = \Delta(\theta_1) + \Delta(\theta_2)$. **P** Let $\epsilon > 0$. Then there is an $e \in \mathfrak{A}$ such that $\theta_1(1 \setminus e) + \theta_2 e \leq \epsilon$ (362Ba). Set $\theta_1' a = \theta_1(a \cap e)$, $\theta_2'(a) = \theta_2(a \setminus e)$ for $a \in \mathfrak{A}$; then θ_1' and θ_2' belong to M^+ and $\theta_1'(1 \setminus e) = \theta_2' e = 0$, so $\Delta(\theta_1' + \theta_2') = \Delta(\theta_1') + \Delta(\theta_2')$, by hypothesis ($\gamma$). On the other hand,

$$0 \leq \theta_1 a - \theta_1' a = \theta(a \setminus e) \leq \theta(1 \setminus e) \leq \epsilon$$

for every $a \in \mathfrak{A}$, so $\|\theta_1 - \theta_1'\| \leq \epsilon$. Similarly, $\|\theta_2 - \theta_2'\| \leq \epsilon$ and $\|(\theta_1 + \theta_2) - (\theta_1' - \theta_2')\| \leq 2\epsilon$. But this means that we can use the hypothesis (δ) to see that

$$|\Delta(\theta_1 + \theta_2) - \Delta(\theta_1) - \Delta(\theta_2)| \leq |\Delta(\theta_1' + \theta_2') - \Delta(\theta_1') - \Delta(\theta_2')| + 4\epsilon = 4\epsilon.$$

As ϵ is arbitrary, $\Delta(\theta_1 + \theta_2) = \Delta(\theta_1) + \Delta(\theta_2)$. **Q**

(b) Now recall that M, being a Dedekind complete Riesz space, can be identified with an order-dense solid linear subspace of $L^0(\mathfrak{C})$ for some Boolean algebra $\mathfrak{C}$ (368H). Inside $L^0(\mathfrak{C})$ we have the order-dense Riesz subspace $S(\mathfrak{C})$ (364K). Write S_1 for $M \cap S(\mathfrak{C})$, so that S_1 is an order-dense Riesz subspace of M (352N, 353A).

If θ_1, $\theta_2 \in S_1^+ = S_1 \cap M^+$, then $\Delta(\theta_1 + \theta_2) = \Delta(\theta_1) + \Delta(\theta_2)$. **P** We can express θ_1 as $\sum_{i=0}^m \alpha_i \chi c_i$, where $c_0, \ldots, c_m$ are disjoint members of $\mathfrak{C}$, and $\alpha_i \geq 0$ for each i (361Ec); adding a term $0 \cdot \chi(1 \setminus \sup_{i\leq m} c_i)$ if necessary, we may suppose that $\sup_{i\leq m} c_i = 1$. Similarly, we can express θ_2 as $\sum_{j=0}^n \beta_j \chi d_j$ where $d_0, \ldots, d_n \in \mathfrak{C}$ are disjoint, $\beta_j \geq 0$ for every j and $\sup_{j\leq n} d_j = 1$. In this case, $\theta_1 = \sum_{i\leq m, j\leq n} \alpha_i \chi(c_i \cap d_j)$ and $\theta_2 = \sum_{i\leq m, j\leq n} \beta_j \chi(c_i \cap d_j)$. Re-enumerating $\{c_i \cap d_j : i \leq m, j \leq n\}$ as $\langle e_i : i \leq k\}$ we have expressions of θ_1, θ_2 in the form $\sum_{i\leq k} \gamma_i \chi e_i$, $\sum_{i\leq k} \delta_i \chi e_i$, while $e_0, \ldots, e_k$ are disjoint.

Setting $\theta_1^{(r)} = \sum_{i=0}^r \gamma_i \chi e_i$ for $r \leq k$, we see that $\theta_1^{(r)} \wedge \gamma_{r+1} \chi e_{r+1} = 0$ for $r < k$, so (a) above, together with the hypothesis (β), tell us that

$$\Delta(\theta_1^{(r+1)}) = \Delta(\theta_1^{(r)}) + \Delta(\gamma_{r+1}\chi e_{r+1}) = \Delta(\theta_1^{(r)}) + \gamma_{r+1}\Delta(\chi e_{r+1})$$

for $r < k$. Accordingly $\Delta(\theta_1) = \sum_{i=0}^k \gamma_i \Delta(\chi e_i)$. Similarly, $\Delta(\theta_2) = \sum_{i=0}^k \delta_i \Delta(\chi e_i)$ and

$$\Delta(\theta_1 + \theta_2) = \sum_{i=0}^k (\gamma_i + \delta_i)\Delta(\chi e_i) = \Delta(\theta_1) + \Delta(\theta_2),$$

as claimed. **Q**

(c) Consequently, $\Delta(\theta_1+\theta_2) = \Delta(\theta_1)+\Delta(\theta_2)$ for all $\theta_1, \theta_2 \in M^+$. **P** Let $\epsilon > 0$. Because S_1 is order-dense in M, and the norm of M is order-continuous (354N), S_1 is norm-dense (354Ef), and there are $\theta_1', \theta_2' \in S_1^+$ such that $\|\theta_j - \theta_j'\| \leq \epsilon$ for both j (354Be). But now, just as in (a),

$$|\Delta(\theta_1 + \theta_2) - \Delta(\theta_1) - \Delta(\theta_2)| \leq |\Delta(\theta_1' + \theta_2') - \Delta(\theta_1') - \Delta(\theta_2')| + 4\epsilon = 4\epsilon.$$

As ϵ is arbitrary, we have the result. **Q**

(d) Now (c) and the hypothesis (β) are sufficient to ensure that Δ has an extension to a positive linear functional (355D).

464H The next lemma contains the key ideas needed for the rest of the section.

Lemma Let I be any set, and M the L-space of bounded additive functionals on $\mathcal{P}I$; let ν be the usual measure on $\mathcal{P}I$. For $\theta \in M^+$, set

$$\Delta(\theta) = \overline{\int} \theta \, d\nu.$$

(a) For every $\theta \in M^+$, $\frac{1}{2}\theta I \leq \Delta(\theta) \leq \theta I$.

(b) There is a non-negative $h \in M^*$ such that $h(\theta) = \Delta(\theta)$ for every $\theta \in M^+$.

(c) If $\theta \in (M_\tau^\perp)^+$, where $M_\tau \subseteq M$ is the band of completely additive functionals, then $\theta \leq \Delta(\theta)$ ν-a.e., and $\nu^*\{a : \alpha \leq \theta a \leq \Delta(\theta)\} = 1$ for every $\alpha < \Delta(\theta)$.

(d) Suppose that $\theta \in (M_\tau^\perp)^+$ and $\beta, \gamma \in [0,1]$ are such that $\theta I = 1$ and $\beta\theta' I \leq \Delta(\theta') \leq \gamma\theta' I$ whenever $\theta' \leq \theta$ in M^+. Then, for any $\alpha < \beta$,

(i) for any finite set $K \subseteq \mathcal{P}I$, the set

$$Q_K = \{a : a \subseteq I, \, \alpha\theta b \leq \theta(a \cap b) \leq \gamma\theta b \text{ for every } b \in K\}$$

has outer measure 1 in $\mathcal{P}I$;

(ii) if $\alpha \geq \frac{1}{2}$, the set

$$R = \{(a,b,c) : a, \, b, \, c \subseteq I, \, \theta((a \cap b) \cup (a \cap c) \cup (b \cap c)) \geq 2\alpha^2 + (1-2\alpha)\gamma^2\}$$

has outer measure 1 in $(\mathcal{P}I)^3$;

(iii) if $\alpha \geq \frac{1}{2}$, then $2\alpha^2 + (1-2\alpha)\gamma^2 \leq \gamma$.

(e) Any $\theta \in M^+$ can be expressed as $\theta_1 + \theta_2$ where $\Delta(\theta_1) = \frac{1}{2}\theta_1 I$ and $\Delta(\theta_2) = \theta_2 I$.

(f) Suppose that $0 \leq \theta' \leq \theta$ in M.

(i) If $\Delta(\theta) = \frac{1}{2}\theta I$, then $\Delta(\theta') = \frac{1}{2}\theta' I$.

(ii) If $\Delta(\theta) = \theta I$, then $\Delta(\theta') = \theta' I$.

proof (a) Of course

$$\Delta(\theta) \leq \int \theta I \, d\nu = \theta I.$$

On the other hand, because $a \mapsto I \setminus a : \mathcal{P}I \to \mathcal{P}I$ is an automorphism of the measure space $(\mathcal{P}I, \nu)$, $\overline{\int} f(I \setminus a)\nu(da) = \overline{\int} f(a)\nu(da)$ for any real-valued function f. In particular,

$$\Delta(\theta) = \overline{\int} \theta(a)\nu(da) = \overline{\int} \theta(I \setminus a)\nu(da).$$

So

$$2\Delta(\theta) = \overline{\int} \theta(a)\nu(da) + \overline{\int} \theta(I \setminus a)\nu(da) \geq \overline{\int} \theta(a) + \theta(I \setminus a)\nu(da)$$

(133J(b-ii))

$$= \overline{\int} \theta I \, \nu(da) = \theta I,$$

and $\Delta(\theta) \geq \frac{1}{2}\theta I$.

(b) I use 464G with $\mathfrak{A} = \mathcal{P}I$. Examine the conditions (α)-(δ) there.

(α) Of course Δ is non-decreasing (133Jc).

(β) $\Delta(\alpha\theta) = \alpha\Delta(\theta)$ for every $\theta \in M^+$ and every $\alpha \geq 0$, by 133J(b-iii).

(γ) If θ_1, $\theta_2 \in M^+$ then $\Delta(\theta_1 + \theta_2) \leq \Delta(\theta_1) + \Delta(\theta_2)$ by 133J(b-ii), as in (a). If θ_1, $\theta_2 \in M^+$ and $e \subseteq I$ are such that $\theta_1(I \setminus e) = \theta_2 e = 0$, then $\theta_1 a = \theta_1(a \cap e)$, $\theta_2(a) = \theta_2(a \setminus e)$ for every $a \subseteq I$. So $\Delta(\theta_1 + \theta_2) = \Delta(\theta_1) + \Delta(\theta_2)$ by 464Ab.

(δ) For every $a \subseteq I$, $\theta_2 a \leq \theta_1 a + \|\theta_2 - \theta_1\|$, so $\Delta(\theta_2) \leq \Delta(\theta_1) + \|\theta_2 - \theta_1\|$. Similarly, $\Delta(\theta_1) \leq \Delta(\theta_2) + \|\theta_1 - \theta_2\|$. So $|\Delta(\theta_1) - \Delta(\theta_2)| \leq \|\theta_1 - \theta_2\|$, and Δ satisfies condition (δ) of 464G.

(ϵ) Accordingly 464G tells us that Δ has an extension to a member of M^*.

(c) If $\theta \in M_\tau^\perp$, then $\theta a = \theta b$ whenever $a \triangle b$ is finite (464Fb), so all the sets $\{a : \theta a > \alpha\}$ have outer measure either 0 or 1, by 464Ac. But this means that if f is a measurable function and $\theta \leq_{\text{a.e.}} f$ and $\int f = \Delta(\theta)$, as in 133Ja, $\{a : f(a) \leq \Delta(\theta)\}$ has positive measure and meets $A = \{a : \theta a > \Delta(\theta)\}$ in a negligible set; so A cannot have full outer measure and is negligible.

On the other hand, if $\alpha < \Delta(\theta)$, then θ cannot be dominated a.e. by $\alpha\mathbf{1}$, so $\{a : \theta a > \alpha\}$ is not negligible and has outer measure 1.

(d)(i) The point is just that for any $b \subseteq I$, the functional θ_b, defined by saying that $\theta_b(a) = \theta(a \cap b)$ for every $a \subseteq I$, belongs to M^+ and is dominated by θ, so that $\beta\theta_b I \leq \Delta(\theta_b) \leq \gamma\theta_b I$, and $\{a : \alpha\theta_b I \leq \theta_b a \leq \gamma\theta_b I\}$ has outer measure 1, by (c). (If $\alpha\theta_b I = \Delta(\theta_b)$, this is because $\theta_b I = 0$, and the result is trivial; otherwise, $\alpha\theta_b I < \Delta(\theta_b) \leq \gamma\theta_b I$.) But this just says that, for any $b \subseteq I$,

$$\{a : \alpha\theta b \leq \theta(a \cap b) \leq \gamma\theta b\}$$

has outer measure 1.

Now, given any finite set $K \subseteq \mathcal{P}I$, let $\mathcal{B}$ be the subalgebra of $\mathcal{P}I$ generated by K, and $b_0, \ldots, b_n$ the atoms of $\mathcal{B}$. Then all the sets

$$A_i = \{a : \alpha\theta b_i \leq \theta(a \cap b_i) \leq \gamma\theta b_i\}$$

have outer measure 1; because each A_i is determined by coordinates in b_i, and $b_0, \ldots, b_n$ are disjoint, $A = \bigcap_{i \leq n} A_i$ still has outer measure 1, by 464Aa. But if $a \in A$ and $b \in K$, then $b = \bigcup_{i \in J} b_i$ for some $J \subseteq \{0, \ldots, n\}$ and

$$\begin{aligned}\alpha\theta b &= \sum_{i \in J} \alpha\theta b_i \leq \sum_{i \in J} \theta(a \cap b_i) \\ &= \theta(a \cap b) \leq \sum_{i \in J} \gamma\theta b_i = \gamma\theta b.\end{aligned}$$

So $\{a : \alpha\theta b \leq \theta(a \cap b) \leq \gamma\theta b \text{ for every } b \in K\}$ includes A and has outer measure 1.

(ii) ? Suppose, if possible, otherwise; then $\nu^3_*(\mathcal{P}I \setminus R) > 0$, where ν^3 is the product measure on $(\mathcal{P}I)^3$, and there is a measurable set $W \subseteq (\mathcal{P}I)^3 \setminus R$ such that $\nu^3 W > 0$. For $a \subseteq I$, set $W_a = \{(b, c) : (a, b, c) \in W\}$; then $\nu^3 W = \int \nu^2 W_a \nu(da)$, where ν^2 is the product measure on $(\mathcal{P}I)^2$, by Fubini's theorem (252D). Set $E = \{a : \nu^2 W_a \text{ is defined and not zero}\}$; then $\nu E > 0$. Since $\{a : \alpha \leq \theta a \leq \gamma\}$ has outer measure 1, there is an $a \in E$ such that $\alpha \leq \theta a \leq \gamma$.

For $b \subseteq I$, set $W_{ab} = \{c : (b, c) \in W_a\} = \{c : (a, b, c) \in W\}$. Then $0 < \nu^2 W_a = \int \nu W_{ab} \nu(db)$, so $F = \{b : \nu W_{ab} \text{ is defined and not } 0\}$ has non-zero measure. But also, by (i),

$$\{b : \theta b \geq \alpha, \, \theta(a \cap b) \leq \gamma\theta a\}$$

has outer measure 1, so we can find a $b \in F$ such that $\theta b \geq \alpha$ and $\theta(a \cap b) \leq \gamma\theta a$.

By (i) again,

$$\{c : \theta(c \cap (a \triangle b)) \geq \alpha\theta(a \triangle b)\}$$

has outer measure 1, so meets W_{ab}; accordingly we have a $c \subseteq I$ such that $(a, b, c) \in W$ while $\theta(c \cap (a \triangle b)) \geq \alpha\theta(a \triangle b)$.

Now calculate, for this triple (a, b, c),

$$\theta((a \cap b) \cup (a \cap c) \cup (b \cap c)) = \theta(a \cap b) + \theta(c \cap (a \triangle b)) \geq \theta(a \cap b) + \alpha\theta(a \triangle b)$$

(by the choice of c)

$$= \alpha(\theta a + \theta b) + (1 - 2\alpha)\theta(a \cap b)$$
$$\geq \alpha(\theta a + \alpha) + (1 - 2\alpha)\gamma\theta a$$

(by the choice of b, recalling that $1 - 2\alpha \leq 0$)

$$\geq 2\alpha^2 + (1 - 2\alpha)\gamma^2$$

by the choice of a. But this means that $(a, b, c) \in W \cap R$, which is supposed to be impossible. **X**

(iii) Now recall that the map $(a, b, c) \mapsto (a \cap b) \cup (a \cap c) \cup (b \cap c)$ is inverse-measure-preserving (464Ac). Since $\theta a \leq \Delta(\theta) \leq \gamma$ for ν-almost every a, we must have $\theta((a \cap b) \cup (a \cap c) \cup (b \cap c)) \leq \gamma$ for ν^3-almost every (a, b, c). But as R is not negligible, there must be some $(a, b, c) \in R$ such that $\theta((a \cap b) \cup (a \cap c) \cup (b \cap c)) \leq \gamma$, and $2\alpha^2 + (1 - 2\alpha)\gamma^2 \leq \gamma$.

(e)(i) M^*, being the dual of an L-space, is an M-space (356P), so can be represented as $C(Z)$ for some compact Hausdorff space Z (354L). The functional h of (b) above therefore corresponds to a function $w \in C(Z)$. Any $\theta \in M^+$ acts on M^* as a positive linear functional, so corresponds to a Radon measure μ_θ on Z (436J/436K); we have $\Delta(\theta) = h(\theta) = \int w \, d\mu_\theta$. The inequalities $\frac{1}{2}\theta I \leq \Delta(\theta) \leq \theta I$ become $\frac{1}{2}\mu_\theta Z \leq \int w \, d\mu_\theta \leq \mu_\theta Z$, because the constant function χZ corresponds to the standard order unit of M^* (356P), so that

$$\mu_\theta Z = \int \chi Z \, d\mu_\theta = \|\theta\| = \theta I$$

for every $\theta \geq 0$. Since $0 \leq h(\theta) \leq \|\theta\|$ for every $\theta \geq 0$, $\|w\|_\infty = \|h\| \leq 1$ and $0 \leq w \leq \chi Z$.

(ii) Now suppose that $\beta < \gamma$ and that $G = \{z : z \in Z, \beta < w(z) < \gamma\}$ is non-empty. In this case there is a non-zero $\theta_0 \in M^+$ such that $\beta\theta' I \leq \Delta(\theta') \leq \gamma\theta' I$ whenever $0 \leq \theta' \leq \theta_0$.

P(α) We have a solid linear subspace $V = \{v : v \in C(Z), v(z) = 0 \text{ for every } z \in G\}$ of $C(Z)$. Consider $U = \{\theta : \theta \in M, (\theta|v) = 0 \text{ for every } v \in V\}$, where I write $(\,|\,)$ for the duality between M and $C(Z)$ corresponding to the identification of $C(Z)$ with M^*.

(β) If $\theta \in U \cap M^+$, then $\beta\theta I \leq \Delta(\theta) \leq \gamma\theta I$. To see this, observe that $\int v \, d\mu_\theta = (\theta|v) = 0$ for every $v \in V$, so

$$\mu_\theta(Z \setminus \overline{G}) = \sup\{\mu_\theta K : K \subseteq Z \setminus \overline{G} \text{ is compact}\}$$
$$= \sup\{\int v \, d\mu_\theta : v \in C(Z), 0 \leq v \leq \chi(Z \setminus \overline{G})\}$$

(because Z is normal, so that whenever $K \subseteq Z \setminus \overline{G}$ is compact there is a $v \in C(Z)$ such that $\chi K \leq v \leq \chi(Z \setminus \overline{G})$, by Urysohn's Lemma)

$$= 0.$$

Accordingly $\beta < w < \gamma$ μ_θ-a.e. and $\int w \, d\mu_\theta$ must lie between $\beta\mu_\theta Z = \beta\theta I$ and $\gamma\mu_\theta Z = \gamma\theta I$.

(γ) Because M is an L-space, it is perfect (356P), so its dual $M^* = M^\times$ is also perfect, and $C(Z)$ is perfect; moreover, the duality $(\,|\,)$ identifies M with $C(Z)^\times$. Now $V^\perp$, taken in $C(Z)$, contains any continuous function zero on $Z \setminus G$, so is not $\{0\}$; since $V^\perp$, like $C(Z)$, must be perfect (356L), $(V^\perp)^\times$ is non-trivial. Take any $\psi > 0$ in $(V^\perp)^\times$. Being perfect, $C(Z)$ is Dedekind complete (356K), so there is a band projection $P : C(Z) \to V^\perp$ (353I). Now ψP is a positive element of $C(Z)^\times$ which is zero on V, and must correspond to a non-zero element θ_0 of $U \cap M^+$.

($\boldsymbol{\delta}$) If $0 \leq \theta' \leq \theta_0$ in M, then, for any $v \in V$,

$$|(\theta'|v)| \leq (\theta'||v|) \leq (\theta_0||v|) = 0,$$

because $|v| \in V$. So $\theta' \in U$ and $\beta\theta' I \leq \Delta(\theta') \leq \gamma\theta' I$, by ($\beta$). Thus θ_0 has the required property. **Q**

(iii) It follows at once that $w(z) \geq \frac{1}{2}$ for every $z \in Z$. **P?** If $w(z_0) < \frac{1}{2}$, then we can apply (ii) with $\beta = -1$, $\gamma \in \left]w(z_0), \frac{1}{2}\right[$ to see that there is a non-zero $\theta \in M^+$ such that $\Delta(\theta) \leq \gamma\theta I < \frac{1}{2}\theta I$, which is impossible, by (a). **XQ**

(iv) But we find also that $w(z) \notin \left]\frac{1}{2}, 1\right[$ for any $z \in Z$. **P?** If $w(z_0) = \delta \in \left]\frac{1}{2}, 1\right[$, then $2\delta^2 + (1-2\delta)\delta^2 > \delta$ (because $\delta(2\delta-1)(1-\delta) > 0$). We can therefore find α, β and γ such that $\frac{1}{2} \leq \alpha < \beta < \delta < \gamma$ and $2\alpha^2 + (1-2\alpha)\gamma^2 > \gamma$. But now $\{z : \beta < w(z) < \gamma\}$ is non-empty, so by (ii) there is a non-zero $\theta \in M^+$ such that $\beta\theta' I \leq \Delta(\theta') \leq \gamma\theta' I$ whenever $0 \leq \theta' \leq \theta$. Multiplying θ by a suitable scalar if necessary, we can arrange that θI should be 1. But this is impossible, by (d-iii). **XQ**

(v) Thus w takes only the values $\frac{1}{2}$ and 1; let H_1 and H_2 be the corresponding open subsets of Z.

Take $\theta \in M^+$. For $u \in C(Z)$, set $\phi(u) = \int u \, d\mu_\theta$ and $\phi_j(u) = \int_{H_j} u \, d\mu_\theta$ for each j. Then each ϕ_j is a positive linear functional on $C(Z)$ and $\phi_j \leq \phi$. But ϕ is the image of θ under the canonical isomorphism from M to $C(Z)^\times \cong M^{\times\times}$, and $C(Z)^\times$ is solid in $C(Z)^\sim$ (356B), so both ϕ_1 and ϕ_2 belong to the image of M, and correspond to θ_1, $\theta_2 \in M$. For any $u \in C(Z)$,

$$(\theta_1 + \theta_2|u) = \phi_1(u) + \phi_2(u) = (\theta|u),$$

so $\theta = \theta_1 + \theta_2$. We have

$$\begin{aligned}\Delta(\theta_j) = \phi_j(w) &= \int_{H_j} w \, d\mu_\theta \\ &= \tfrac{1}{2}\mu_\theta(H_1) = \tfrac{1}{2}\theta_1 I \text{ if } j = 1, \\ &= \mu_\theta(H_2) = \theta_2 I \text{ if } j = 2.\end{aligned}$$

So we have a suitable decomposition $\theta = \theta_1 + \theta_2$.

(f) This is easy. Set $\theta'' = \theta - \theta'$; then

$$\tfrac{1}{2}\theta' I \leq \Delta(\theta') \leq \theta' I,$$

$$\tfrac{1}{2}\theta'' I \leq \Delta(\theta'') \leq \theta'' I$$

by (a), while $\Delta(\theta') + \Delta(\theta'') = \Delta(\theta)$ by (b), and of course $\theta' I + \theta'' I = \theta I$. But this means that

$$\Delta(\theta') - \tfrac{1}{2}\theta' I \leq \Delta(\theta) - \tfrac{1}{2}\theta I, \quad \theta' I - \Delta(\theta') \leq \theta I - \Delta(\theta),$$

and the results follow.

464I Measurable and purely non-measurable functionals As before, let I be any set, ν the usual measure on $\mathcal{P}I$, T its domain, and M the L-space of bounded additive functionals on $\mathcal{P}I$. Following Fremlin & Talagrand 79, I say that $\theta \in M$ is **measurable** if it is T-measurable when regarded as a real-valued function on $\mathcal{P}I$, and **purely non-measurable** if $\{a : a \subseteq I, |\theta|(a) = |\theta|(I)\}$ has outer measure 1. (Of course the zero functional is both measurable and purely non-measurable.)

464J Examples Before going farther, I had better offer some examples of measurable and purely non-measurable functionals. Let I, ν and M be as in 464I.

(a) Any $\theta \in M_\tau$ is measurable, where M_τ is the space of completely additive functionals on $\mathcal{P}I$. **P** By 464Fb, θ can be expressed as a sum of point masses; say $\theta a = \sum_{t \in a} \alpha_t$ for some family $\langle \alpha_t \rangle_{t \in I}$ in $\mathbb{R}$. Since $\sum_{t \in I} |\alpha_t|$ must be finite, $\{t : \alpha_t \neq 0\}$ is countable, and we can express θ as the limit of a sequence of finite sums $\sum_{t \in K} \alpha_t \hat{t}$, where $\hat{t}(a) = 1$ if $t \in a$, 0 otherwise. But of course every $\hat{t}$ is a measurable function, so $\sum_{t \in K} \alpha_t \hat{t}$ is measurable for every finite set K, and θ is measurable. **Q**

(b) For a less elementary measurable functional, consider the following construction. Let $\langle t_n\rangle_{n\in\mathbb{N}}$ be any sequence of distinct points in I. Then $\lim_{n\to\infty}\frac{1}{n}\#(\{i : i<n,\, t_i\in a\})=\frac{1}{2}$ for ν-almost every $a\subseteq I$. **P** Set $f_n(a)=1$ if $t_n\in a$, 0 otherwise. Then $\langle f_n\rangle_{n\in\mathbb{N}}$ is an independent sequence of random variables. By any of the versions of the Strong Law of Large Numbers in §273 (273D, 273H, 273I), $\lim_{n\to\infty}\frac{1}{n}\sum_{i=0}^{n-1}f_i=\frac{1}{2}$ a.e., which is what was claimed. **Q** So if we take any non-principal ultrafilter $\mathcal{F}$ on $\mathbb{N}$, and set $\theta a=\lim_{n\to\mathcal{F}}\frac{1}{n}\#(\{i : i<n,\, t_i\in a\})$ for $a\subseteq I$, θ will be constant ν-almost everywhere, and measurable; and it is easy to check that θ is additive. Note that $\theta\{t\}=0$ for every t, so $\theta\in M_\tau^\perp$, by 464Fb.

(c) If $\mathcal{F}$ is any non-principal ultrafilter on $\mathcal{I}$, and we set $\theta a=1$ for $a\in\mathcal{F}$, 0 otherwise, then θ is an additive functional which is purely non-measurable, by 464Ca.

For further remarks on where to look for measurable and purely non-measurable functionals, see 464P-464Q below.

464K The space $M_{\rm m}$: Lemma Let I be any set, ν the usual measure on $\mathcal{P}I$, and M the L-space of bounded additive functionals on $\mathcal{P}I$. Write $M_{\rm m}$ for the set of measurable $\theta\in M$, and $\Delta(\theta)=\overline{\int}\theta\,d\nu$ for $\theta\in M^+$, as in 464H.

(a) $|\theta|\in M_{\rm m}$ for every $\theta\in M_{\rm m}$.

(b) A functional $\theta\in M^+$ is measurable iff $\Delta(\theta)=\frac{1}{2}\theta I$.

(c) $M_{\rm m}$ is a solid linear subspace of M.

proof (a)(i) Take any $\theta\in M_{\rm m}\cap M_\tau^\perp$, where M_τ is the space of completely additive functionals on $\mathcal{P}I$.

(α) $\theta=_{\rm a.e.}\frac{1}{2}\theta I$. **P** For any $\alpha\in\mathbb{R}$, $A_\alpha=\{a : \theta a<\alpha\}$ is measurable; but also $b\in A$ whenever $a\in A$ and $a\triangle b$ is finite, by 464Fb, so νA must be either 1 or 0, by 464Ac. Setting $\delta=\sup\{\alpha : \nu A_\alpha=0\}$, we see that $\nu A_\delta=0$, $\nu A_{\delta+2^{-n}}=1$ for every $n\in\mathbb{N}$, so that $\theta=\delta$ a.e. Also, because $a\mapsto I\setminus a$ is a measure space automorphism, $\theta(I\setminus a)=\delta$ for almost every a, so there is some a such that $\theta a=\theta(I\setminus a)=\delta$, and $\delta=\frac{1}{2}\theta I$. **Q**

(β) For any $b\subseteq I$, $\theta(a\cap b)=\frac{1}{2}\theta b$ for almost every a. **P** We know that $\theta a=\frac{1}{2}\theta I$ for almost every a, by (α). But $a\mapsto a\triangle b:\mathcal{P}I\to\mathcal{P}I$ is inverse-measure-preserving, so $\theta(a\triangle b)=\frac{1}{2}\theta I$ for almost every a. This means that $\theta a=\theta(a\triangle b)$ for almost every a, and

$$\theta(a\cap b)=\frac{1}{2}(\theta b+\theta a-\theta(a\triangle b))=\frac{1}{2}\theta b$$

for almost every a. **Q**

(γ) θ^+, taken in M, is measurable. **P** For any $n\in\mathbb{N}$ we can find $b_n\subseteq I$ such that $\theta^-b_n+\theta^+(I\setminus b_n)\le 2^{-n}$, so that

$$|\theta^+a-\theta(a\cap b_n)|=|\theta^+a-\theta^+(a\cap b_n)+\theta^-(a\cap b_n)|\le\theta^+(I\setminus b_n)+\theta^-b_n\le 2^{-n}$$

for every $a\subseteq I$. But as $\theta(a\cap b_n)$ is constant a.e. for every n, by (β), so is θ^+, and θ^+ is measurable. **Q**

Consequently $|\theta|=2\theta^+-\theta$ is measurable.

(ii) Now take an arbitrary $\theta\in M_{\rm m}$. Because M is Dedekind complete (354N, 354Ee), $M=M_\tau+M_\tau^\perp$ (353I), and we can express θ as $\theta_1+\theta_2$ where $\theta_1\in M_\tau$ and $\theta_2\in M_\tau^\perp$; moreover, $|\theta|=|\theta_1|+|\theta_2|$ (352Fb). Now θ_1 is measurable, by 464Ja, so $\theta_2=\theta-\theta_1$ is measurable; as $\theta_2\in M_\tau^\perp$, (i-γ) tells us that $|\theta_2|$ is measurable. On the other hand, $|\theta_1|$ belongs to M_τ and is measurable, so $|\theta|=|\theta_1|+|\theta_2|$ is measurable.

Thus (a) is true.

(b) Let f be a ν-integrable function such that $\Delta(\theta)\le f$ a.e. and $\int f\,d\nu=\Delta(\theta)$. Then

$$\theta I-f(a)\le\theta I-\theta a=\theta(I\setminus a)$$

for almost every a, so

$$\theta I-\Delta(\theta)\le\underline{\int}\theta(I\setminus a)\nu(da)=\underline{\int}\theta(a)\nu(da)$$

because $a \mapsto I \setminus a$ is a measure space automorphism, as in the proof of 464Ha. So if $\Delta(\theta) = \frac{1}{2}\theta I$ then $\underline{\int}\theta\,d\nu = \overline{\int}\theta\,d\nu$ and θ is ν-integrable (133Jd), therefore (because ν is complete) $(\operatorname{dom}\nu)$-measurable. On the other hand, if θ is measurable, then

$$\Delta(\theta) = \int \theta\,d\nu = \int \theta(I \setminus a)\nu(da) = \theta I - \int \theta\,d\nu = \theta I - \Delta(\theta),$$

so surely $\Delta(\theta) = \frac{1}{2}\theta I$.

(c) Of course $M_{\rm m}$ is a linear subspace. If $\theta_0 \in M_{\rm m}$ and $|\theta| \leq |\theta_0|$, then $|\theta_0| \in M_{\rm m}$, by (a), so $\Delta(|\theta_0|) = \frac{1}{2}|\theta_0|(I)$, by (b). Because $\theta^+ \leq |\theta| \leq |\theta_0|$, $\Delta(\theta^+) = \frac{1}{2}\theta^+ I$ (464H(f-i)), and θ^+ is measurable, by (b) in the reverse direction. Similarly, θ^- is measurable, and $\theta = \theta^+ - \theta^-$ is measurable. As θ and θ_0 are arbitrary, $M_{\rm m}$ is solid.

464L The space $M_{\rm pnm}$: Lemma Let I be any set, ν the usual measure on $\mathcal{P}I$, and M the L-space of bounded additive functionals on $\mathcal{P}I$. This time, write $M_{\rm pnm}$ for the set of those members of M which are purely non-measurable in the sense of 464I.

(a) If $\theta \in M^+$, then θ is purely non-measurable iff $\Delta(\theta) = \theta I$.

(b) $M_{\rm pnm}$ is a solid linear subspace of M.

proof (a)(i) If θ is purely non-measurable, and $f \geq \theta$ is integrable, then $\{a : f(a) \geq \theta I\}$ is a measurable set including $\{a : \theta a = \theta I\}$, so has measure 1, and $\int f \geq \theta I$; as f is arbitrary, $\Delta(\theta) = \theta I$.

(ii) If $\Delta(\theta) = \theta I$, then $\Delta(\theta') = \theta' I$ whenever $0 \leq \theta' \leq \theta$, by 464Hf. But this means that θ' cannot be measurable whenever $0 < \theta' \leq \theta$, by 464Kc above, so that $\theta' \notin M_\tau$ whenever $0 < \theta' \leq \theta$, by 464Ja. Thus $\theta \in M_\tau^\perp$.

By 464Hc, $\nu^*\{a : \alpha \leq \theta a \leq \Delta(\theta)\} = 1$ for every $\alpha < \Delta(\theta)$. Let $\langle m(n)\rangle_{n\in\mathbb{N}}$ be a sequence in $\mathbb{N}$ such that $\prod_{n=0}^\infty 1 - 2^{-m(n)} = \frac{1}{2}$, and define X, λ and ϕ as in 464Ba. Set $\eta_n = 2^{-n}/m(n) > 0$ for each n. Consider the sets $A_n = \{a : \theta a \geq (1-\eta_n)\theta I\}$ for each $n \in \mathbb{N}$. Then $\nu^* A_n = 1$ for each n, and $\lambda^*(\prod_{n\in\mathbb{N}} A_n^{m(n)}) = 1$. Because ϕ is inverse-measure-preserving, $\nu^*(\phi[\prod_{n\in\mathbb{N}} A_n^{m(n)}]) = 1$ (413Eh). But if $\mathfrak{x} = \langle\langle a_{ni}\rangle_{i<m(n)}\rangle_{n\in\mathbb{N}}$ belongs to $\prod_{n\in\mathbb{N}} A_n^{m(n)}$, then

$$\theta(\textstyle\bigcap_{i<m(n)} a_{ni}) \geq \theta I - m(n)\eta_n\theta I = (1-2^{-n})\theta I$$

for each n, and

$$\theta(\phi(\mathfrak{x})) \geq \sup_{n\in\mathbb{N}} \theta(\textstyle\bigcap_{i<m(n)} a_{ni}) = \theta I.$$

Thus the filter $\{a : \theta a = \theta I\}$ includes $\phi[\prod_{n\in\mathbb{N}} A_n^{m(n)}]$ and has outer measure 1, so that θ is purely non-measurable.

(b)(i) If $\theta \in M_{\rm pnm}$ and $|\theta'| \leq |\theta|$, then $\Delta(|\theta|) = |\theta|(I)$, by the definition in 464I, so $\Delta(|\theta'|) = |\theta'|(I)$, by 464H(f-ii), and $\theta' \in M_{\rm pnm}$, by (a) above. Thus $M_{\rm pnm}$ is solid.

(ii) If θ_1, $\theta_2 \in M_{\rm pnm}$, then

$$\Delta(|\theta_1| + |\theta_2|) = \Delta(|\theta_1|) + \Delta(|\theta_2|) = |\theta_1|(I) + |\theta_2|(I) = (|\theta_1| + |\theta_2|)(I)$$

(using 464Hb), and $|\theta_1| + |\theta_2| \in M_{\rm pnm}$; as $|\theta_1 + \theta_2| \leq |\theta_1| + |\theta_2|$, $\theta_1 + \theta_2 \in M_{\rm pnm}$. Thus $M_{\rm pnm}$ is closed under addition.

(iii) It follows from (ii) that if $\theta \in M_{\rm pnm}$ then $n\theta \in M_{\rm pnm}$ for every integer $n \geq 1$, and then from (i) that $\alpha\theta \in M_{\rm pnm}$ for every $\alpha \in \mathbb{R}$; so that $M_{\rm pnm}$ is closed under scalar multiplication, and is a linear subspace.

464M Theorem (Fremlin & Talagrand 79) Let I be any set. Write M for the L-space of bounded finitely additive functionals on $\mathcal{P}I$, and $M_{\rm m}$, $M_{\rm pnm}$ for the spaces of measurable and purely non-measurable functionals, as in 464K-464L. Then $M_{\rm m}$ and $M_{\rm pnm}$ are complementary bands in M.

proof (a) We know from 464K and 464L that these are both solid linear subspaces of M. Next, $M_{\rm m} \cap M_{\rm pnm} = \{0\}$. **P** If θ belongs to the intersection, then $\Delta(|\theta|) = \frac{1}{2}|\theta|(I) = |\theta|(I)$, by 464Kb and 464La; so $\theta = 0$. **Q**

(b) Now recall that every element of M^+ is expressible in the form $\theta_1+\theta_2$ where $\theta_1 \in M_{\rm m}^+$ and $\theta_2 \in M_{\rm pnm}^+$; this is 464He, using 464Kb and 464La again. Because $M_{\rm m}$ and $M_{\rm pnm}$ are linear subspaces, with intersection $\{0\}$, $M = M_{\rm m} \oplus M_{\rm pnm}$. Now $M_{\rm pnm} \subseteq M_{\rm m}^\perp$, so $M_{\rm m} + M_{\rm m}^\perp = M$ and $M_{\rm m} = M_{\rm m}^{\perp\perp}$ is a complemented band (352R); similarly, $M_{\rm pnm}$ is a complemented band. Since $(M_{\rm m} + M_{\rm pnm})^\perp = \{0\}$, $M_{\rm m}$ and $M_{\rm pnm}$ are complementary bands (see 352S).

464N Corollary (FREMLIN & TALAGRAND 79) Let I be any set, and let μ be Talagrand's measure on $\mathcal{P}I$; write Σ for its domain. Then every bounded additive functional on $\mathcal{P}I$ is Σ-measurable.

proof Defining M, $M_{\rm m}$ and $M_{\rm pnm}$ as in 464K and 464L, we see that every functional in $M_{\rm m}$ is Σ-measurable because it is (by definition) $(\operatorname{dom}\nu)$-measurable, where ν is the usual measure on $\mathcal{P}I$. If $\theta \in M_{\rm pnm}^+$, then $\mathcal{F} = \{a : \theta a = \theta I\}$ is a non-measurable filter; but this means that $\mu\mathcal{F} = 1$, by the construction of μ, so that $\theta = \theta I$ μ-a.e. So if θ is any member of $M_{\rm pnm}$, both θ^+ and θ^- are Σ-measurable, and $\theta = \theta^+ - \theta^-$ also is.

464O Remark Note that we have a very simple description of the behaviour of additive functionals as seen by the measure μ. Since $M_\tau \subseteq M_{\rm m}$, we have a three-part band decomposition $M = M_\tau \oplus (M_{\rm m} \cap M_\tau^\perp) \oplus M_{\rm pnm}$.

(i) Functionals in M_τ are T-measurable, where T is the domain of ν, therefore Σ-measurable, just because they can be built up from the functionals $a \mapsto \chi a(t)$, as in 464Fb.

(ii) A functional in $M_{\rm m}$ is T-measurable, by definition; but a functional θ in $M_{\rm m} \cap M_\tau^\perp$ is actually constant, with value $\frac{1}{2}\theta I$, ν-almost everywhere. **P** For $\theta \geq 0$, this is 464Kb; the general case follows because $M_{\rm m} \cap M_\tau^\perp$ is solid in M. **Q** Thus the almost-constant nature of the functionals described in 464Jb is typical of measurable functionals in $M_\tau^\perp$.

(iii) Finally, a functional $\theta \in M_{\rm pnm}$ is equal to θI μ-almost everywhere; once again, this follows from the definition of 'purely non-measurable' and the construction of μ for $\theta \geq 0$, and from the fact that $M_{\rm pnm}$ is solid for other θ.

(iv) Thus we see that any $\theta \in M_\tau^\perp = (M_{\rm m} \cap M_\tau^\perp) \oplus M_{\rm pnm}$ is constant μ-a.e. We also have $\int \theta\,d\mu = \Delta(\theta)$ for every $\theta \geq 0$ (look at $\theta \in M_{\rm m}$ and $\theta \in M_{\rm pnm}$ separately, using 464La for the latter), so that if $h \in M^*$ is the linear functional of 464Hb, then $\int \theta\,d\mu = h(\theta)$ for every $\theta \in M$.

464P More on purely non-measurable functionals (a) We can discuss non-negative additive functionals on $\mathcal{P}I$ in terms of the Stone-Čech compactification βI of I, as follows. For any set $A \subseteq \beta I$ set $H_A = \{a : a \subseteq I,\ A \subseteq \widehat{a}\}$, where $\widehat{a} \subseteq \beta I$ is the open-and-closed set corresponding to $a \subseteq I$. If $A \neq \emptyset$, H_A is a filter on I. Write $\mathcal{A}$ for the family of those sets $A \subseteq \beta I$ such that $\nu^* H_A = 1$, where ν is the usual measure on $\mathcal{P}I$. Then $\mathcal{A}$ is a σ-ideal. **P** Of course $A \in \mathcal{A}$ whenever $A \subseteq B \in \mathcal{A}$, since then $H_A \supseteq H_B$. If $\langle A_n\rangle_{n\in\mathbb{N}}$ is a sequence in $\mathcal{A}$ with union A, then $\nu^*(\bigcap_{n\in\mathbb{N}} H_{A_n}) = 1$, by 464C; but $H_A \supseteq \bigcap_{n\in\mathbb{N}} H_{A_n}$. **Q** Note that if $A \in \mathcal{A}$ then $\overline{A} \in \mathcal{A}$, because $H_A = H_{\overline{A}}$. We see also that $\{z\} \in \mathcal{A}$ for every $z \in \beta I \setminus I$ (since $H_{\{z\}}$ is a non-principal ultrafilter, as in 464Jb), while $\{t\} \notin \mathcal{A}$ for any $t \in I$ (since $H_{\{t\}} = \{a : t \in a\}$ has measure $\frac{1}{2}$).

Because βI can be identified with the Stone space of $\mathcal{P}I$ (4A2I(b-i)), we have a one-to-one correspondence between non-negative additive functionals θ on $\mathcal{P}I$ and Radon measures μ_θ on βI, defined by writing $\mu_\theta(\widehat{a}) = \theta a$ whenever $a \subseteq I$ and $\theta \in M^+$ (416Qb). (This is not the same as the measure μ_θ of part (e) of the proof of 464H, which is on a much larger space.) Now suppose that θ is a non-negative additive functional on $\mathcal{P}I$. Then $\mathcal{F}_\theta = \{a : \theta a = \theta I\}$ is either $\mathcal{P}I$ or a filter on I. If we set $F_\theta = \bigcap\{\widehat{a} : a \in \mathcal{F}_\theta\}$, then $\mathcal{F}_\theta = H_{F_\theta}$ (4A2I(b-iii)). Since $a \in \mathcal{F}_\theta$ iff $\theta a = \theta I$,

$$\begin{aligned} F_\theta &= \bigcap\{\widehat{a} : a \in \mathcal{F}_\theta\} = \bigcap\{\widehat{a} : \theta a = \theta I\} \\ &= \bigcap\{\widehat{a} : \mu_\theta \widehat{a} = \mu_\theta(\beta I)\} = \beta I \setminus \bigcup\{\widehat{a} : \mu_\theta \widehat{a} = 0\}. \end{aligned}$$

But this is just the support of μ_θ (411Nd), because $\{\widehat{a} : a \subseteq I\}$ is a base for the topology of βI.

Thus we see that $\theta \in M^+$ is purely non-measurable iff the support F_θ of the measure μ_θ belongs to $\mathcal{A}$. If you like, θ is purely non-measurable iff the support of μ_θ is 'small'.

(b) Yet another corollary of 464C is the following. Since M is a set of real-valued functions on $\mathcal{P}I$, it has the corresponding topology $\mathfrak{T}_p$ of pointwise convergence as a subspace of $\mathbb{R}^{\mathcal{P}I}$. Now if $C \subseteq M_{\rm pnm}$

is countable, its $\mathfrak{T}_p$-closure $\overline{C}$ is included in $M_{\rm pnm}$. **P** It is enough to consider the case in which C is non-empty and $0 \notin C$. For each $\theta \in C$, $\mathcal{F}_{|\theta|} = \{a : |\theta|(a) = |\theta|(I)\}$ is a filter with outer measure 1, so $\mathcal{F} = \{a : |\theta|(a) = |\theta|(I) \text{ for every } \theta \in C\}$ also has outer measure 1, by 464Cb. Now suppose that $\theta_0 \in \overline{C}$. If $a \in \mathcal{F}$, then $|\theta|(I \setminus a) = 0$ for every $\theta \in C$, that is, $\theta b = 0$ whenever $\theta \in C$ and $b \subseteq I \setminus a$ (362Ba). But this means that $\theta_0 b = 0$ whenever $b \subseteq I \setminus a$, so $|\theta_0|(I \setminus a) = 0$ and $|\theta_0|(a) = |\theta_0|(I)$. Thus $\mathcal{F}_{|\theta_0|} \supseteq \mathcal{F}$, so has outer measure 1, and θ_0 is also purely non-measurable. **Q**

(c) If $\theta \in M$ is such that $\theta a = 0$ for every countable set $a \subseteq I$, then $\theta \in M_{\rm pnm}$. **P** ν is inner regular with respect to the family $\mathcal{W}$ of sets which are determined by coordinates in countable subsets of I, by 254Ob. But if $W \in \mathcal{W}$ and $\nu W > 0$, let $J \subseteq I$ be a countable set such that W is determined by coordinates in J; then $|\theta|(J) = 0$, so if a is any member of W we shall have $a \cup (I \setminus J) \in W \cap \mathcal{F}_{|\theta|}$. As W is arbitrary, $\nu^* \mathcal{F}_{|\theta|} = 1$ and θ is purely non-measurable. **Q**

In particular, if $\theta \in M_\sigma \cap M_\tau^\perp$, where M_σ is the space of countably additive functionals on $\mathcal{P}I$ (362B), then $\theta \in M_{\rm pnm}$. (For 'ordinary' sets I, $M_\sigma = M_\tau$; see 438Xa. But this observation is peripheral to the concerns of the present section.)

In the language of (a) above, we have a closed set in βI, being $F = \beta I \setminus \bigcup\{\widehat{a} : a \in [I]^{\leq\omega}\}$; and if θ is such that the support of μ_θ is included in F, then θ is purely non-measurable.

464Q More on measurable functionals (a) We know that $M_{\rm m}$ is a band in M, and that it includes the band M_τ. So it is natural to look at the band $M_{\rm m} \cap M_\tau^\perp$. I showed in part (a) of the proof of 464K that if $\theta \in M_{\rm m} \cap M_\tau^\perp$, and $b \subseteq I$, we have $\theta(a \cap b) = \frac{1}{2}\theta b$ for ν-almost every a.

(b) It follows that if θ is any non-zero non-negative functional in $M_{\rm m} \cap M_\tau^\perp$, we can find a family $\langle a_\xi \rangle_{\xi<\omega_1}$ in $\mathcal{P}I$ which is independent in the sense that $\theta(\bigcap_{\xi\in K} a_\xi) = 2^{-\#(K)}\theta I$ for every non-empty finite $K \subseteq I$. **P** Choose the a_ξ inductively, observing that at the inductive step we have to satisfy only countably many conditions of the form $\theta(a_\xi \cap b) = \frac{1}{2}\theta b$, where b runs over the subalgebra generated by $\{a_\eta : \eta < \xi\}$; so that ν-almost any a will serve for a_ξ. **Q**

In terms of the associated measure μ_θ on βI, this means that $\langle (\widehat{a}_\xi)^\bullet \rangle_{\xi<\omega_1}$ is an uncountable independent family in the measure algebra of μ_θ, and μ_θ has Maharam type at least ω_1.

Turning this round, we see that if λ is a Radon measure on βI, of countable Maharam type, and $\lambda I = 0$, then the corresponding functional on $\mathcal{P}I$ is purely non-measurable.

[For a stronger result in this direction, see §531 in Volume 5.]

(c) Another striking property of measurable additive functionals is the following. If $\theta \in M_{\rm m} \cap M_\tau^\perp$, and $n \in \mathbb{N}$, then $\theta(a_0 \cap a_1 \cap \ldots \cap a_n) = 2^{-n-1}\theta I$ for ν^{n+1}-almost every $a_0, \ldots, a_n \subseteq I$, where ν^{n+1} is the product measure on $(\mathcal{P}I)^{n+1}$. **P** For $K \subseteq \{0, \ldots, n\}$ write $\psi_K(a_0, \ldots, a_n) = I \cap \bigcap_{i\in K} a_i \setminus \bigcup_{i\leq n, i\notin K} a_i$ for $a_0, \ldots, a_n \subseteq I$; for $\mathcal{S} \subseteq \mathcal{P}\{0, \ldots, n\}$ write $\phi_{\mathcal{S}}(\mathfrak{x}) = \bigcup_{K\in\mathcal{S}} \psi_K(\mathfrak{x})$ for $\mathfrak{x} \in (\mathcal{P}I)^{n+1}$. Then, for any $t \in I$,

$$\nu^{n+1}\{\mathfrak{x} : t \in \phi_{\mathcal{S}}(\mathfrak{x})\} = \sum_{K\in\mathcal{S}} \nu^{n+1}\{\mathfrak{x} : t \in \phi_K(\mathfrak{x})\} = 2^{-n-1}\#(\mathcal{S}).$$

Moreover, for different t, these sets are independent. So if $\#(\mathcal{S}) = 2^n$, that is, if $\mathcal{S}$ is just half of $\mathcal{P}\{0, \ldots, n\}$, then $\phi_{\mathcal{S}}$ will be inverse-measure-preserving, by the arguments in 464B. (In fact 464Bb is the special case $n = 2$, $\mathcal{S} = \{K : \#(K) \geq 2\}$.)

Accordingly we shall have $\theta(\phi_{\mathcal{S}}(\mathfrak{x})) = \frac{1}{2}\theta I$ for almost every $\mathfrak{x}$ whenever $\mathcal{S} \subseteq \mathcal{P}\{0, \ldots, n\}$ has 2^n members. Since there are only finitely many sets $\mathcal{S}$, the set E is ν^{n+1}-conegligible, where

$$E = \{\mathfrak{x} : \mathfrak{x} \in (\mathcal{P}I)^{n+1}, \theta(\phi_{\mathcal{S}}(\mathfrak{x})) = \frac{1}{2}\theta I \text{ whenever } \mathcal{S} \subseteq \mathcal{P}\{0, \ldots, n\} \text{ and } \#(\mathcal{S}) = 2^n\}.$$

But given $\mathfrak{x} = (a_0, \ldots, a_n) \in E$, let $K_1, \ldots, K_{2^{n+1}}$ be a listing of $\mathcal{P}\{0, \ldots, n\}$ in such an order that $\theta(\psi_{K_i}(\mathfrak{x})) \leq \theta(\psi_{K_j}(\mathfrak{x}))$ whenever $i \leq j$, and consider $\mathcal{S} = \{K_1, \ldots, K_{2^n}\}$; since

$$\sum_{i=1}^{2^n} \theta(\psi_{K_i}(\mathfrak{x})) = \theta(\phi_{\mathcal{S}}(\mathfrak{x})) = \frac{1}{2}\theta I = \frac{1}{2}\sum_{i=0}^{2^{n+1}} \theta(\psi_{K_i}(\mathfrak{x})),$$

we must have $\theta(\psi_{K_i}(\mathfrak{x})) = 2^{-n-1}\theta I$ for every i. In particular, $\theta(\psi_{\{0,\ldots,n\}}(\mathfrak{x})) = 2^{-n-1}\theta I$, that is, $\theta(\bigcap_{i\leq n} a_i) = 2^{-n-1}\theta I$. As this is true whenever $a_0, \ldots, a_n \in E$, we have the result. **Q**

464R A note on $\ell^\infty(I)$ As already noted in 464F, we have, for any set I, a natural additive map $\chi : \mathcal{P}I \to \ell^\infty(I) \cong L^\infty(\mathcal{P}I)$, giving rise to an isomorphism between the L-space M of bounded additive functionals on $\mathcal{P}I$ and $\ell^\infty(I)^*$. If we write $\tilde{\mu}$ for the image measure $\mu\chi^{-1}$ on $\ell^\infty(I)$, where μ is Talagrand's measure on $\mathcal{P}I$, and $\tilde{\Sigma}$ for the domain of $\tilde{\mu}$, then every member of $\ell^\infty(I)^*$ is $\tilde{\Sigma}$-measurable, by 464N. Thus $\tilde{\Sigma}$ includes the cylindrical σ-algebra of $\ell^\infty(I)$ (4A3T). We also have a band decomposition $\ell^\infty(I)^* = \ell^\infty(I)^*_{\rm m} \oplus \ell^\infty(I)^*_{\rm pnm}$ corresponding to the decomposition $M = M_{\rm m} \oplus M_{\rm pnm}$.

In this context, M_τ corresponds to $\ell^\infty(I)^\times$ (363K). Since we can identify $\ell^\infty(I)$ with $\ell^1(I)^* = \ell^1(I)^\times$ (243Xl), and $\ell^1(I)$, like any L-space, is perfect, $\ell^\infty(I)^\times$ is the canonical image of $\ell^1(I)$ in $\ell^\infty(I)^*$. Because any functional in $M_\tau^\perp$ is μ-almost constant (464O), any functional in $(\ell^\infty(I)^\times)^\perp$ will be $\tilde{\mu}$-almost constant.

464X Basic exercises (a) Let I be any set and λ a Radon measure on βI. Show that if the support of λ is a separable subset of $\beta I \setminus I$, then the corresponding additive functional on $\mathcal{P}I$ is purely non-measurable.

(b) Let I be any set, and $\tilde{\mu}$ the image of Talagrand's measure on $\ell^\infty(I)$, as in 464R. Show that $\tilde{\mu}$ has a barycenter in $\ell^\infty(I)$ iff I is finite.

464Y Further exercises (a) Show that there is a sequence $\langle \mathcal{F}_n \rangle_{n\in\mathbb{N}}$ of distinct non-principal ultrafilters on $\mathbb{N}$ with the following property: if we define $h(a) = \{n : a \in \mathcal{F}_n\}$ for $a \subseteq \mathbb{N}$, then $\{h(a) : a \subseteq \mathbb{N}\}$ is ν-negligible.

(b) Let μ be Talagrand's measure on $\mathcal{P}\mathbb{N}$, and let λ be the corresponding product measure on $X = \mathcal{P}\mathbb{N} \times \mathcal{P}\mathbb{N}$. Define $\Phi : X \to \ell^\infty$ by setting $\Phi(a,b) = \chi a - \chi b$ for all $a, b \subseteq \mathbb{N}$. Show that Φ is Pettis integrable (463Ya) with indefinite Pettis integral Θ defined by setting $(\Theta E)(n) = \int_E f_n d\lambda$, where $f_n(a,b) = \chi a(n) - \chi b(n)$. Show that $K = \{h\Phi : h \in \ell^{\infty *}, \|h\| \leq 1\}$ contains every f_n, and in particular is not $\mathfrak{T}_m$-compact, so the identity map from $(K, \mathfrak{T}_p)$ to $(K, \mathfrak{T}_m)$ is not continuous.

464Z Problem Let I be an infinite set, and $\tilde{\mu}$ the image in $\ell^\infty(I)$ of Talagrand's measure on $\mathcal{P}I$ (464R). Is $\tilde{\mu}$ a topological measure for the weak topology of $\ell^\infty(I)$?

464 Notes and comments The central idea of this section appears in 464B: the algebraic structure of $\mathcal{P}I$ leads to a variety of inverse-measure-preserving functions ϕ from powers $(\mathcal{P}I)^K$ to $\mathcal{P}I$. The simplest of these is the measure space automorphism $a \mapsto I \setminus a$, as used in the proofs of 464Ca, 464Hf, 464Ka and 464Kb. Then we have the map $(a,b,c) \mapsto (a \cap b) \cup (a \cap c) \cup (b \cap c)$, as in 464Bb, and the generalization of this in the argument of 464Qc; and, most important of all, the map $\langle \langle a_{ni} \rangle_{i<m(n)} \rangle_{n\in\mathbb{N}} \mapsto \bigcup_{n\in\mathbb{N}} \bigcap_{i<m(n)} a_{ni}$ of 464Ba. In each case we can use probabilistic intuitions to guide us to appropriate formulae, since the events $t \in \phi(\mathfrak{x})$ are always independent, so if they have probability $\frac{1}{2}$ for every $t \in I$, the function ϕ will be inverse-measure-preserving. Of course this depends on the analysis of product measures in §254. It means also that we must use the 'ordinary' product measure defined there; but happily this coincides with the 'Radon' product measure of §417 (416U).

Talagrand devised his measure when seeking an example of a pointwise compact set of measurable functions which is not compact for the topology of convergence in measure, as in 464E. The remarkable fact that it is already, in effect, a measure on the cylindrical σ-algebra of ℓ^∞ (464R) became apparent later, and requires a much more detailed analysis. An alternative argument not explicitly involving the Riesz space structure of the space M of bounded additive functionals may be found in Fremlin & Talagrand 79. The proof I give here depends on the surprising fact that, for non-negative additive functionals, the upper integral $\overline{\int} d\nu$ is additive (464Hb), even though the functionals may be very far from being measurable. Once we know this, we can apply the theory of Banach lattices to investigate the corresponding linear functional on the L-space M. There is a further key step in 464Hd. We there have a non-negative $\theta \in M_\tau^\perp$ such that $\theta I = 1$ and $\beta\theta' I \leq \overline{\int} \theta' d\nu \leq \gamma\theta' I$ whenever $0 \leq \theta' \leq \theta$. It is easy to deduce that $\{a : \alpha\nu b \leq \theta(a \cap b) \leq \gamma\theta b$ for every $b \in K\}$ has outer measure 1 for every finite $K \subseteq \mathcal{P}I$ and $\alpha < \beta$. If α and γ are very close, this means that there will be many families (a,b,c) in $\mathcal{P}I$ which, as measured by θ, look like independent sets of measure γ, so that $\theta((a\cap b)\cup(a\cap c)\cup(b\cap c)) \eqsim 3\gamma^2 - 2\gamma^3$. But since we must also have $\theta((a\cap b)\cup(a\cap c)\cup(b\cap c)) \leq \gamma$ almost everywhere, we can get information about the possible values of γ.

Once having noted this remarkable dichotomy between 'measurable' and 'purely non-measurable' functionals, it is natural to look for other ways in which they differ. The position seems to be that 'simple' Radon measures on $\beta I \setminus I$ (e.g., all measures with separable support (464Xa) or countable Maharam type (464Qb)) have to correspond to purely non-measurable functionals. Of course the simplest possible measures on βI are those concentrated on I, which give rise to functionals which belong to M_τ and are therefore measurable; it is functionals in $M_{\rm m} \cap M_\tau^\perp$ which have to give rise to 'complicated' Radon measures.

The fact that every element of $M_\tau^\perp$ is almost constant for Talagrand's measure leads to an interesting Pettis integrable function (464Yb). The suggestion that Talagrand's measure on ℓ^∞ might be a topological measure for the weak topology (464Z) is a bold one, but no more outrageous than the suggestion that it might measure every continuous linear functional once seemed. Talagrand's measure does of course measure every Baire set for the weak topology (4A3U). I note here that the usual measure on $\{0,1\}^I$, when transferred to $\ell^\infty(I)$, is actually a Radon measure for the weak* topology $\mathfrak{T}_s(\ell^\infty, \ell^1)$, because on $\{0,1\}^I$ this is just the ordinary topology.

465 Stable sets

The structure of general pointwise compact sets of measurable functions is complex and elusive. One particular class of such sets, however, is relatively easy to describe, and has a variety of remarkable properties, some of them relevant to important questions arising in the theory of empirical measures. In this section I outline the theory of 'stable' sets of measurable functions from Talagrand 84 and Talagrand 87.

The first steps are straightforward enough. The definition of stable set (465B) is not obvious, but given this the basic properties of stable sets listed in 465C are natural and easy to check, and we come quickly to the fact that (for complete locally determined spaces) pointwise bounded stable sets are relatively pointwise compact sets of measurable functions (465D). A less transparent, but still fairly elementary, argument leads to the next reason for looking at stable sets: the topology of pointwise convervence on a stable set is finer than the topology of convergence in measure (465G).

At this point we come to a remarkable fact: a uniformly bounded set A of functions on a complete probability space is stable if and only if certain laws of large numbers apply 'nearly uniformly' on A. These laws are expressed in conditions (ii), (iv) and (v) of 465M. For singleton sets A, they can be thought of as versions of the strong law of large numbers described in §273. To get the full strength of 465M a further idea in this direction needs to be added, described in 465H here.

The theory of stable sets applies in the first place to sets of true functions. There is however a corresponding notion applicable in function spaces, which I explore briefly in 465O-465R. Finally, I mention the idea of 'R-stable' set (465S-465U), obtained by using τ-additive product measures instead of c.l.d. product measures in the definition.

465A Notation Throughout this section, I will use the following notation.

(a) If X is a set and Σ a σ-algebra of subsets of X, I will write $\mathcal{L}^0(\Sigma)$ for the space of Σ-measurable functions from X to $\mathbb{R}$, as in §463.

(b) I will identify $\mathbb{N}$ with the set of finite ordinals, so that each $n \in \mathbb{N}$ is the set of its predecessors, and a power X^n becomes identified with the set of functions from $\{0, \dots, n-1\}$ to X.

(c) If (X, Σ, μ) is any measure space, then for finite sets I (in particular, if $I = k \in \mathbb{N}$) I write μ^I for the c.l.d. product measure on X^I, as defined in 251W. (For definiteness, let us take μ^0 to be the unique probability measure on $X^0 = \{\emptyset\}$.) If (X, Σ, μ) is a probability space, then for any set I μ^I is to be the product probability measure on X^I, as defined in §254.

(d) We shall have occasion to look at free powers of algebras of sets. If X is a set and Σ is an algebra of subsets of X, then for any set I write $\bigotimes_I \Sigma$ for the algebra of subsets of X^I generated by sets of the form $\{w : w(i) \in E\}$ where $i \in I$ and $E \in \Sigma$, and $\widehat{\bigotimes}_I \Sigma$ for the σ-algebra generated by $\bigotimes_I \Sigma$.

(e) Now for a new idea, which will be used in almost every paragraph of the section. If X is a set, $A \subseteq \mathbb{R}^X$ a set of real-valued functions defined on X, $E \subseteq X$, $\alpha < \beta$ in $\mathbb{R}$ and $k \geq 1$, write

$$D_k(A,E,\alpha,\beta) = \bigcup_{f\in A}\{w : w\in E^{2k}, f(w(2i))\le\alpha, \\ f(w(2i+1))\ge\beta \text{ for } i<k\}.$$

We are now ready for the main definition.

465B Definition Let (X,Σ,μ) be a semi-finite measure space. Following TALAGRAND 84, I say that a set $A\subseteq\mathbb{R}^X$ is **stable** if whenever $E\in\Sigma$, $0<\mu E<\infty$ and $\alpha<\beta$ in $\mathbb{R}$, there is some $k\ge 1$ such that $(\mu^{2k})^*D_k(A,E,\alpha,\beta)<(\mu E)^{2k}$.

Remark I hope that the next few results will show why this concept is important. It is worth noting at once that these sets D_k need not be measurable, and that some of the power of the definition derives precisely from the fact that quite naturally arising sets A can give rise to non-measurable sets $D_k(A,E,\alpha,\beta)$. If, however, the set A is countable, then all the corresponding D_k will be measurable; this will be important in the results following 465R.

465C I start with a list of the 'easy' properties of stable sets, derivable more or less directly from the definition.

Proposition Let (X,Σ,μ) be a semi-finite measure space.

(a) If $A\subseteq\mathbb{R}^X$ is stable, then any subset of A is stable.

(b) If $A\subseteq\mathbb{R}^X$ is stable, then $\overline{A}$, the closure of A in $\mathbb{R}^X$ for the topology of pointwise convergence, is stable.

(c) Suppose that $A\subseteq\mathbb{R}^X$, $E\in\Sigma$, $n\ge 1$ and $\alpha<\beta$ are such that $0<\mu E<\infty$ and $(\mu^{2n})^*D_n(A,E,\alpha,\beta)<(\mu E)^{2n}$. Then

$$\frac{1}{(\mu E)^{2k}}(\mu^{2k})^*D_k(A,E,\alpha,\beta)\to 0$$

as $k\to\infty$.

(d) If A, $B\subseteq\mathbb{R}^X$ are stable, then $A\cup B$ is stable.

(e) If $A\subseteq\mathbb{R}^X$ is stable, then $\gamma A=\{\gamma f : f\in A\}$ is stable, for any $\gamma\in\mathbb{R}$.

(f) If $A\subseteq\mathbb{R}^X$ is stable and $g\in\mathcal{L}^0=\mathcal{L}^0(\Sigma)$, then $A+g=\{f+g : f\in A\}$ is stable.

(g) If $A\subseteq\mathcal{L}^0$ is finite it is stable.

(h) If $A\subseteq\mathbb{R}^X$ is stable so is $\{|f| : f\in A\}$.

(i) If $A\subseteq\mathbb{R}^X$ is stable and $g\in\mathcal{L}^0$, then $A\times g=\{f\times g : f\in A\}$ is stable.

(j) If $\hat{\mu}$, $\tilde{\mu}$ are the completion and c.l.d. version of μ, then $A\subseteq\mathbb{R}^X$ is stable with respect to one of the measures μ, $\hat{\mu}$, $\tilde{\mu}$ iff it is stable with respect to the others.

(k) Let ν be an indefinite-integral measure over μ (§234). If $A\subseteq\mathbb{R}^X$ is stable with respect to μ, it is stable with respect to ν and with respect to $\nu\restriction\Sigma$.

(l) Let $h:\mathbb{R}\to\mathbb{R}$ be a continuous non-decreasing function. If $A\subseteq\mathbb{R}^X$ is stable, so is $\{hf : f\in A\}$.

(m) In particular, if $A\subseteq\mathbb{R}^X$ is stable, so is $\{f^+ : f\in A\}$.

proof (a) This is immediate from the definition in 465B, since $D_k(B,E,\alpha,\beta)\subseteq D_k(A,E,\alpha,\beta)$ for all k, E, α and β.

(b) Given E such that $0<\mu E<\infty$, and $\alpha<\beta$, take α', β' such that $\alpha<\alpha'<\beta'<\beta$. Then it is easy to see that $D_k(\overline{A},E,\alpha,\beta)\subseteq D_k(A,E,\alpha',\beta')$, so

$$(\mu^{2k})^*D_k(\overline{A},E,\alpha,\beta)\le(\mu^{2k})^*D_k(A,E,\alpha',\beta')<(\mu E)^{2k}$$

for some $k\ge 1$. As E, α and β are arbitrary, $\overline{A}$ is stable.

(c) For any $m\ge 1$ and $l<n$, if we identify $X^{2(mn+l)}$ with $(X^{2n})^m\times X^{2l}$, we see that $D_{mn+l}(A,E,\alpha,\beta)$ becomes identified with a subset of $D_n(A,E,\alpha,\beta)^m\times E^{2l}$. (If $w\in D_{mn+l}(A,E,\alpha,\beta)$, there is an $f\in A$ such that $f(w(2i))\le\alpha$, $f(w(2i+1))\ge\beta$ for $i<mn+l$. Now $(w(2rn),w(2rn+1),\dots,w(2rn+2n-1))\in D_n(A,E,\alpha,\beta)$ for $r<m$.) So

$$\begin{aligned}\tfrac{1}{(\mu E)^{2(mn+l)}}(\mu^{2(mn+l)})^*D_{mn+l}(A,E,\alpha,\beta)&\\ \leq \tfrac{1}{(\mu E)^{2(mn+l)}}\big((\mu^{2n})^*D_n(A,E,\alpha,\beta)\big)^m(\mu E)^{2l}&\\ = \big(\tfrac{1}{(\mu E)^{2n}}(\mu^{2n})^*D_n(A,E,\alpha,\beta)\big)^m \to 0&\end{aligned} \tag{251Wm}$$

as $m \to \infty$.

(d) Note that $D_k(A \cup B, E, \alpha, \beta) = D_k(A, E, \alpha, \beta) \cup D_k(B, E, \alpha, \beta)$ for all E, k, α and β. Now, given that $0 < \mu E < \infty$ and $\alpha < \beta$, there are m, $n \geq 1$ such that $(\mu^{2m})^*D_m(A, E, \alpha, \beta) < (\mu E)^{2m}$ and $(\mu^{2n})^*D_n(A, E, \alpha, \beta) < (\mu E)^{2n}$. So, by (c) above,

$$\begin{aligned}\tfrac{1}{(\mu E)^{2k}}(\mu^{2k})^*D_k(A \cup B, E, \alpha, \beta)&\\ \leq \tfrac{1}{(\mu E)^{2k}}\big((\mu^{2k})^*D_k(A, E, \alpha, \beta) + (\mu^{2k})^*D_k(B, E, \alpha, \beta)\big) \to 0&\end{aligned}$$

as $k \to \infty$, and there is some k such that $(\mu^{2k})^*D_k(A \cup B, E, \alpha, \beta) < (\mu E)^{2k}$. As E, α and β are arbitrary, $A \cup B$ is stable.

(e)(i) If $\gamma > 0$, $D_k(\gamma A, E, \alpha, \beta) = D_k(A, E, \alpha/\gamma, \beta/\gamma)$ for all k, E, α and β, so the result is elementary. Similarly, if $\gamma = 0$, then $D_k(\gamma A, E, \alpha, \beta) = \emptyset$ whenever $k \geq 1$, $E \in \Sigma$ and $\alpha < \beta$, so again we see that γA is stable.

(ii) If $\gamma = -1$ then, for any k, E, α and β,

$$\begin{aligned}D_k(-A, E, \alpha, \beta) &= \bigcup_{f \in A}\{w : w \in E^{2k},\ f(w(2i)) \geq -\alpha,\\ &\qquad f(w(2i+1)) \leq -\beta\ \forall\ i < k\}\\ &= \phi[D_k(A, E, -\beta, -\alpha)],\end{aligned}$$

where $\phi : X^{2k} \to X^{2k}$ is the measure space automorphism defined by setting

$$\phi(w) = (w(1), w(0), w(3), w(2), \dots, w(2k-1), w(2k-2))$$

for $w \in X^{2k}$. So, given $E \in \Sigma$ and $\alpha < \beta$, there is a $k \geq 1$ such that

$$(\mu^{2k})^*D_k(-A, E, \alpha, \beta) = (\mu^{2k})^*D_k(A, E, -\beta, -\alpha) < (\mu E)^{2k}.$$

So $-A$ is stable.

(iii) Together with (i) this shows that γA is stable for every $\gamma \in \mathbb{R}$.

(f) Take E such that $0 < \mu E < \infty$, and $\alpha < \beta$. Set $\eta = \frac{1}{2}(\beta - \alpha) > 0$. Then there is a $\gamma \in \mathbb{R}$ such that $F = \{x : x \in E, \gamma \leq g(x) \leq \gamma + \eta\}$ has non-zero measure. Set $\alpha' = \alpha - \gamma$, $\beta' = \beta - \gamma - \eta$. Then $D_k(A + g, F, \alpha, \beta) \subseteq D_k(A, F, \alpha', \beta')$, while $\alpha' < \beta'$. So if we take $k \geq 1$ such that $(\mu^{2k})^*D_k(A, F, \alpha', \beta') < (\mu F)^{2k}$, then

$$(\mu^{2k})^*D_k(A + g, E, \alpha, \beta) \leq (\mu^{2k})^*D_k(A + g, F, \alpha, \beta) + \mu^{2k}(E^{2k} \setminus F^{2k}) < (\mu E)^{2k}.$$

(g) If A is empty, or contains only the constant function $\mathbf{0}$ with value 0, this is trivial. Now (f) tells us that $\{g\} = \{\mathbf{0}\} + g$ is stable for every $g \in \mathcal{L}^0$, and from (d) it follows that any finite subset of $\mathcal{L}^0$ is stable.

(h) Writing $|A|$ for $\{|f| : f \in A\}$, then

$$D_k(|A|, E, \alpha, \beta) \subseteq D_k(A, E, \alpha, \beta) \cup D_k(-A, E, \alpha, \beta) = D_k(A \cup (-A), E, \alpha, \beta)$$

whenever $0 \leq \alpha < \beta$. So (d) and (e) tell us that in this case there is some k such that $D_k(|A|, E, \alpha, \beta)$ has outer measure less than $(\mu E)^{2k}$.

(i) Let $E \in \Sigma$, $\alpha < \beta$ be such that $0 < \mu E < \infty$. Set

$$E_0 = \{x : x \in E,\, g(x) = 0\}, \quad E_1 = \{x : x \in E,\, g(x) > 0\},$$

$$E_2 = \{x : x \in E,\, g(x) < 0\}.$$

(i) Suppose that $\mu E_0 > 0$. Then $D_1(A \times g, E, \alpha, \beta)$ does not meet E_0, so $\mu^* D_1(A \times g, E, \alpha, \beta) < \mu E$.

(ii) Suppose that $\mu E_1 > 0$. Let $\eta > 0$ be such that

$$\max(\alpha, \tfrac{\alpha}{1+\eta}) = \alpha' < \beta' = \min(\beta, \tfrac{\beta}{1+\eta}).$$

Let $\gamma > 0$ be such that $\mu F > 0$, where $F = \{x : x \in E,\, \gamma \leq g(x) \leq \gamma(1+\eta)\}$. If $x \in F$ then

$$f(x)g(x) \leq \alpha \implies f(x) \leq \frac{\alpha}{g(x)} \leq \frac{\alpha'}{\gamma},$$

$$f(x)g(x) \geq \beta \implies f(x) \geq \frac{\beta}{g(x)} \geq \frac{\beta'}{\gamma}.$$

So

$$D_k(A \times g, F, \alpha, \beta) \subseteq D_k(A, F, \frac{\alpha'}{\gamma}, \frac{\beta'}{\gamma})$$

for every k. Now, because A is stable, there is some $k \geq 1$ such that

$$(\mu^{2k})^* D_k(A, F, \frac{\alpha'}{\gamma}, \frac{\beta'}{\gamma}) < (\mu F)^{2k},$$

and in this case $(\mu^{2k})^* D_k(A \times g, E, \alpha, \beta) < (\mu E)^{2k}$, just as in the argument for (f) above.

(iii) If $\mu E_2 > 0$, then we know from (e) that $-A$ is stable, so (ii) tells us that there is a $k \geq 1$ such that $(\mu^{2k})^* D_k((-A) \times (-g), E, \alpha, \beta) < (\mu E)^{2k}$.

Since one of these three cases must occur, and since E, α and β are arbitrary, $A \times g$ is stable.

(j) The product measures μ^{2k}, $\hat{\mu}^{2k}$ and $\tilde{\mu}^{2k}$ are all the same (251Wn), so this follows immediately from the definition in 465B.

(k) Let h be a Radon-Nikodým derivative of ν with respect to μ (234B). Suppose that $0 < \nu E < \infty$ and $\alpha < \beta$. Then there is an $F \in \Sigma$ such that $F \subseteq E \cap \operatorname{dom} h$, $h(x) > 0$ for every $x \in F$, and $0 < \mu F < \infty$. There is a $k \geq 1$ such that $(\mu^{2k})^* D_k(A, F, \alpha, \beta) < (\mu F)^{2k}$, that is, there is a $W \subseteq F^{2k} \setminus D_k(A, F, \alpha, \beta)$ such that $\mu^{2k} W > 0$. In this case, $\nu^{2k} W > 0$. **P** Set $\tilde{h}(w) = \prod_{i=0}^{2k-1} h(w(i))$ for $w \in (\operatorname{dom} h)^{2k}$. Then ν^{2k} is the indefinite integral of $\tilde{h}$ with respect to μ^{2k} (253I), and $\tilde{h}(w) > 0$ for every $w \in F^{2k}$. **Q** Since $W \subseteq E^{2k} \setminus D_k(A, E, \alpha, \beta)$, $(\nu^{2k})^* D_k(A, E, \alpha, \beta) < (\nu E)^{2k}$; as E, α and β are arbitrary, A is stable with respect to ν.

Since ν is the completion of its restriction $\nu{\restriction}\Sigma$ (234Db), A is also stable with respect to $\nu{\restriction}\Sigma$, by (j).

(l) Write $B = \{hf : f \in A\}$. Suppose that $0 < \mu E < \infty$ and $\alpha < \beta$. If either $\alpha < h(\gamma)$ for every $\gamma \in \mathbb{R}$ or $h(\gamma) < \beta$ for every $\gamma \in \mathbb{R}$,

$$\mu^* D_1(B, E, \alpha, \beta) = \mu\emptyset = 0 < \mu E.$$

Otherwise, because h is continuous, the Intermediate Value Theorem tells us that there are $\alpha' < \beta'$ such that $\alpha < h(\alpha') < h(\beta') < \beta$. In this case $D_k(B, E, \alpha, \beta) \subseteq D_k(A, E, \alpha', \beta')$ for every k. Because A is stable, there is some $k \geq 1$ such that $(\mu^{2k})^* D_k(A, E, \alpha', \beta') < (\mu E)^{2k}$, so that $(\mu^{2k})^* D_k(B, E, \alpha, \beta) < (\mu E)^{2k}$. As E, α and β are arbitrary, B is stable.

(m) follows at once.

465D Now for the first result connecting the notion of 'stable' set with the concerns of this chapter.

Proposition Let (X,Σ,μ) be a complete locally determined measure space, and $A\subseteq\mathbb{R}^X$ a stable set.

(a) $A\subseteq\mathcal{L}^0=\mathcal{L}^0(\Sigma)$ (that is, every member of A is Σ-measurable).

(b) If $\{f(x):f\in A\}$ is bounded for each $x\in X$, then A is relatively compact in $\mathcal{L}^0$ for the topology of pointwise convergence.

proof (a) **?** Suppose, if possible, that there is a non-measurable $f\in A$. Then there is an $\alpha\in\mathbb{R}$ such that $D_0=\{x:f(x)>\alpha\}\notin\Sigma$. Because μ is locally determined, there is an $F_0\in\Sigma$ such that $\mu F_0<\infty$ and $D_0\cap F_0\notin\Sigma$. Let $F_1\subseteq F_0$ be a measurable envelope of $D_0\cap F_0$ (132Ee). Then $D_0\cap F_1=D_0\cap F_0$ is not measurable; because μ is complete, $F_1\setminus D_0$ cannot be negligible. Now $D_0=\bigcup_{n\in\mathbb{N}}\{x:f(x)\geq\alpha+2^{-n}\}$, so there is some $\beta>\alpha$ such that $D_1=F_1\cap\{x:f(x)\geq\beta\}$ is not negligible. Let E be a measurable envelope of D_1. Then, setting $P=\{x:x\in E,\,f(x)\leq\alpha\}$, $Q=\{x:x\in E,\,f(x)\geq\beta\}$ we have $\mu^*P=\mu^*Q=\mu E>0$.

Now suppose that $k\geq 1$. Then $D_k(\{f\},E,\alpha,\beta)\supseteq(P\times Q)^k$, so

$$(\mu^{2k})^*D_k(\{f\},E,\alpha,\beta)=(\mu^*P\cdot\mu^*Q)^k=(\mu E)^{2k}$$

(251Wm again). Since this is true for every k, $\{f\}$ is not stable, and (by 465Ca) A cannot be stable; which contradicts our hypothesis. **X**

(b) Because $\{f(x):x\in A\}$ is bounded for each x, $\overline{A}$, the closure of A in $\mathbb{R}^X$, is compact for the topology of pointwise convergence. But $\overline{A}$ is stable, by 465Cb, so is included in $\mathcal{L}^0$, by (a).

465E The topology $\mathfrak{T}_s(\mathcal{L}^2,\mathcal{L}^2)$ Some of the arguments below will rely on ideas of compactness in function spaces. There are of course many ways of expressing the method, but a reasonably accessible one uses the Hilbert space L^2, as follows. Let (X,Σ,μ) be any measure space. Then $L^2=L^2(\mu)$ is a Hilbert space with a corresponding weak topology $\mathfrak{T}_s(L^2,L^2)$ defined by the functionals $u\mapsto(u|v)$ for $v\in L^2$. In the present section it will be more convenient to regard this as a topology $\mathfrak{T}_s(\mathcal{L}^2,\mathcal{L}^2)$ on the space $\mathcal{L}^2=\mathcal{L}^2(\mu)$ of square-integrable real-valued functions, defined by the functionals $f\mapsto\int f\times g$ for $g\in\mathcal{L}^2$. The essential fact we need is that norm-bounded sets are relatively weakly compact. In L^2, this is because Hilbert spaces are reflexive (4A4Ka). In $\mathcal{L}^2$, given an ultrafilter $\mathcal{F}$ containing a $\|\,\|_2$-bounded set $B\subseteq\mathcal{L}^2$, $v=\lim_{f\to\mathcal{F}}f^\bullet$ must be defined in L^2 for $\mathfrak{T}_s(L^2,L^2)$, and now there is a $g\in\mathcal{L}^2$ such that $g^\bullet=v$; in which case

$$\lim_{f\to\mathcal{F}}\int f\times h=\lim_{f\to\mathcal{F}}(f^\bullet|h^\bullet)=(g^\bullet|h^\bullet)=\int g\times h$$

for every $h\in\mathcal{L}^2$. Note that we are free to take g to be a Σ-measurable function with domain X (241Bk).

465F Lemma Let (X,Σ,μ) be a measure space, and $B\subseteq\mathcal{L}^2=\mathcal{L}^2(\mu)$ a $\|\,\|_2$-bounded set. Suppose that $h\in\mathcal{L}^2$ belongs to the closure of B for $\mathfrak{T}_s(\mathcal{L}^2,\mathcal{L}^2)$. Then for any $\delta>0$, $k\geq 1$ the set

$$W=\bigcup_{f\in B}\{w:w\in X^k,w(i)\in\operatorname{dom}f\cap\operatorname{dom}h \text{ and } f(w(i))\geq h(w(i))-\delta \text{ for every } i<k\}$$

is μ^k-conegligible in X^k.

proof (a) Since completing the measure μ does not change the space $\mathcal{L}^2$ (244Xa) nor the product measure μ^k (251Wn), we may suppose that μ is complete.

(b) The first substantive fact to note is that there is a sequence $\langle f_n\rangle_{n\in\mathbb{N}}$ in B converging to h for $\mathfrak{T}_s=\mathfrak{T}_s(\mathcal{L}^2,\mathcal{L}^2)$. **P** Setting $C=\{f^\bullet:f\in B\}$, C is a bounded set in $L^2=L^2(\mu)$ and $h^\bullet$ belongs to the $\mathfrak{T}_s(L^2,L^2)$-closure of C. But L^2, being a normed space, is angelic in its weak topology (462D), and C is relatively compact in L^2, so there is a sequence in C converging to $h^\bullet$. We can represent this sequence as $\langle f_n^\bullet\rangle_{n\in\mathbb{N}}$ where $f_n\in B$ for every n, and now $\langle f_n\rangle_{n\in\mathbb{N}}\to h$ for $\mathfrak{T}_s$. **Q**

(c) The second component of the proof is the following simple idea. Suppose that $\langle E_n\rangle_{n\in\mathbb{N}}$ is a sequence in Σ such that $\bigcap_{n\in I}E_n$ is negligible for every infinite set $I\subseteq\mathbb{N}$. For $m\geq 1$, $I\subseteq\mathbb{N}$ set

$$V_m(I)=\textstyle\bigcap_{n\in I}\{w:w\in X^m,\,\exists\,i<m,\,w(i)\in E_n\}.$$

Then $\mu^mV_m(I)=0$ for every infinite $I\subseteq\mathbb{N}$. **P** Induce on m. For $m=1$ this is just the original hypothesis on $\langle E_n\rangle_{n\in\mathbb{N}}$. For the inductive step to $m+1$, identify μ^{m+1} with the product of μ^m and μ, and observe that

$$V_{m+1}(I)^{-1}[\{x\}] = \{w : (w,x) \in V_{m+1}(I)\} = V_m(\{n : n \in I,\ x \notin E_n\})$$

for every $x \in X$. Now, setting $I_x = \{n : n \in I,\ x \notin E_n\}$, $F = \{x : I_x \text{ is finite}\}$, we have

$$F = \bigcup_{r\in\mathbb{N}} \bigcap_{n\in I\setminus r} E_n,$$

so F is negligible, while if $x \notin F$ then $V_m(I_x)$ is negligible, by the inductive hypothesis. But this means that almost every horizontal section of $V_{m+1}(I)$ is negligible, and $V_{m+1}(I)$, being measurable, must be negligible, by Fubini's theorem (252F). Thus the induction proceeds. **Q**

(d) Now let us return to the main line of the argument from (b). For each $n \in \mathbb{N}$, set $E_n = \{x : x \in \operatorname{dom} f_n \cap \operatorname{dom} h,\ f_n(x) < h(x) - \delta\}$. If $I \subseteq \mathbb{N}$ is infinite, then $\bigcap_{n\in I} E_n$ is negligible. **P** Setting $G = \bigcap_{n\in I} E_n$, μG is finite (because $\delta\chi E_n \leq |h - f_n|$ a.e., so $\mu E_n < \infty$ for every n) and $\int_G f_n \leq \int_G h - \delta\mu G$ for every $n \in I$. But $\lim_{n\to\infty} \int_G f_n = \int_G h$ and I is infinite, so

$$\delta\mu G \leq \inf_{n\in I} |\textstyle\int_G h - \int_G f_n| = 0. \ \mathbf{Q}$$

By (c), it follows that

$$V = \bigcap_{n\in\mathbb{N}} \{w : w \in X^k,\ \exists\, i < k,\ w(i) \in E_n\}$$

is negligible. But if we set $Y = \bigcap_{n\in\mathbb{N}} \operatorname{dom} f_n \cap \operatorname{dom} h$, Y is a conegligible subset of X, Y^k is a conegligible subset of X^k, and $Y^k \setminus V \subseteq W$, so W is conegligible, as required.

465G Theorem Let (X, Σ, μ) be a semi-finite measure space, and $A \subseteq \mathcal{L}^0 = \mathcal{L}^0(\Sigma)$ a stable set of measurable functions. Let $\mathfrak{T}_p$ and $\mathfrak{T}_m$ be the topologies of pointwise convergence and convergence in measure, as in §463. Then the identity map from A to itself is $(\mathfrak{T}_p, \mathfrak{T}_m)$-continuous.

proof ? Suppose, if possible, otherwise.

(a) We must have an $f_0 \in A$, a set $F \in \Sigma$ of finite measure, and an $\epsilon > 0$ such that for every $\mathfrak{T}_p$-neighbourhood U of f_0 there is an $f \in A \cap U$ such that $\int_F \min(1, |f - f_0|)d\mu \geq \epsilon$. Set

$$B = \{\min(\chi F, |f - f_0|) : f \in A\}.$$

Then

$$B = \{\chi F - (\chi F - |f - f_0|)^+ : f \in A\}$$

is stable, by 465Cf, 465Ch, 465Cm and 465Ce, used repeatedly. Setting $B' = \{f : f \in B,\ \int f \geq \epsilon\}$, B' is again stable (465Ca). Our hypothesis is that f_0 is in the $\mathfrak{T}_p$-closure of $A' = \{f : f \in A,\ \int \min(\chi F, |f - f_0|) \geq \epsilon\}$; since $f \mapsto \min(\chi F, |f - f_0|)$ is $\mathfrak{T}_p$-continuous, 0 belongs to the $\mathfrak{T}_p$-closure of the image of A' under this map, which is B'.

(b) Let $\mathcal{F}$ be an ultrafilter on B' which $\mathfrak{T}_p$-converges to 0. Because B' is $\|\ \|_2$-bounded (since $0 \leq f \leq \chi F$ for every $f \in B'$), $\mathcal{F}$ also has a $\mathfrak{T}_s(\mathcal{L}^2, \mathcal{L}^2)$-limit h say, as noted in 465E; and we can suppose that h is measurable and defined everywhere. We must have

$$\textstyle\int_F h = \lim_{f\to\mathcal{F}} \int_F f \geq \epsilon > 0.$$

So there is a $\delta > 0$ such that $E = \{x : x \in F,\ h(x) \geq 3\delta\}$ has measure greater than 0.

(c) Because B' is stable, there must be some $k \geq 1$ such that $(\mu^{2k})^* D_k(B', E, \delta, 2\delta) < (\mu E)^{2k}$. Let $W \subseteq E^{2k} \setminus D_k(B', E, \delta, 2\delta)$ be a measurable set of positive measure. By Fubini's theorem, there must be $x_0, \ldots, x_{k-1}$ such that $\mu^k V$ is defined and greater than 0, where

$$V = \{v : v \in X^k,\ (x_0, v(0), x_1, v(1), \ldots, x_{k-1}, v(k-1)) \in W\}.$$

Set $C = \{f : f \in B',\ f(x_i) \leq \delta \text{ for every } i < k\}$; then $C \in \mathcal{F}$, because $\mathcal{F} \to 0$ for $\mathfrak{T}_p$. Accordingly h belongs to the $\mathfrak{T}_s(\mathcal{L}^2, \mathcal{L}^2)$-closure of C. But now 465F tells us that there must be a $v \in V$ and an $f \in C$ such that $f(v(i)) \geq h(v(i)) - \delta$ for every $i < k$.

Consider $w = (x_0, v(0), \ldots, x_{k-1}, v(k-1))$. We know that $w \in W$ (because $v \in V$), so, in particular, $w \in E^{2k}$ and $h(w(i)) \geq 3\delta$ for every $i < 2k$; accordingly

$$f(w(2i+1)) = f(v(i)) \geq h(v(i)) - \delta \geq 2\delta$$

for every $i < k$. On the other hand, $f(w(2i)) = f(x_i) \leq \delta$ for every $i < k$, because $f \in C$. But this means that f witnesses that $w \in D_k(B', E, \delta, 2\delta)$, which is supposed to be disjoint from W. **X**

This contradiction shows that the theorem is true.

465H We shall need some interesting and important general facts concerning powers of measures. I start with an important elaboration of the strong law of large numbers.

Theorem Let (X, Σ, μ) be any probability space. For $n \in \mathbb{N}$, write Λ_n for the domain of the product measure μ^n. For $w \in X^{\mathbb{N}}$, $k \geq 1$, $n \geq 1$ write ν_{wk} for the probability measure with domain $\mathcal{P}X$ defined by writing

$$\nu_{wk}(E) = \frac{1}{k}\#(\{i : i < k,\, w(i) \in E\})$$

for $E \subseteq X$, and ν_{wk}^n for the corresponding product measure on X^n.

Then whenever $n \geq 1$ and $f : X^n \to \mathbb{R}$ is bounded and Λ_n-measurable, $\lim_{k\to\infty} \int f d\nu_{wk}^n$ exists, and is equal to $\int f d\mu^n$, for $\mu^{\mathbb{N}}$-almost every $w \in X^{\mathbb{N}}$.

proof (a) For $k \geq n$ and $w \in X^{\mathbb{N}}$, set

$$h_k(w) = \tfrac{(k-n)!}{k!} \textstyle\sum_{\pi : n \to k \text{ is injective}} f(w\pi).$$

Setting $M = \sup_{v \in X^n} |f(v)|$, we have

$$\begin{aligned} |h_k(w) - \int f d\nu_{wk}^n| &= |\tfrac{(k-n)!}{k!} \sum_{\pi : n \to k \text{ is injective}} f(w\pi) - \tfrac{1}{k^n} \sum_{\pi : n \to k} f(w\pi)| \\ &\leq M\big(\tfrac{(k-n)!}{k!} - \tfrac{1}{k^n}\big) + \tfrac{M}{k^n}\big(k^n - \tfrac{k!}{(k-n)!}\big) \to 0 \end{aligned}$$

as $k \to \infty$, for every $w \in X^{\mathbb{N}}$.

(b) Write Λ for the domain of $\mu^{\mathbb{N}}$, and for $k \geq n$ set

$$\mathrm{T}_k = \{W : W \in \Lambda,\, w\pi \in W \text{ whenever } w \in W \text{ and } \pi \in S_k\},$$

where S_k is the set of bijections $\psi : \mathbb{N} \to \mathbb{N}$ such that $\psi(i) = i$ for $i \geq k$. Then $\langle \mathrm{T}_k \rangle_{k \geq n}$ is a non-increasing sequence of σ-subalgebras of Λ. For any injective function $\pi : n \to k$ there are just $(k-n)!$ extensions of π to a member of S_k. So

$$h_k(w) = \tfrac{1}{k!} \textstyle\sum_{\pi \in S_k} f(w\pi\restriction n)$$

for every w. Observe that $h_k(w\psi) = h_k(w)$ for every $\psi \in S_k$, $w \in X^{\mathbb{N}}$, so h_k is T_k-measurable. (Of course we need to look back at the definition of h_k to confirm that it is Λ-measurable.)

(c) For any $k \geq n$, h_k is a conditional expectation of h_n on T_k. **P** If $W \in \mathrm{T}_k$, then

$$\textstyle\int_W h_k(w)dw = \frac{1}{k!}\sum_{\pi \in S_k} \int_W f(w\pi\restriction n)dw = \frac{1}{k!}\sum_{\pi \in S_k} \int_W g(w\pi)dw$$

where $g(w) = f(w\restriction n)$ for $w \in X^{\mathbb{N}}$. Now observe that for every $\pi \in S_k$ the map $w \mapsto w\pi$ is a measure space automorphism of $X^{\mathbb{N}}$ which leaves W unchanged, because $W \in \mathrm{T}_k$; so that $\int_W g(w\pi)dw = \int_W g(w)dw$, by 235Ic. So $\int_W h_k = \int_W g$. But (since $W \in \mathrm{T}_k \subseteq \mathrm{T}_n$) $\int_W h_n$ is also equal to $\int_W g$, and $\int_W h_k = \int_W h_n$. As W is arbitrary, h_k is a conditional expectation of h_n on T_k. **Q**

(d) By the reverse martingale theorem (275K), $h_\infty(w) = \lim_{k\to\infty} h_k(w)$ is defined for almost every $w \in X^{\mathbb{N}}$. Accordingly $\lim_{k\to\infty} \int f d\nu_{wk}^n$ is defined for almost every w.

(e) To see that the limit is $\int f d\mu^n$, observe that if $W \in \mathrm{T}_\infty = \bigcap_{k\in\mathbb{N}} \mathrm{T}_k$ then $\mu^{\mathbb{N}}W$ must be either 0 or 1. **P** Set $\gamma = \mu^{\mathbb{N}}W$. Let $\epsilon > 0$. Then there is a $V \in \bigotimes_{\mathbb{N}} \Sigma$ (notation: 465Ad) such that $\mu^{\mathbb{N}}(W \triangle V) \leq \epsilon$ (254Fe). There is some k such that V is determined by coordinates in k. If we set $\pi(i) = 2k - i$ for $i < 2k$, i for $i \geq 2k$, then $V' = \{w\pi : w \in V\}$ is determined by coordinates in $2k \setminus k$, so $\mu^{\mathbb{N}}(V \cap V') = (\mu^{\mathbb{N}}V)^2$.

On the other hand, because $W \in \mathrm{T}_{2k}$, the measure space automorphism $w \mapsto w\pi$ does not move W, and $\mu^{\mathbb{N}}(W \setminus V') = \mu^{\mathbb{N}}(W \setminus V)$. Accordingly

$$\gamma = \mu^{\mathbb{N}}(W \cap W) \leq \mu^{\mathbb{N}}(V \cap V') + 2\mu^{\mathbb{N}}(W \setminus V) \leq (\mu^{\mathbb{N}}V)^2 + 2\epsilon \leq (\gamma + \epsilon)^2 + 2\epsilon.$$

As ϵ is arbitrary, $\gamma \leq \gamma^2$ and $\gamma \in \{0, 1\}$. **Q**

(e) Now 275K tells us that h_∞ is T_∞-measurable, therefore essentially constant, and must be equal to its expectation almost everywhere. But, setting $W = X^{\mathbb{N}}$ in (c), we see that $\int h_k = \int f(w\restriction n)dw = \int f d\mu^n$ for every k, so

$$\lim_{k\to\infty} \int f d\nu^n_{wk} = h_\infty(w) = \int f d\mu^n$$

for almost every w, as claimed.

465I Now for a string of lemmas, working towards the portmanteau Theorem 465M. The first is elementary.

Lemma Let X be a set, and Σ a σ-algebra of subsets of X. For $w \in X^{\mathbb{N}}$, $k \geq 1$, $n \geq 1$ write ν_{wk} for the probability measure with domain $\mathcal{P}X$ defined by writing

$$\nu_{wk}(E) = \frac{1}{k}\#(\{i : i < k,\, w(i) \in E\})$$

for $E \subseteq X$. Then for any $k \in \mathbb{N}$ and any set I, $w \mapsto \nu^I_{wk}(W)$ is $\widehat{\bigotimes}_{\mathbb{N}}\Sigma$-measurable (notation: 465Ad) for every $W \in \widehat{\bigotimes}_I \Sigma$.

proof Write $\mathcal{W}$ for the set of subsets W of X^I such that $w \mapsto \nu^I_{wk}(W)$ is $\widehat{\bigotimes}_{\mathbb{N}}\Sigma$-measurable. Then $X^I \in \mathcal{W}$, $W' \setminus W \in \mathcal{W}$ whenever $W, W' \in \mathcal{W}$ and $W \subseteq W'$, and $\bigcup_{n\in\mathbb{N}} W_n \in \mathcal{W}$ whenever $\langle W_n\rangle_{n\in\mathbb{N}}$ is a non-decreasing sequence in $\mathcal{W}$. Write $\mathcal{V}$ for the set of Σ-cylinders in X^I, that is, sets expressible in the form $\{v : v(i) \in E_i \text{ for every } i \in J\}$, where $J \subseteq I$ is finite and $E_i \in \Sigma$ for $i \in J$. Then $\mathcal{V} \subseteq \mathcal{W}$. **P** If $J \subseteq I$ is finite and $E_i \in \Sigma$ for $i \in J$, then

$$w \mapsto \nu_{wk}E_i = \frac{1}{k}\sum_{j=0}^{k-1} \chi E_i(w(j))$$

is $\widehat{\bigotimes}_{\mathbb{N}}$-measurable for every $i \in J$. So

$$w \mapsto \nu^I_{wk}\{v : v(i) \in E_i \;\forall\, i \in J\} = \prod_{i\in J} \nu_{wk}E_i$$

is also measurable. **Q**

Because $V \cap V' \in \mathcal{V}$ for all V, $V' \in \mathcal{V}$, the Monotone Class Theorem (136B) tells us that $\mathcal{W}$ must include the σ-algebra generated by $\mathcal{V}$, which is $\widehat{\bigotimes}_I \Sigma$.

465J The next three lemmas are specifically adapted to the study of stable sets of functions.

Lemma Let (X, Σ, μ) be a probability space. For any $n \in \mathbb{N}$, $W \subseteq X^n$ I say that W is **symmetric** if $w\pi \in W$ whenever $w \in W$ and $\pi : n \to n$ is a bijection. Give each power X^n its product measure μ^n.

(a) Suppose that for each $n \geq 1$ we have a measurable set $W_n \subseteq X^n$, and that $W_{m+n} \subseteq W_m \times W_n$ for all m, $n \geq 1$, identifying X^{m+n} with $X^m \times X^n$. Then $\lim_{n\to\infty}(\mu^n W_n)^{1/n}$ is defined and equal to $\delta = \inf_{n\geq 1}(\mu^n W_n)^{1/n}$.

(b) Now suppose that each W_n is symmetric. Then there is an $E \in \Sigma$ such that $\mu E = \delta$ and $E^n \setminus W_n$ is negligible for every $n \in \mathbb{N}$.

(c) Next, let $\langle D_n\rangle_{n\geq 1}$ be a sequence of sets such that

$D_n \subseteq X^n$ is symmetric for every $n \geq 1$,

whenever $1 \leq m \leq n$, $v \in D_n$ then $v\restriction m \in D_m$.

Then $\delta = \lim_{n\to\infty}((\mu^n)^* D_n)^{1/n}$ is defined and there is an $E \in \Sigma$ such that $\mu E = \delta$ and $(\mu^n)^*(D_n \cap E^n) = (\mu E)^n$ for every $n \in \mathbb{N}$.

proof (a) For any $\eta > 0$, there is an $m \geq 1$ such that $\mu^m W_m \leq (\delta + \eta)^m$. If $n = mk + i$, where $k \geq 1$ and $i < m$, then (identifying X^n with $(X^m)^k \times X^i$) $W_n \subseteq (W_m)^k \times X^i$, so

$$\mu^n W_n \leq (\delta+\eta)^{mk} \leq \gamma(\delta+\eta)^{mk+i},$$

where

$$\gamma = \max_{i<m}(\tfrac{1}{\delta+\eta})^i.$$

So

$$\limsup_{n\to\infty}(\mu^n W_n)^{1/n} \leq (\delta+\eta)\limsup_{n\to\infty}\gamma^{1/n} = \delta+\eta.$$

As η is arbitrary,

$$\delta \leq \liminf_{n\to\infty}(\mu^n W_n)^{1/n} \leq \limsup_{n\to\infty}(\mu^n W_n)^{1/n} \leq \delta,$$

and $\lim_{n\to\infty}(\mu^n W_n)^{1/n} = \delta$.

(b) It is enough to consider the case $\delta > 0$.

(i) Consider the family $\mathbb{V}$ of sequences $\langle V_n\rangle_{n\geq 1}$ such that
for each $n \geq 1$, V_n is a symmetric measurable subset of X^n and $\mu^n V_n \geq \delta^n$,
if $1 \leq m \leq n$ then $v\restriction m \in V_m$ for every $v \in V_n$.

Observe that $\boldsymbol{W} = \langle W_n\rangle_{n\geq 1} \in \mathbb{V}$. Order $\mathbb{V}$ by saying that $\langle V_n\rangle_{n\geq 1} \leq \langle V'_n\rangle_{n\geq 1}$ if $V_n \subseteq V'_n$ for every n. For $\boldsymbol{V} = \langle V_n\rangle_{n\geq 1}$ in $\mathbb{V}$, set $\theta(\boldsymbol{V}) = \sum_{n=1}^{\infty} 2^{-n}\mu^n V_n$. Any non-increasing sequence $\langle\langle V_{kn}\rangle_{n\geq 1}\rangle_{k\in\mathbb{N}}$ in $\mathbb{V}$ has a lower bound $\langle\bigcap_{k\in\mathbb{N}} V_{kn}\rangle_{n\geq 1}$ in $\mathbb{V}$, so there must be a $\boldsymbol{W}' = \langle W'_n\rangle_{n\geq 1} \in \mathbb{V}$ such that $\boldsymbol{W}' \leq \boldsymbol{W}$ and $\theta(\boldsymbol{V}) = \theta(\boldsymbol{W}')$ whenever $\boldsymbol{V} \in \mathbb{V}$ and $\boldsymbol{V} \leq \boldsymbol{W}'$; that is, whenever $\langle V_n\rangle_{n\geq 1} \in \mathbb{V}$ and $V_n \subseteq W'_n$ for every $n \geq 1$, then $\mu^n V_n = \mu^n W'_n$ for every n.

(ii) For $x \in X$, $n \geq 1$ set $V_n^{(x)} = \{w : (x,w) \in W'_{n+1}\}$. Then $V_n^{(x)}$ is measurable for almost every x; let $X_1 \subseteq X$ be a conegligible set such that $V_n^{(x)}$ is measurable for every $x \in X_1$ and every $n \geq 1$. Every $V_n^{(x)}$ is symmetric, and if $1 \leq m \leq n$ and $v \in V_n^{(x)}$ then $v\restriction m \in V_m^{(x)}$. It follows that if m, $n \geq 1$ then $V_{m+n}^{(x)}$ becomes identified with a subset of $V_m^{(x)} \times V_n^{(x)}$.

From (a) we see that $\delta_x = \lim_{n\to\infty}(\mu^n V_n^{(x)})^{1/n}$ is defined for every $x \in X_1$. The map $x \mapsto \mu^n V_n^{(x)} : X_1 \to [0,\infty[$ is measurable for each n, by Fubini's theorem (252D), so $x \mapsto \delta_x$ is also measurable. Since $V_n^{(x)} \subseteq W'_n \subseteq W_n$ for every x and n, $\delta_x \leq \delta$ for every $x \in X_1$.

(iii) Set $E = \{x : x \in X_1, \delta_x = \delta\}$. Then $\mu E \geq \delta$. **P?** Otherwise, there is some $\beta < \delta$ such that $\mu F < \beta$, where $F = \{x : x \in X_1, \delta_x \geq \beta\}$. Now

$$\begin{aligned} X_1 \setminus F &= \{x : x \in X_1, \lim_{n\to\infty}(\mu^n V_n^{(x)})^{1/n} < \beta\} \\ &\subseteq \bigcup_{m\in\mathbb{N}}\bigcap_{n\geq m}\{x : x \in X_1, \mu^n V_n^{(x)} \leq \beta^n\}, \end{aligned}$$

so there is some $m \in \mathbb{N}$ such that $\mu H \geq 1-\beta$, where

$$H = \textstyle\bigcap_{n\geq m}\{x : x \in X_1, \mu^n V_n^{(x)} \leq \beta^n\}.$$

Set $\gamma_n = \mu^n W'_n \geq \delta^n$ for each n. Then, for any $n \geq m$,

$$\begin{aligned} \gamma_{n+1} = \mu^{n+1} W'_{n+1} &= \int_{X_1} \mu^n V_n^{(x)}\mu(dx) \\ &= \int_H \mu^n V_n^{(x)}\mu(dx) + \int_{X_1\setminus H} \mu^n V_n^{(x)}\mu(dx) \leq \beta^n + \beta\gamma_n \end{aligned}$$

because $V_n^{(x)} \subseteq W'_n$ for every x, and $\mu(X_1 \setminus H) \leq \beta$. An easy induction shows that $\gamma_{m+k} \leq k\beta^{m+k-1} + \beta^k\gamma_m$ for every $k \in \mathbb{N}$. But this means that

$$\delta^k = \delta^{-m}\delta^{m+k} \leq \delta^{-m}\gamma_{m+k} \leq \beta^k\delta^{-m}(k\beta^{m-1} + \gamma_m)$$

for every k; setting $\eta = (\delta-\beta)/\beta > 0$,

$$\tfrac{k(k-1)}{2}\eta \leq (1+\eta)^k = \big(\tfrac{\delta}{\beta}\big)^k \leq \delta^{-m}(k\beta^{m-1} + \gamma_m)$$

for every k, which is impossible. **XQ**

(iv) Next, for any $x \in E$, $\boldsymbol{V}^{(x)} = \langle V_n^{(x)} \rangle_{n\geq 1} \in \mathbb{V}$ and $\boldsymbol{V}^{(x)} \leq \boldsymbol{W}'$, so $\mu^n(W_n' \setminus V_n^{(x)}) = 0$ for every $n \geq 1$. This means that, given $n \geq 1$, every vertical section of $(E \times W_n') \setminus W_{n+1}'$ (regarded as a subset of $X \times X^n$) is negligible; so $(E \times W_n') \setminus W_{n+1}'$ is negligible. We are assuming that $\delta > 0$, so

$$E \subseteq \{x : x \in X_1, V_1^{(x)} \neq \emptyset\} \subseteq \{x : \{w : (x,w) \in W_2'\} \neq \emptyset\} \subseteq W_1'.$$

Now a simple induction shows that $E^n \setminus W_n'$ is negligible for every $n \geq 1$, so that $E^n \setminus W_n$ is negligible for every n, and we have an appropriate E. (Of course $\mu E = \delta$ exactly, because $(\mu E)^n \leq \mu W_n$ for every n.)

(c) For each $n \in \mathbb{N}$ let V_n be a measurable envelope of D_n in X^n. Define $\langle W_n \rangle_{n\geq 1}$ inductively by saying

$$W_1 = V_1,$$

$$W_{n+1} = \{w : w \in X^{n+1}, w\pi\restriction n \in W_n, \\ w\pi \in V_{n+1} \text{ for every bijection } \pi : n+1 \to n+1\}$$

for each $n \geq 1$. Then an easy induction on n shows that W_n is measurable and symmetric and that $D_n \subseteq W_n \subseteq V_n$, so that W_n is a measurable envelope of D_n and $\mu^n W_n = (\mu^n)^* D_n$.

Now $\langle W_n \rangle_{n\geq 1}$ satisfies the hypotheses of (b), so

$$\delta = \lim_{n\to\infty} (\mu^n W_n)^{1/n} = \lim_{n\to\infty} ((\mu^n)^* D_n)^{1/n}$$

is defined and there is a set $E \in \Sigma$, of measure δ, such that $E^n \setminus W_n$ is negligible for every n; but this means that

$$(\mu^n)^*(E^n \cap D_n) = \mu^n(E^n \cap W_n) = \delta^n$$

for every n, as required.

465K Lemma Let (X, Σ, μ) be a complete probability space, and $A \subseteq [0,1]^X$ a stable set. Suppose that $\epsilon > 0$ is such that $\int f d\mu \leq \epsilon^2$ for every $f \in A$. Then there are an $n \geq 1$ and a $W \in \widehat{\bigotimes}_n \Sigma$ (notation: 465Ad) and a $\gamma > \mu^n W$ such that $\int f d\nu \leq 3\epsilon$ whenever $f \in A$ and ν is a probability measure on X with domain including Σ such that $\nu^n W \leq \gamma$.

proof (a) For $n \in \mathbb{N}$ write $\tilde{C}_n = \bigcup_{f\in A} \{x : f(x) \geq \epsilon\}^n$. Then $\langle \tilde{C}_n \rangle_{n\in\mathbb{N}}$ satisfies the conditions of 465Jc, so $\delta = \lim_{n\to\infty} ((\mu^n)^* \tilde{C}_n)^{1/n}$ is defined, and there is an $E \in \Sigma$ such that $\mu E = \delta$ and $(\mu^n)^*(E^n \cap \tilde{C}_n) = \delta^n$ for every $n \in \mathbb{N}$. Now, for $B \subseteq [0,1]^X$ and $n \in \mathbb{N}$, write $C_n(B) = \bigcup_{f\in B} \{x : x \in E, f(x) \geq \epsilon\}^n$, so that $C_n(A) = E^n \cap \tilde{C}_n$, and $(\mu^n)^* C_n(A) = \delta^n$ for every n. For any $B \subseteq [0,1]^X$, $\langle C_n(B) \rangle_{n\in\mathbb{N}}$ also satisfies the conditions of 465Jc, and $\delta_B = \lim_{n\to\infty} ((\mu^n)^* C_n(B))^{1/n}$ is defined; we have $\delta_A = \delta$.

(b) If B, $B' \subseteq [0,1]^X$, then

$$(\mu^n)^* C_n(B) \leq (\mu^n)^* C_n(B \cup B') \leq (\mu^n)^* C_n(B) + (\mu^n)^* C_n(B')$$

for every n, so $\delta_B \leq \delta_{B\cup B'} \leq \max(\delta_B, \delta_{B'})$. It follows that if

$$\mathcal{G} = \{G : G \subseteq [0,1]^X \text{ is } \mathfrak{T}_p\text{-open}, \delta_{G\cap A} < \delta\},$$

where $\mathfrak{T}_p$ is the usual topology of $[0,1]^X$, no finite subfamily of $\mathcal{G}$ can cover A. Accordingly, since the $\mathfrak{T}_p$-closure $\overline{A}$ of A is $\mathfrak{T}_p$-compact, there is an $h \in \overline{A}$ such that $\delta_{G\cap A} = \delta$ for every $\mathfrak{T}_p$-open set G containing h.

(c) At this point recall that every function in $\overline{A}$ is measurable (465Cb, 465Da) and that $\int : \overline{A} \to [0,1]$ is $\mathfrak{T}_p$-continuous (465G). So $\int h \leq \epsilon^2$ and $\mu\{x : h(x) \geq \epsilon\} \leq \epsilon$.

? Suppose, if possible, that $\delta > \epsilon$. Then there is some $\eta > 0$ such that $\mu F > 0$, where $F = \{x : x \in E, h(x) < \epsilon - \eta\}$. For $k \in \mathbb{N}$, $u \in F^k$ set $G_u = \{f : f \in [0,1]^X, f(u(i)) < \epsilon - \eta \text{ for every } i < k\}$. Then G_u is an open neighbourhood of h, so $\delta_{G_u\cap A} = \delta$ and $(\mu^k)^*(C_k(G_u \cap A)) \geq \delta^k$. But because $F \subseteq E$ and $C_k(G_u \cap A) \subseteq E^k$, this means that $(\mu^k)^*(F^k \cap C_k(G_u \cap A)) = (\mu F)^k$.

For u, $v \in X^k$ write $u\#v$ for $(u(0), v(0), u(1), v(1), \dots, u(k-1), v(k-1)) \in X^{2k}$. Then

$$C_k(G_u \cap A) \cap F^k \subseteq \{v : u\#v \in D_k(A, F, \epsilon - \eta, \epsilon)\}$$

for any $u \in F^k$. So $(\mu^k)^*\{v : u\#v \in D_k(A, F, \epsilon - \eta, \epsilon)\} = (\mu F)^k$ for every $u \in F^k$. But this means that $(\mu^{2k})^* D_k(A, F, \epsilon - \eta, \epsilon) = (\mu F)^{2k}$. Since this is so for every $k \geq 1$, A is not stable. **X**

(d) Thus $\delta \leq \epsilon$. There is therefore some $n \geq 1$ such that $(\mu^n)^*\tilde{C}_n < (2\epsilon)^n$. Let $W \in \widehat{\bigotimes}_n \Sigma$ be a measurable envelope of $\tilde{C}_n$, and try $\gamma = (2\epsilon)^n$. If ν is any probability measure on X with domain including Σ such that $\nu^n W \leq \gamma$, then for any $f \in A$ we have

$$\{x : f(x) \geq \epsilon\}^n \subseteq \tilde{C}_n \subseteq W, \quad (\nu\{x : f(x) \geq \epsilon\})^n \leq \nu^n W \leq (2\epsilon)^n,$$

so that $\nu\{x : f(x) \geq \epsilon\} \leq 2\epsilon$. As $0 \leq f(x) \leq 1$ for every $x \in X$, $\int f d\nu \leq 3\epsilon$, as required.

465L Lemma (Talagrand 87) Let (X, Σ, μ) be a complete probability space, and $A \subseteq [0,1]^X$ a set which is not stable. Then there are measurable functions h_0, $h_1 : X \to [0,1]$ such that $\int h_0 \, d\mu < \int h_1 \, d\mu$ and $(\mu^{2k})^* \tilde{D}_k = 1$ for every $k \geq 1$, where

$$\tilde{D}_k = \bigcup_{f \in A} \{w : w \in X^{2k}, f(w(2i)) \leq h_0(w(2i)), \\ f(w(2i+1)) \geq h_1(w(2i+1)) \text{ for every } i < k\}. \qquad (*)$$

proof The proof divides into two cases.

case 1 Suppose that there is an ultrafilter $\mathcal{F}$ on A such that the $\mathfrak{T}_p$-limit g_0 of $\mathcal{F}$ is not measurable. Let h_0', h_1' be measurable functions such that $h_0' \leq g_0 \leq h_1'$ and $\int h_0' = \underline{\int} g_0$, $\int h_1' = \overline{\int} g_0$ (133Ja). Then $\delta = \frac{1}{5}\int h_1' - h_0' > 0$ (133Jd). Set $h_0 = h_0' + 2\delta\chi X$, $h_1 = h_1' - 2\delta\chi X$, so that $\int h_0 < \int h_1$.

Set $Q_0 = \{x : x \in X, g_0(x) \leq h_0(x) - \delta\}$. Then $\mu^* Q_0 = 1$. **P?** Otherwise, there is a non-negligible measurable set $F \subseteq X \setminus Q_0$. But in this case $h_0' + \delta\chi F \leq g_0$ and $\underline{\int} g_0 > \int h_0'$, which is impossible. **XQ** Similarly, $\mu^* Q_1 = 1$, where $Q_1 = \{x : g_0(x) \geq h_1(x) + \delta\}$.

If $k \geq 1$, $x_0, \ldots, x_{k-1} \in Q_0$ and $y_0, \ldots, y_{k-1} \in Q_1$, then there is an $f \in A$ such that $|f(x_i) - g_0(x_i)| \leq \delta$, $|f(y_i) - g_0(y_i)| \leq \delta$ for every $i < k$. But this means that $f(x_i) \leq h_0(x_i)$ and $f(y_i) \geq h_1(y_i)$ for every $i < k$, and $(x_0, y_0, \ldots, x_{k-1}, y_{k-1}) \in \tilde{D}_k$. Thus

$$\tilde{D}_k \supseteq Q_0 \times Q_1 \times Q_0 \times Q_1 \times \ldots \times Q_0 \times Q_1,$$

which has full outer measure, by 254L. As k is arbitrary, we have found appropriate h_0, h_1 in this case.

case 2 Now suppose that for every ultrafilter $\mathcal{F}$ on A, the $\mathfrak{T}_p$-limit of $\mathcal{F}$ is measurable.

(i) We are supposing that A is not stable, so there are $E \in \Sigma$ and $\alpha < \beta$ such that $\mu E > 0$ and $(\mu^{2k})^* D_k(A, E, \alpha, \beta) = (\mu E)^{2k}$ for every $k \geq 1$. The first thing to note is that if $\mathcal{I}$ is the set of those $B \subseteq A$ for which there is some $k \in \mathbb{N}$ such that $(\mu^{2k})^* D_k(B, E, \alpha, \beta) < (\mu E)^{2k}$, then $\mathcal{I}$ is an ideal of subsets of A. **P** Of course $\emptyset \in \mathcal{I}$ and $B \in \mathcal{I}$ whenever $B \subseteq B' \in \mathcal{I}$. Also 465Cc tells us that, if $B \in \mathcal{I}$, then $\lim_{k\to\infty} \frac{1}{(\mu E)^{2k}} (\mu^{2k})^* D_k(B, E, \alpha, \beta) = 0$. It follows easily (as in the proof of 465Cd) that $B \cup B' \in \mathcal{I}$ for all B, $B' \in \mathcal{I}$. **Q**

(ii) $\mathcal{I}$ is a proper ideal of subsets of A (by the choice of E, k, α and β), so there is an ultrafilter $\mathcal{F}$ on A such that $\mathcal{F} \cap \mathcal{I} = \emptyset$. Let g_0 be the $\mathfrak{T}_p$-limit of $\mathcal{F}$. Then g_0 is measurable.

Set $\delta = \frac{1}{3}(\beta - \alpha)\mu E > 0$, and define h_0, h_1 by setting

$$h_0(x) = \alpha \text{ if } x \in E, \\ = g_0(x) + \delta \text{ if } x \in X \setminus E, \\ h_1(x) = \beta \text{ if } x \in E, \\ = g_0(x) - \delta \text{ if } x \in X \setminus E.$$

Then

$$\int h_1 - \int h_0 \geq (\beta - \alpha)\mu E - 2\delta\mu(X \setminus E) > 0.$$

(iii) We shall need to know a little more about sets of the form $D_k(B, E, \alpha, \beta)$ for $B \in \mathcal{F}$. In fact, if $B \subseteq A$ and $B \notin \mathcal{I}$, then for any finite sets I and J

$$(\mu^I \times \mu^J)^* D_{I,J}(B, E, \alpha, \beta) = (\mu E)^{\#(I)+\#(J)},$$

where $D_{I,J}(B, E, \alpha, \beta)$ is

$$\bigcup_{f \in B} \{(u, v) : u \in E^I,\ v \in E^J,\ f(u(i)) \leq \alpha \text{ for } i \in I,\ f(v(j)) \geq \beta \text{ for } j \in J\}.$$

P We may suppose that $I = k$ and $J = l$ where $k, l \in \mathbb{N}$. Take $m = \max(1, k, l)$. Then we have an inverse-measure-preserving map $\phi : X^{2m} \to X^I \times X^J$ defined by saying that $\phi(w) = (u, v)$ where $u(i) = w(2i)$ for $i < k$ and $v(i) = w(2i + 1)$ for $i < l$. **?** If $(\mu^I \times \mu^J)^* D_{I,J}(B, E, \alpha, \beta) < (\mu E)^{k+l}$, there is a non-negligible measurable set $V \subseteq (E^I \times E^J) \setminus D_{I,J}(B, E, \alpha, \beta)$. Now $\phi^{-1}[V]$ is non-negligible and depends only on coordinates in $\{2i : i < k\} \cup \{2i + 1 : i < l\}$, so

$$\mu^{2m}(E^{2m} \cap \phi^{-1}[V]) = \mu^{2m}(\phi^{-1}[V]) \cdot (\mu E)^{2m-k-l} > 0.$$

But $\phi^{-1}[V] \cap D_m(B, E, \alpha, \beta) = \emptyset$, so $(\mu^{2m})^* D_m(B, E, \alpha, \beta) < (\mu E)^{2m}$, and $B \in \mathcal{I}$. **X** So $(\mu^I \times \mu^J)^* D_{I,J}(B, E, \alpha, \beta) = (\mu E)^{k+l}$, as required. **Q**

(iv) **?** Suppose, if possible, that $k \geq 1$ is such that $(\mu^{2k})^* \tilde{D}_k < 1$, where $\tilde{D}_k$ is defined from h_0 and h_1 by the formula (*) in the statement of the lemma. Let $W \subseteq X^{2k}$ be a measurable set of positive measure disjoint from $\tilde{D}_k$. For I, $J \subseteq k$ write W_{IJ} for

$$\{w : w \in W, w(2i) \in E \text{ for } i \in I,\ w(2i) \notin E \text{ for } i \in k \setminus I,$$
$$w(2i + 1) \in E \text{ for } i \in J,\ w(2i + 1) \notin E \text{ for } i \in k \setminus J\}.$$

Then there are I, $J \subseteq K$ such that $\mu^{2k} W_{IJ} > 0$.

We can identify X^{2k} with $X^I \times X^J \times X^{k \setminus I} \times X^{k \setminus J}$, matching any $w \in X^{2k}$ with (w_0, w_1, w_2, w_3) where

$$w_0(i) = w(2i) \text{ for } i \in I,$$
$$w_1(i) = w(2i + 1) \text{ for } i \in J,$$
$$w_2(i) = w(2i) \text{ for } i \in k \setminus I,$$
$$w_3(i) = w(2i + 1) \text{ for } i \in k \setminus J.$$

Write $\tilde{W}$ for the image of W_{IJ} under this matching. The condition $W_{IJ} \cap \tilde{D}_k = \emptyset$ translates into

(†) whenever $(w_0, w_1, w_2, w_3) \in \tilde{W}$, $f \in A$,
either there is an $i \in I$ such that $f(w_0(i)) > \alpha$
or there is an $i \in J$ such that $f(w_1(i)) < \beta$
or there is an $i \in k \setminus I$ such that $f(w_2(i)) > g_0(w_2(i)) + \delta$
or there is an $i \in k \setminus J$ such that $f(w_3(i)) < g_0(w_3(i)) - \delta$.

(v) By Fubini's theorem, applied to $(X^I \times X^J) \times (X^{k \setminus I} \times X^{k \setminus J})$, we can find $w_2 \in X^{k \setminus I}$, $w_3 \in X^{k \setminus J}$ such that $(\mu^I \times \mu^J)(V)$ is defined and greater than 0, where $V = \{(w_0, w_1) : (w_0, w_1, w_2, w_3) \in \tilde{W}\}$. Set

$$B = \{f : f \in A, |f(w_2(i)) - g_0(w_2(i))| \leq \delta \text{ for } i \in k \setminus I,$$
$$|f(w_3(i)) - g_0(w_3(i))| \leq \delta \text{ for } i \in k \setminus J\}.$$

Then $B \in \mathcal{F}$, because $\mathcal{F} \to g_0$ for $\mathfrak{T}_p$. So $(\mu^I \times \mu^J)^* D_{I,J}(B, E, \alpha, \beta) = (\mu E)^{\#(I)+\#(J)}$, by (iii) above. Since $W_{IJ} \subseteq W \subseteq E^{2k}$, V is included in $E^I \times E^J$ and meets $D_{I,J}(B, E, \alpha, \beta)$; that is, there are $f \in B$ and $(w_0, w_1) \in V$ such that $f(w_0(i)) \leq \alpha$ for $i \in I$ and $f(w_1(i)) \geq \beta$ for $i \in J$. But because $f \in B$ we also have $f(w_2(i)) \leq g_0(w_2(i)) + \delta$ for $i \in k \setminus I$ and $f(w_3(i)) \geq g_0(w_3(i)) - \delta$ for $i \in k \setminus J$; which contradicts the list in (†) above. **X**

(vi) Thus $(\mu^{2k})^* \tilde{D}_k = 1$ for every k, and in this case also we have an appropriate pair h_0, h_1.

465M Theorem (TALAGRAND 82, TALAGRAND 87) Let (X, Σ, μ) be a complete probability space, and A a non-empty uniformly bounded set of real-valued functions defined on X. Then the following are equiveridical:

(i) A is stable.

(ii) Every function in A is measurable, and $\lim_{k\to\infty} \sup_{f\in A} |\frac{1}{k}\sum_{i=0}^{k-1} f(w(i)) - \int f| = 0$ for almost every $w \in X^{\mathbb{N}}$.

(iii) Every function in A is measurable, and for every $\epsilon > 0$ there are a finite subalgebra T of Σ in which every atom of T is non-negligible and a sequence $\langle h_k\rangle_{k\geq 1}$ of measurable functions on $X^{\mathbb{N}}$ such that

$$h_k(w) \geq \sup_{f\in A} \frac{1}{k}\sum_{i=0}^{k-1} \big|f(w(i)) - \mathbb{E}(f|\mathrm{T})(w(i))\big|$$

for every $w \in X^{\mathbb{N}}$, $k \geq 1$, and

$$\limsup_{k\to\infty} h_k(w) \leq \epsilon$$

for almost every $w \in X^{\mathbb{N}}$. (Here $\mathbb{E}(f|\mathrm{T})$ is the (unique) conditional expectation of f on T.)

(iv) $\lim_{k,l\to\infty} \sup_{f\in A} |\frac{1}{k}\sum_{i=0}^{k-1} f(w(i)) - \frac{1}{l}\sum_{i=0}^{l-1} f(w(i))| = 0$ for almost every $w \in X^{\mathbb{N}}$.

(v) $\lim_{k,l\to\infty} \overline{\int} \sup_{f\in A} |\frac{1}{k}\sum_{i=0}^{k-1} f(w(i)) - \frac{1}{l}\sum_{i=0}^{l-1} f(w(i))| \mu^{\mathbb{N}}(dw) = 0$.

proof All the statements (i)-(v) are unaffected by translations (by constant functions) and scalar multiplications of the set A, so it will be enough to consider the case in which $A \subseteq [0,1]^X$.

As in 465I-465H, I write $\nu_{wk}(E) = \frac{1}{k}\#(\{i : i < k, w(i) \in E\})$ for $w \in X^{\mathbb{N}}$, $k \geq 1$ and $E \subseteq X$; so for any function $f : X \to \mathbb{R}$, $\int f d\nu_{wk} = \frac{1}{k}\sum_{i=0}^{r-1} f(w(i))$.

(a)(i)⇒(iii)(α) If A is stable, then every function in A is measurable, by 465Da. Let $\epsilon > 0$. Set $\eta = \frac{1}{27}\epsilon^2 > 0$. By 465Db, the $\mathfrak{T}_p$-closure $\overline{A}$ of A in $\mathbb{R}^X$ is a $\mathfrak{T}_p$-compact set of measurable functions, and by 465G it is $\mathfrak{T}_m$-compact; because A is uniformly bounded, it must be totally bounded for the norm $\|\ \|_1$. So there are $f_0, \dots, f_m \in A$ such that for every $f \in A$ there is an $i \leq m$ such that $\|f - f_i\|_1 \leq \eta$. Let T_0 be the finite subalgebra of Σ generated by the sets $\{x : j\eta \leq f_i(x) < (j+1)\eta\}$ for $i \leq m$ and $j \leq \frac{1}{\eta}$. Then T_0 may have negligible atoms, but if we absorb these into non-negligible atoms we get a finite subalgebra T of Σ such that $|f_i(x) - \mathbb{E}(f_i|\mathrm{T})(x)| \leq \eta$ for almost every $x \in X$, every $i \leq m$. (Because T is a finite algebra with non-negligible atoms, two T-measurable functions which are equal almost everywhere must be identical, and we have unique conditional expectations with respect to T.) Since $\|\mathbb{E}(f|\mathrm{T}) - \mathbb{E}(g|\mathrm{T})\|_1 \leq \|f - g\|_1$ for all integrable functions f and g (242Je), $\|f - \mathbb{E}(f|\mathrm{T})\|_1 \leq 3\eta$ for every $f \in A$.

(β) Set $A' = \{f - \mathbb{E}(f|\mathrm{T}) : f \in A\}$. Then A' is stable. **P** Suppose that $\mu E > 0$ and $\alpha < \beta$. The set $B = \{\mathbb{E}(f|\mathrm{T}) : f \in A\}$ is a uniformly bounded subset of a finite-dimensional space of functions, so is $\|\ \|_\infty$-compact. So there are $g_0, \dots, g_r \in B$ such that $B \subseteq \bigcup_{i\leq r}\{g : \|g - g_i\|_\infty \leq \frac{1}{3}(\beta - \alpha)\}$. By 465Cf and 465Cd, $C = \bigcup_{i\leq r} A - g_i$ is stable. So there is a $k \geq 1$ such that

$$(\mu^{2k})^* D_k(C, E, \tfrac{2}{3}\alpha + \tfrac{1}{3}\beta, \tfrac{1}{3}\alpha + \tfrac{2}{3}\beta) < (\mu E)^{2k}.$$

But for every $g \in A'$ there is an $h \in C$ such that $\|g - h\|_\infty \leq \frac{1}{3}(\beta - \alpha)$, so

$$D_k(A', E, \alpha, \beta) \subseteq D_k(C, E, \tfrac{2}{3}\alpha + \tfrac{1}{3}\beta, \tfrac{1}{3}\alpha + \tfrac{2}{3}\beta),$$

$$(\mu^{2k})^* D_k(A', E, \alpha, \beta) < (\mu E)^{2k}.$$

As E, α and β are arbitrary, A' is stable. **Q**

(γ) By 465Ch, $\{|g| : g \in A'\}$ is stable. By 465K there are an $n \geq 1$, a $W \in \widehat{\bigotimes}_n \Sigma$ and a $\gamma > \mu^n W$ such that $\int |g| d\nu \leq 3\sqrt{3\eta} = \epsilon$ whenever $g \in A'$ and ν is a probability measure on X, with domain Σ, such that $\nu^n W \leq \gamma$. Now ν_{wk} is a probability measure on X; set $q_k(w) = \nu_{wk}^n(W)$. Applying 465H to the characteristic function of W, we see that $\lim_{k\to\infty} q_k(w) = \mu^n W$ for almost every $w \in X^{\mathbb{N}}$. Also, because $W \in \widehat{\bigotimes}_n \Sigma$, every q_k is measurable, by 465I.

Set $h_k(w) = 1$ if $q_k(w) > \gamma$, ϵ if $q_k(w) \leq \gamma$. Then every h_k is measurable and $\lim_{k\to\infty} h_k(w) = \epsilon$ for almost every w.

For any $w \in X^{\mathbb{N}}$ and any $f \in A$, $g = f - \mathbb{E}(f|\mathrm{T}) \in A'$ and $\|g\|_\infty \leq 1$. So either $h_k(w) = 1$ and certainly $\int |g| d\nu_{wk} \leq h_k(w)$, or $h_k(w) = \epsilon$, $\nu^n_{wk}(W) \leq \gamma$ and $\int |g| d\nu_{wk} \leq \epsilon$. Thus we have

$$\tfrac{1}{k}\textstyle\sum_{i=0}^{k-1} \big|f(w(i)) - \mathbb{E}(f|\mathrm{T})(w(i))\big| = \int \big|f - \mathbb{E}(f|\mathrm{T})\big| d\nu_{wk} \leq h_k(w)$$

for every $w \in X^{\mathbb{N}}$ and every $f \in A$, as required by (iii).

(b)(iii)⇒(ii) & (v) Set

$$g_k(w) = \sup_{f\in A} |\tfrac{1}{k}\textstyle\sum_{i=0}^{k-1} f(w(i)) - \int f d\mu|,$$

$$g'_{kl}(w) = \sup_{f\in A} |\tfrac{1}{k}\textstyle\sum_{i=0}^{k-1} f(w(i)) - \tfrac{1}{l}\sum_{i=0}^{l-1} f(w(i))|,$$

for $w \in X^{\mathbb{N}}$ and k, $l \geq 1$. Let $\epsilon > 0$. Let T, $\langle h_k\rangle_{k\geq 1}$ be as in (iii), and let $E_0, \dots, E_r$ be the atoms of T. For $w \in X^{\mathbb{N}}$, $k \geq 1$, $j \leq r$ set $q_{kj}(w) = |\mu E_j - \nu_{wk} E_j|$. Then for any $f \in A$, $\mathbb{E}(f|\mathrm{T})$ is expressible as $\sum_{j=0}^r \alpha_j \chi E_j$ where $\alpha_j \in [0,1]$ for every j (remember that $A \subseteq [0,1]^X$), so

$$\begin{aligned}
|\tfrac{1}{k}\sum_{i=0}^{k-1} f(w(i)) - \int f d\mu| &= |\int f d\nu_{wk} - \int f d\mu| \\
&\leq |\int f d\nu_{wk} - \int \mathbb{E}(f|\mathrm{T}) d\nu_{wk}| + |\int \mathbb{E}(f|\mathrm{T}) d\nu_{wk} - \int \mathbb{E}(f|\mathrm{T}) d\mu| \\
&\leq \tfrac{1}{k}\sum_{i=0}^{k-1} \big|f(w(i)) - \mathbb{E}(f|\mathrm{T})(w(i))\big| + \sum_{j=0}^r \alpha_j \big|\mu E_j - \nu_{wk} E_j\big| \\
&\leq h_k(w) + \sum_{j=0}^r q_{kj}(w), \\
|\tfrac{1}{k}\sum_{i=0}^{k-1} f(w(i)) - \tfrac{1}{l}\sum_{i=0}^{l-1} f(w(i))\big| & \\
&\leq h_k(w) + \sum_{j=0}^r q_{kj}(w) + h_l(w) + \sum_{j=0}^r q_{lj}(w).
\end{aligned}$$

Taking the supremum over f, we have

$$g_k(w) \leq h_k(w) + \textstyle\sum_{j=0}^r q_{kj}(w),$$

$$g'_{kl}(w) \leq h_k(w) + \textstyle\sum_{j=0}^r q_{kj}(w) + \sum_{j=0}^r q_{lj}(w) + h_l(w).$$

But, for each $j \leq r$, $\lim_{k\to\infty} q_{kj}(w) = 0$ for almost every w, by 465H (or 273J) applied to the characteristic function of E_j. So

$$\limsup_{k\to\infty} g_k(w) \leq \limsup_{k\to\infty} h_k(w) \leq \epsilon$$

for almost every w. At the same time,

$$\limsup_{k,l\to\infty} \overline{\textstyle\int} g'_{kl} \leq \limsup_{k,l\to\infty} \textstyle\int h_k + \sum_{j=0}^r \int q_{kj} + \sum_{j=0}^r \int q_{lj} + \int h_l \leq 2\epsilon.$$

As ϵ is arbitrary, $\{w : \limsup_{k\to\infty} g_k(w) \geq 2^{-i}\}$ is negligible for every $i \in \mathbb{N}$, and $\lim_{k\to\infty} g_k = 0$ almost everywhere, as required, while equally $\lim_{k,l\to\infty} \overline{\int} g'_{kl} = 0$. Thus (ii) and (v) are true.

(c)(ii)⇒(iv) is trivial, since

$$|\tfrac{1}{k}\sum_{i=0}^{k-1} f(w(i)) - \tfrac{1}{l}\sum_{i=0}^{l-1} f(w(i))| \leq |\tfrac{1}{k}\sum_{i=0}^{k-1} f(w(i)) - \int f| + |\tfrac{1}{l}\sum_{i=0}^{l-1} f(w(i)) - \int f|.$$

(d) not-(i)⇒not-(iv) & not-(v) Now suppose that A is not stable.

(α) In this case, by 465L, there are measurable functions h_0, $h_1 : X \to [0,1]$ such that $\int h_0 d\mu < \int h_1 d\mu$ and $(\mu^{2k})^* \tilde{D}_k = 1$ for every $k \in \mathbb{N}$, where

$$\tilde{D}_k = \bigcup_{f \in A} \{w : w \in X^{2k}, f(w(2i)) \le h_0(w(2i)), \\ f(w(2i+1)) \ge h_1(w(2i+1)) \text{ for every } i < k\}.$$

(β) Set $\delta = \frac{1}{4}\int h_1 - h_0 > 0$. Let $k_0 \ge 1$ be so large that

$$\mu^k\{w : w \in X^k, |\int h_j - \tfrac{1}{k}\textstyle\sum_{i=0}^{k} h_j(w(i))| \le \delta\} \ge \frac{1}{2}$$

for both j and for every $k \ge k_0$ (273J or 465H. The point is that

$$\begin{aligned}\mu^k\{w : w \in X^k, |\int h_j - \frac{1}{k}\sum_{i=0}^{k} h_j(w(i))| \le \delta\} \\ &= \mu^{\mathbb{N}}\{w : w \in X^{\mathbb{N}}, |\int h_j - \frac{1}{k}\sum_{i=0}^{k} h_j(w(i))| \le \delta\} \\ &\to 1 \text{ as } k \to \infty.)\end{aligned}$$

Let $\langle k_n\rangle_{n\ge 1}$ be such that $k_n \ge \frac{2}{\delta}\sum_{i=0}^{n-1} k_i$ for every $n \ge 1$. Since $\delta \le \frac{1}{4}$, every k_n is at least as large as k_0.

(γ) Set $m_n = 2\sum_{i<n} k_i$ for each $n \in \mathbb{N}$. Then we have a measure space isomorphism $\phi : \prod_{n\in\mathbb{N}} X^{2k_n} \to X^{\mathbb{N}}$ defined by setting

$$\phi(w)(m_n + i) = w(n)(2i), \quad \phi(w)(m_n + k_n + i) = w(n)(2i+1)$$

for $n \in \mathbb{N}$ and $i < k_n$. For each $n \in \mathbb{N}$, $\tilde{D}_{k_n}$ has outer measure 1 in X^{2k_n}, so $\tilde{D} = \prod_{n\in\mathbb{N}} \tilde{D}_{k_n}$ has outer measure 1 in $\prod_{n\in\mathbb{N}} X^{2k_n}$, and $\phi[\tilde{D}]$ has outer measure 1 in $X^{\mathbb{N}}$. Note that $\phi[\tilde{D}]$ is just the set of $w \in X^{\mathbb{N}}$ such that, for every $n \in \mathbb{N}$, there is an $f \in A$ such that

$$f(w(i)) \le h_0(w(i)) \text{ for } m_n \le i < m_n + k_n,$$
$$f(w(i)) \ge h_1(w(i)) \text{ for } m_n + k_n \le i < m_n + 2k_n = m_{n+1}.$$

If we set

$$V_{n0} = \{w : w \in X^{\mathbb{N}}, |\tfrac{1}{k_n}\textstyle\sum_{i=m_n}^{m_n+k_n-1} h_0(w(i)) - \int h_0| \le \delta\},$$

$$V_{n1} = \{w : w \in X^{\mathbb{N}}, |\tfrac{1}{k_n}\textstyle\sum_{i=m_n+k_n}^{m_n+2k_n-1} h_1(w(i)) - \int h_1| \le \delta\},$$

every V_{n0} and V_{n1} has measure at least $\frac{1}{2}$, because $k_n \ge k_0$.

(δ) Now suppose that $n \in \mathbb{N}$ and $w \in V_{n0} \cap V_{n1} \cap \phi[\tilde{D}]$. Then

$$\sup_{f\in A} \Big|\frac{1}{m_n+2k_n}\sum_{i=0}^{m_n+2k_n-1} f(w(i)) - \frac{1}{m_n+k_n}\sum_{i=0}^{m_n+k_n-1} f(w(i))\Big| \ge \frac{\delta}{(2+\delta)(1+\delta)}.$$

P Since $w \in \phi[\tilde{D}]$, there must be an $f \in A$ such that

$$f(w(i)) \le h_0(w(i)) \text{ for } m_n \le i < m_n + k_n,$$
$$f(w(i)) \ge h_1(w(i)) \text{ for } m_n + k_n \le i < m_n + 2k_n = m_{n+1}.$$

Set $s = \sum_{i=0}^{m_n-1} f(w(i))$, $t = \sum_{i=m_n}^{m_n+k_n} f(w(i))$ and $t' = \sum_{i=m_n+k_n}^{m_n+2k_n-1} f(w(i))$. Then

$$\begin{aligned}\frac{1}{m_n+2k_n}\sum_{i=0}^{m_n+2k_n-1} f(w(i)) - \frac{1}{m_n+k_n}\sum_{i=0}^{m_n+k_n-1} f(w(i))\\ &= \frac{s+t+t'}{m_n+2k_n} - \frac{s+t}{m_n+k_n} = \frac{(t'-t-s)k_n + t'm_n}{(m_n+2k_n)(m_n+k_n)}\\ &\geq \frac{(t'-t-m_n)k_n}{(m_n+2k_n)(m_n+k_n)} \geq \frac{t'-t-\delta k_n}{(2+\delta)(1+\delta)k_n}\end{aligned}$$

because $m_n \leq \delta k_n$, by the choice of k_n.

To estimate t and t', we have

$$t = \textstyle\sum_{i=m_n}^{m_n+k_n-1} f(w(i)) \leq \sum_{i=m_n}^{m_n+k_n-1} h_0(w(i)) \leq k_n(\int h_0 + \delta)$$

because $w \in V_{n0}$. On the other hand,

$$t' = \textstyle\sum_{i=m_n+k_n}^{m_n+2k_n-1} f(w(i)) \geq \sum_{i=m_n+k_n}^{m_n+2k_n-1} h_1(w(i)) \geq k_n(\int h_1 - \delta)$$

because $w \in V_{n1}$. So

$$t' - t \geq k_n(\textstyle\int h_1 - h_0 - 2\delta) = 2k_n\delta,$$

and

$$\begin{aligned}\frac{1}{m_n+2k_n}\sum_{i=0}^{m_n+2k_n-1} f(w(i)) - \frac{1}{m_n+k_n}\sum_{i=0}^{m_n+k_n-1} f(w(i))\\ &\geq \frac{2\delta k_n - \delta k_n}{(2+\delta)(1+\delta)k_n} = \frac{\delta}{(2+\delta)(1+\delta)}. \blacksquare\end{aligned}$$

(ϵ) The V_{n0} and V_{n1} are all independent. So $\mu^{\mathbb{N}}(V_{n0} \cap V_{n1}) \geq \frac{1}{4}$ for every n, and

$$W = \{w : w \in X^{\mathbb{N}}, \, w \in V_{n0} \cap V_{n1} \text{ for infinitely many } n\}$$

has measure 1 (by the Borel-Cantelli lemma, 273K, or otherwise). Accordingly $W \cap \phi[\tilde{D}]$ has outer measure 1 in $X^{\mathbb{N}}$. But if $w \in W \cap \phi[\tilde{D}]$, then (δ) tells us that

$$\limsup_{k,l\to\infty} \sup_{f\in A} \big|\frac{1}{k}\sum_{i=0}^{k-1} f(w(i)) - \frac{1}{l}\sum_{i=0}^{l-1} f(w(i))\big| \geq \frac{\delta}{(2+\delta)(1+\delta)},$$

because there are infinitely many n such that $w \in V_{n0} \cap V_{n1} \cap \phi[\tilde{D}]$. So (iv) must be false.

(ζ) We see also that, for any $n \in \mathbb{N}$,

$$\begin{aligned}\overline{\int} g'_{m_n+k_n, m_n+2k_n} &\geq \frac{\delta}{(2+\delta)(1+\delta)}\mu^{\mathbb{N}}(V_{n0} \cap V_{n1})\\ &\geq \frac{\delta}{4(2+\delta)(1+\delta)},\end{aligned}$$

writing

$$g'_{kl}(w) = \sup_{f\in A} |\tfrac{1}{k}\textstyle\sum_{i=0}^{k-1} f(w(i)) - \frac{1}{l}\sum_{i=0}^{l-1} f(w(i))|$$

for k, $l \in \mathbb{N}$. So $\limsup_{k,l\to\infty} \overline{\int} g'_{kl} > 0$, and (v) is false.

465N Corollary (Talagrand 84) Let (X, Σ, μ) be a measure space.

(a) Let $A \subseteq \mathbb{R}^X$ be a stable set. Suppose that there is a measurable function $g : X \to [0, \infty[$ such that $|f(x)| \leq g(x)$ for every $x \in X$, $f \in A$. Then the convex hull $\Gamma(A)$ of A in $\mathbb{R}^X$ is stable.

(b) Let A, $B \subseteq \mathbb{R}^X$ be two stable sets. Suppose that that there is a measurable function $g : X \to [0, \infty[$ such that $|f(x)| \leq g(x)$ for every $x \in X$, $f \in A \cup B$. Then $A + B = \{f_1 + f_2 : f_1 \in A, \, f_2 \in B\}$ is stable.

proof (a)(i) Consider first the case in which $\mu X = 1$ and $A \subseteq [-1,1]^X$. In this case,

$$\sup_{f\in\Gamma(A)} |\tfrac{1}{k}\sum_{i=0}^{k-1} f(w(i)) - \int f| = \sup_{f\in A} |\tfrac{1}{k}\sum_{i=0}^{k-1} f(w(i)) - \int f|$$

for every $k \geq 1$, $w \in X^{\mathbb{N}}$. So $\Gamma(A)$ satisfies condition (ii) of 465M whenever A does, and we have the result.

(ii) Now suppose just that $\mu X = 1$. Set $A' = \{\frac{f}{1+g} : f \in A\}$. Then A' is stable (465Ci), so $\Gamma(A')$ is stable, by (i), and $\Gamma(A) = \{f \times (1+g) : f \in A'\}$ is stable.

(iii) For the general case, take $E \in \Sigma$ and $\alpha < \beta$ such that $0 < \mu E < \infty$. Let ν be the indefinite-integral measure defined by μ and the function $(\mu E)^{-1}\chi E$. Then A is stable with respect to ν (465Ck), so $\Gamma(A)$ is stable with respect to ν, by (ii). There is therefore some $k \geq 1$ such that $(\nu^{2k})^* D_k(\Gamma(A), E, \alpha, \beta) < 1$. But (because ν^{2k} is the indefinite integral of $(\mu E)^{-2k}\chi E^{2k}$) $(\mu^{2k})^* D_k(\Gamma(A), E, \alpha, \beta) < (\mu E)^{2k}$. As E, α and β are arbitrary, $\Gamma(A)$ is stable with respect to μ.

(b) $A + B \subseteq 2\Gamma(A \cup B)$, so the result follows from 465Cd, (a) and 465Ce.

465O Stable sets in L^0 The notion of 'stability' as defined in 465B is applicable only to true functions; in such examples as 465Xj, the irregularity of the set A is erased entirely if we look at its image in the space L^0 of equivalence classes of measurable functions. We do, however, have a corresponding concept for subsets of function spaces, which can be expressed in the language of §325. If $(\mathfrak{A}, \bar\mu)$ is a semi-finite measure algebra, and $k \geq 1$, I write $(\widehat{\bigotimes}_k \mathfrak{A}, \bar\mu^k)$ for the localizable measure algebra free product of k copies of $(\mathfrak{A}, \bar\mu)$, as described in 325H. If $Q \subseteq L^0(\mathfrak{A})$, $k \geq 1$, $a \in \mathfrak{A}$ has finite measure and $\alpha < \beta$ in $\mathbb{R}$, set

$$d_k(Q, a, \alpha, \beta) = \sup_{v\in Q}(a \cap [\![v \leq \alpha]\!]) \otimes (a \cap [\![v \geq \beta]\!]) \otimes \ldots \otimes (a \cap [\![v \leq \alpha]\!]) \otimes (a \cap [\![v \geq \beta]\!])$$

in $\widehat{\bigotimes}_{2k}\mathfrak{A}$, taking k repetitions of the formula $(a \cap [\![v \leq \alpha]\!]) \otimes (a \cap [\![v \geq \beta]\!])$ to match the corresponding formula

$$D_k(A, E, \alpha, \beta) = \bigcup_{f\in A}((E \cap \{x : f(x) \leq \alpha\}) \times (E \cap \{x : f(x) \geq \beta))^k.$$

(Note that the supremum $\sup_{v\in Q} \ldots$ is defined because $a^{\otimes 2k} = a \otimes \ldots \otimes a$ has finite measure in the measure algebra $(\widehat{\bigotimes}_{2k}\mathfrak{A}, \bar\mu^{2k})$. Of course I mean to take $d_k(Q, a, \alpha, \beta) = 0$ if $Q = \emptyset$.) Now we can say that Q is **stable** if whenever $0 < \bar\mu a < \infty$ and $\alpha < \beta$ there is a $k \geq 1$ such that $\bar\mu^{2k} d_k(Q, a, \alpha, \beta) < (\bar\mu a)^{2k}$; that is, $d_k(Q, a, \alpha, \beta) \neq a \otimes \ldots \otimes a$.

We have the following relationships between the two concepts of stability.

465P Theorem Let (X, Σ, μ) be a semi-finite measure space, with measure algebra $(\mathfrak{A}, \bar\mu)$.

(a) Suppose that $A \subseteq \mathcal{L}^0(\Sigma)$ and that $Q = \{f^\bullet : f \in A\} \subseteq L^0(\mu)$, identified with $L^0 = L^0(\mathfrak{A})$ (364Jc). Then Q is stable in the sense of 465O iff every countable subset of A is stable in the sense of 465B.

(b) If μ is strictly localizable and $Q \subseteq L^0(\mu)$ is stable, then there is a stable set $B \subseteq \mathcal{L}^0$ such that $Q = \{f^\bullet : f \in B\}$.

proof (a)(i) Suppose that all countable subsets of A are stable, and take $a \in \mathfrak{A}$ such that $0 < \bar\mu a < \infty$ and $\alpha < \beta$ in $\mathbb{R}$. For each $k \in \mathbb{N}$ there is a countable set $Q_k \subseteq Q$ such that $d_k(Q_k, a, \alpha, \beta) = d_k(Q, a, \alpha, \beta)$, because $a^{\otimes 2k}$ is of finite measure in $\widehat{\bigotimes}_{2k}\mathfrak{A}$. Now there is a countable set $A' \subseteq A$ such that $\{f^\bullet : f \in A'\} = \bigcup_{k\in\mathbb{N}} Q_k$. Let $E \in \Sigma$ be such that $E^\bullet = a$. As $\mu E = \bar\mu a \in]0, \infty[$ and A' is stable, there is a $k \geq 1$ such that $(\mu^{2k})^* D_k(A', E, \alpha, \beta) < (\mu E)^{2k}$. Because A' is countable, $D_k(A', E, \alpha, \beta)$ is measurable. But 325He tells us that we have an order-continuous measure-preserving Boolean homomorphism π from the measure algebra of μ^{2k} to $\widehat{\bigotimes}_{2k}\mathfrak{A}$, such that $\pi(\prod_{i<2k} F_i)^\bullet = F_0^\bullet \otimes \ldots \otimes F_{2k-1}^\bullet$ for all $F_0, \ldots, F_{2k-1} \in \Sigma$; accordingly

$$\begin{aligned}\bar\mu^{2k} d_k(Q, a, \alpha, \beta) &= \bar\mu^{2k} d_k(Q_k, a, \alpha, \beta) \leq \bar\mu^{2k} d_k(\bigcup_{i\in\mathbb{N}} Q_i, a, \alpha, \beta)\\ &= \bar\mu^{2k}(\pi D_k(A', E, \alpha, \beta)^\bullet) = \mu^{2k} D_k(A', E, \alpha, \beta)\\ &< (\mu E)^{2k} = \bar\mu^{2k} a^{\otimes 2k}.\end{aligned}$$

As a, α and β are arbitrary, Q is stable.

(ii) Now suppose that Q is stable and that A' is any countable subset of A. Take $E \in \Sigma$ such that $0 < \mu E < \infty$, and $\alpha < \beta$ in $\mathbb{R}$. Set $a = E^\bullet \in \mathfrak{A}$. This time, writing Q' for $\{f^\bullet : f \in A'\}$, we have

$$\pi D_k(A', E, \alpha, \beta)^\bullet = d_k(Q', a, \alpha, \beta) \subseteq d_k(Q, a, \alpha, \beta)$$

for every $k \geq 1$. There is some k such that $d_k(Q, a, \alpha, \beta) \neq a^{\otimes 2k}$, and in this case $\mu^{2k} D_k(A', E, \alpha, \beta) < (\mu E)^{2k}$; as E, α and β are arbitrary, A' is stable.

(b)(i) If $\mu X = 0$ this is trivial; suppose that $\mu X > 0$. Replacing μ by its completion does not change either $L^0(\mu)$ or the stable subsets of $\mathbb{R}^X$ (241Xb, 465Cj), and leaves μ strictly localizable (212Ga), so we may suppose that μ is complete. Let $\langle E_i \rangle_{i \in I}$ be a decomposition of X into sets of finite measure. Amalgamating any negligible E_i into other non-negligible ones, we may suppose that $\mu E_i > 0$ for each i. Writing μ_i for the subspace measure on E_i, we have a consistent lifting ϕ_i for μ_i (346J). Set $\phi E = \bigcup_{i \in I} \phi_i(E \cap X_i)$ for $E \in \Sigma$; then ϕ is a lifting of μ. Let θ be the corresponding lifting from $\mathfrak{A}$ to Σ (341B) and $T : L^\infty(\mathfrak{A}) \to \mathfrak{L}^\infty(\Sigma)$ the associated linear operator, defined by saying that $T(\chi a) = \chi(\theta a)$ for every $a \in \mathfrak{A}$ (363F). Since $\theta(a)^\bullet = a$ for every $a \in \mathfrak{A}$, $(Tv)^\bullet = v$ for every $v \in L^\infty$.

(ii) We need to know that if $v \in L^\infty$ and $\alpha < \alpha'$, then $\{x : (Tv)(x) \leq \alpha\} \subseteq \phi(\{x : (Tv)(x) \leq \alpha'\})$. **P** Let $v' \in S(\mathfrak{A})$ be such that $\|v - v'\|_\infty \leq \frac{1}{2}(\alpha' - \alpha)$ (363C), and set $\gamma = \frac{1}{2}(\alpha + \alpha')$. Express v' as $\sum_{i=0}^n \alpha_i \chi a_i$ where $a_0, \ldots, a_n \in \mathfrak{A}$ are disjoint. Then $Tv' = \sum_{i=0}^n \alpha_i \chi(\theta a_i)$. Now

$$\|Tv - Tv'\|_\infty \leq \|v - v'\|_\infty \leq \gamma - \alpha,$$

so

$$\begin{aligned}\{x : (Tv)(x) \leq \alpha\} &\subseteq \{x : (Tv')(x) \leq \gamma\} \\ &= \bigcup \{\theta a_i : i \leq n,\ \alpha_i \leq \gamma\} = \phi(\bigcup \{\theta a_i : i \leq n,\ \alpha_i \leq \gamma\}) \\ &\text{(because } \phi(\theta a) = \theta a \text{ for every } a \in \mathfrak{A}) \\ &= \phi(\{x : (Tv')(x) \leq \gamma\}) \subseteq \phi(\{x : (Tv)(x) \leq \alpha'\}),\end{aligned}$$

as claimed. **Q**

Similarly, if $\beta' < \beta$ then $\{x : (Tv)(x) \geq \beta\} \subseteq \phi(\{x : (Tv)(x) \geq \beta'\})$.

(iii) For the moment, suppose that $Q \subseteq L^\infty(\mathfrak{A})$, which we may identify with $L^\infty(\mu)$ (363I). Set $B = T[Q]$, so that $Q = \{f^\bullet : f \in A\}$. Then B is stable. **P** Let $E \in \Sigma$ be such that $0 < \mu E < \infty$, and $\alpha < \beta$. Let $i \in I$ be such that $\mu(E \cap E_i) > 0$, and α', $\beta' \in \mathbb{R}$ such that $\alpha < \alpha' < \beta' < \beta$. Setting $a = (E \cap E_i)^\bullet$, we have $0 < \bar{\mu} a < \infty$, so there is some $k \in \mathbb{N}$ such that $d_k(Q, a, \alpha', \beta') \neq a^{\otimes 2k}$. Let π be the measure-preserving Boolean homomorphism from the measure algebra of μ^{2k} to $\widehat{\bigotimes}_{2k} \mathfrak{A}$ described in part (a) of this proof; as noted in 325He, the present context is enough to ensure that π is an isomorphism. So there is a $W \in \operatorname{dom} \mu^{2k}$ such that $\pi W^\bullet = d_k(Q, a, \alpha', \beta')$; since

$$d_k(Q, a, \alpha', \beta') \subseteq a^{\otimes 2k} \subseteq (E_i^{2k})^\bullet,$$

we may suppose that $W \subseteq E_i^{2k}$. If $f \in B$, then

$$\pi D_k(\{f\}, E, \alpha', \beta') = d_k(\{f^\bullet\}, a, \alpha', \beta') \subseteq d_k(Q, a, \alpha', \beta'),$$

so $D_k(\{f\}, E, \alpha', \beta') \setminus W$ is negligible.

At this point, recall that ϕ_i was supposed to be a consistent lifting of μ_i. So we have a lifting ϕ' of μ_i^{2k} such that $\phi'(\prod_{j<2k} F_j) = \prod_{j<2k} \phi_i F_j$ for all $F_0, \ldots, F_{2k-1} \in \Sigma_i$. In particular, if $f \in B$ and we set

$$F_{2j} = \{x : x \in E \cap E_i,\ f(x) \leq \alpha\}, \quad F_{2j+1} = \{x : x \in E \cap E_i,\ f(x) \geq \beta\},$$

$$F'_{2j} = \{x : x \in E \cap E_i,\ f(x) \leq \alpha'\}, \quad F'_{2j+1} = \{x : x \in E \cap E_i,\ f(x) \geq \beta'\},$$

for $j < k$, we shall have

$$\prod_{j<2k} F_j \subseteq \prod_{j<2k} \phi F'_j$$

(by (ii) above, because $f = Tv$ for some v)

$$= \prod_{j<2k} \phi_i F'_j = \phi'(\prod_{j<2k} F'_j) \subseteq \phi' W$$

because $\prod_{j<2k} F'_j = D_k(\{f\}, E, \alpha', \beta')$. As f is arbitrary, $D_k(B, E \cap E_i, \alpha, \beta) \subseteq \phi' W$. But now

$$(\mu^{2k})^* D_k(B, E \cap E_i, \alpha, \beta) \leq \mu^{2k}(\phi' W) = \mu_i^{2k}(\phi' W)$$

(251Wl)

$$= \mu_i^{2k} W = \mu^{2k} W$$
$$= \bar{\mu}^{2k} d_k(Q, a, \alpha', \beta') < \bar{\mu}^{2k} a^{\otimes 2k} = \mu(E \cap E_i)^{2k}.$$

As usual, it follows that $(\mu^{2k})^* D_k(B, E, \alpha, \beta) < (\mu E)^{2k}$; as E, α and β are arbitrary, B is stable, as claimed. **Q**

(iv) Thus the result is true if Q is included in the unit ball of L^∞. In general, set $h(\alpha) = \tanh \alpha$ for $\alpha \in \mathbb{R}$, and consider $A' = \{hf : f \in A\}$, $Q' = \{(hf)^\bullet : f \in A\}$. Since every countable subset of A is stable, so is every countable subset of A' (465Cl) and Q' is stable (by (a) of this theorem). But Q' is included in the unit ball of L^∞, so there is a stable set $B' \subseteq \mathcal{L}^0$ such that $Q' = \{g^\bullet : g \in B'\}$. Setting $B = \{h^{-1}g : g \in B'\}$, B is stable and $\{f^\bullet : f \in B\} = Q$. So we have the general theorem.

465Q Remarks Using 465Pa, we can work through the first part of this section to get a list of properties of stable subsets of L^0. For instance, the convex hull of an order-bounded stable set in L^0 is stable, as in 465Na. It is harder to relate such results as 465M to the idea of stability in L^0, but the argument of 465Pb gives a line to follow: if (X, Σ, μ) is complete and strictly localizable, there is a linear operator $T : L^\infty(\mu) \to \mathcal{L}^\infty(\Sigma)$, defined from a lifting, such that, for $Q \subseteq L^\infty$, $T[Q]$ is stable iff Q is stable. So when μ is a complete probability measure, we can look at the averages $\psi_{wk}(v) = \frac{1}{k}\sum_{i=0}^{k-1}(Tv)(w(i))$ for $v \in Q$, $w \in X^{\mathbb{N}}$ to devise criteria for stability of Q in terms of the linear functionals ψ_{wk}.

Working in L^1, however, we can look for results of a different type, as follows.

465R Theorem (Talagrand 84) Let $(\mathfrak{A}, \bar{\mu})$ and $(\mathfrak{B}, \bar{\nu})$ be measure algebras, and $T : L^1(\mathfrak{A}, \bar{\mu}) \to L^1(\mathfrak{B}, \bar{\nu})$ a bounded linear operator. If Q is stable and order-bounded in $L^1(\mathfrak{A}, \bar{\mu})$, then $T[Q] \subseteq L^1(\mathfrak{B}, \bar{\nu})$ is stable.

proof (a) To begin with (down to (d) below) let us suppose that

$(\mathfrak{A}, \bar{\mu})$ and $(\mathfrak{B}, \bar{\nu})$ are the measure algebras of measure spaces (X, Σ, μ) and (Y, T, ν),

so that we can identify $L^1_{\bar{\mu}}$, $L^1_{\bar{\nu}}$ with $L^1(\mu)$ and $L^1(\nu)$ (365B),

Q is countable,

so that Q can be expressed as $\{f^\bullet : f \in A\}$, where $A \subseteq \mathcal{L}^0(\Sigma)$ is countable and stable (465P),

T is positive,

μ and ν are totally finite,

$T(\chi X^\bullet) = \chi Y^\bullet$,

$Q \subseteq L^\infty(\mathfrak{A})$ is $\| \|_\infty$-bounded,

so that we may take $A \subseteq \mathcal{L}^\infty$ to be $\| \|_\infty$-bounded,

$\nu Y = 1$,

$\mu Y = 1$,

and that $\|T\| \leq 1$.

(b) The idea of the argument is that for any $n \geq 1$ we have a positive linear operator $U_n : L^1(\mu^n) \to L^1(\nu^n)$ defined as follows.

If $f_0, \dots, f_{n-1} \in \mathcal{L}^1(\mu)$, set $(f_0 \otimes \dots \otimes f_{n-1})(w) = \prod_{i=0}^n f_i(w(i))$ whenever $w \in \prod_{i<n} \operatorname{dom} f_i$. Now we can define $u_0 \otimes u_1 \otimes \dots \otimes u_{n-1} \in L^1(\mu^n)$, for $u_0, \dots, u_{n-1} \in L^1(\mu)$, by saying that $f_0^\bullet \otimes \dots \otimes f_{n-1}^\bullet = (f_0 \otimes \dots \otimes f_{n-1})^\bullet$ for all $f_0, \dots, f_{n-1} \in \mathcal{L}^1(\mu)$, as in 253E.

Define the operators U_n inductively. $U_1 = T$. Given that $U_n : L^1(\mu^n) \to L^1(\nu^n)$ is a positive linear operator, then we have a bilinear operator $\psi : L^1(\mu^n) \times L^1(\mu) \to L^1(\nu^{n+1})$ defined by saying that $\psi(q,u) = U_n q \otimes Tu$ for $q \in L^1(\mu^n)$, $u \in L^1(\mu)$, where $\otimes : L^1(\nu^n) \times L^1(\nu) \to L^1(\nu^n \times \nu) \cong L^1(\nu^{n+1})$ is the operator of 253E. By 253F, there is a (unique) bounded linear operator $U_{n+1} : L^1(\mu^{n+1}) \to L^1(\nu^{n+1})$ such that $U_{n+1}(q \otimes u) = \psi(q,u)$ for all $q \in L^1(\mu^n)$, $u \in L^1(\mu)$. To see that U_{n+1} is positive, use 253G. (Remember that we are supposing that T is positive.) Continue.

Now it is easy to check that

$$U_n(u_0 \otimes \dots \otimes u_{n-1}) = Tu_0 \otimes \dots \otimes Tu_{n-1}$$

for all $u_0, \dots, u_{n-1} \in L^1(\mu)$. Moreover, $\|U_{n+1}\| \le \|U_n\|\|T\|$ for every n (see 253F), so $\|U_n\| \le 1$ for every n.

For $i < n \in \mathbb{N}$, we have a natural operator $R_{ni} : L^1(\mu) \to L^1(\mu^n)$, defined by saying that $R_{ni} f^\bullet = (f\pi_{ni})^\bullet$ for every $f \in \mathcal{L}^1(\mu)$, where $\pi_{ni}(w) = w(i)$ for $w \in X^n$. Similarly, we have an operator $S_{ni} : L^1(\nu) \to L^1(\nu^n)$. Observe that

$$R_{ni} u = e \otimes \dots \otimes e \otimes u \otimes e \otimes \dots \otimes e$$

where $e = \chi X^\bullet$ and the u is put in the position corresponding to the coordinate i. Since $Te = (\chi Y)^\bullet = e'$ say,

$$U_n R_{ni} u = e' \otimes \dots \otimes Tu \otimes \dots \otimes e' = S_{ni} Tu,$$

for every $u \in L^1(\mu)$.

(c) Let $B \subseteq \mathcal{L}^\infty(\mathrm{T})$ be a countable $\|\,\|_\infty$-bounded set such that $T[Q] = \{g^\bullet : g \in B\}$. ($T[Q]$ is $\|\,\|_\infty$-bounded because T is positive and $T(\chi X)^\bullet = (\chi Y)^\bullet$.) I seek to show that B is stable by using the criterion 465M(v). Let $\epsilon > 0$. Then there is an $m \ge 1$ such that $\int f_{kl}(w)\mu^{\mathbb{N}}(dw) \le \epsilon$ for any $k, l \ge m$, writing

$$f_{kl}(w) = \sup_{f \in A} |\tfrac{1}{k}\textstyle\sum_{i=0}^{k-1} f(w(i)) - \tfrac{1}{l}\sum_{i=0}^{l-1} f(w(i))|$$

for $w \in X^{\mathbb{N}}$; note that f_{kl} is measurable because A is countable.

Take any $k, l \ge m$ and consider

$$g_{kl}(z) = \sup_{g \in B} |\tfrac{1}{k}\textstyle\sum_{i=0}^{k-1} g(z(i)) - \tfrac{1}{l}\sum_{i=0}^{l-1} g(z(i))|$$

for $z \in Y^{\mathbb{N}}$. I claim that $\int g_{kl} d\nu^{\mathbb{N}} \le \epsilon$. **P** Set $n = \max(k,l)$. Then $\int g_{kl} d\nu^{\mathbb{N}} = \int \tilde{g}\, d\nu^n$, where

$$\tilde{g}(z) = \sup_{g \in B} |\tfrac{1}{k}\textstyle\sum_{i=0}^{k-1} g(z(i)) - \tfrac{1}{l}\sum_{i=0}^{l-1} g(z(i))|$$

for $z \in Y^n$. If we look at $\tilde{g}^\bullet$ in $L^1(\nu^n)$, we see that it is

$$\sup_{g \in B} |\tfrac{1}{k}\textstyle\sum_{i=0}^{k-1} S_{ni} g^\bullet - \tfrac{1}{l}\sum_{i=0}^{l-1} S_{ni} g^\bullet|$$

where $S_{ni} : L^1(\nu) \to L^1(\nu^n)$ is defined in (b) above. Thus

$$\tilde{g}^\bullet = \sup_{v \in T[Q]} |\tfrac{1}{k}\textstyle\sum_{i=0}^{k-1} S_{ni} v - \tfrac{1}{l}\sum_{i=0}^{l-1} S_{ni} v|.$$

Similarly, setting

$$\tilde{f}(w) = \sup_{f \in A} |\tfrac{1}{k}\textstyle\sum_{i=0}^{k-1} f(w(i)) - \tfrac{1}{l}\sum_{i=0}^{l-1} f(w(i))|$$

for $w \in X^n$,

$$\tilde{f}^\bullet = \sup_{u \in Q} |\tfrac{1}{k}\textstyle\sum_{i=0}^{k-1} R_{ni} u - \tfrac{1}{l}\sum_{i=0}^{l-1} R_{ni} u|.$$

Now consider $U_n \tilde{f}^\bullet$. For any $v \in T[Q]$, we can express v as Tu where $u \in Q$, so

$$\begin{aligned}|\frac{1}{k}\sum_{i=0}^{k-1} S_{ni}v - \frac{1}{l}\sum_{i=0}^{l-1} S_{ni}v| &= |\frac{1}{k}\sum_{i=0}^{k-1} S_{ni}Tu - \frac{1}{l}\sum_{i=0}^{l-1} S_{ni}Tu| \\ &= |\frac{1}{k}\sum_{i=0}^{k-1} U_nR_{ni}u - \frac{1}{l}\sum_{i=0}^{l-1} U_nR_{ni}u|\end{aligned}$$

(because $U_nR_{ni} = S_{ni}T$, as noted in (b) above)

$$\begin{aligned}&= |U_n(\frac{1}{k}\sum_{i=0}^{k-1} R_{ni}u - \frac{1}{l}\sum_{i=0}^{l-1} R_{ni}u)| \\ &\leq U_n(|\frac{1}{k}\sum_{i=0}^{k-1} R_{ni}u - \frac{1}{l}\sum_{i=0}^{l-1} R_{ni}u|)\end{aligned}$$

(because U_n is positive)

$$\leq U_n\tilde{f}^\bullet.$$

As v is arbitrary, $\tilde{g}^\bullet \leq U_n\tilde{f}^\bullet$, and

$$\int g_{kl}d\nu^{\mathbb{N}} = \int \tilde{g}\,d\nu^n = \|\tilde{g}^\bullet\|_1 \leq \|U_n\tilde{f}^\bullet\|_1 \leq \|\tilde{f}^\bullet\|_1$$

(because $\|U_n\| \leq 1$)

$$\leq \epsilon$$

because k, $l \geq m$. **Q**

(d) As ϵ is arbitrary, B satisfies the criterion 465M(v), and is stable. So $T[Q]$ is stable, by 465Pa in the other direction.

(e) Now let us seek to unwind the list of special assumptions used in the argument above. Suppose we drop the last two, and assume only that

$(\mathfrak{A}, \bar{\mu})$ and $(\mathfrak{B}, \bar{\nu})$ are the measure algebras of measure spaces (X, Σ, μ) and (Y, T, ν),
Q is countable,
T is positive,
μ and ν are totally finite,
$T(\chi X^\bullet) = \chi Y^\bullet$,
$Q \subseteq L^\infty(\mathfrak{A})$ is $\|\,\|_\infty$-bounded,
$\nu Y = 1$.

Then $T[Q]$ is stable. **P** Define $\mu_1 : \Sigma \to [0, \infty[$ by setting $\mu_1 E = \int T(\chi E^\bullet)$ for every $E \in \Sigma$. Then μ_1 is countably additive because T is (sequentially) order-continuous (355Ka). If $\mu E = 0$ then $\chi E^\bullet = 0$ in $L^1(\mu)$ and $\mu_1 E = 0$, so μ_1 is truly continuous with respect to μ (232Bb) and has a Radon-Nikodým derivative (232E). By 465Ck, A is stable with respect to μ_1, while $\mu_1 X = \nu Y = 1$, because $T(\chi X)^\bullet = \chi Y^\bullet$.

Let $(\mathfrak{A}_1, \bar{\mu}_1)$ be the measure algebra of μ_1. If $E \in \Sigma$ and $\mu_1 E = 0$, then $T(\chi E^\bullet) = 0$. Accordingly we can define an additive function $\theta : \mathfrak{A}_1 \to L^1(\nu)$ by setting $\theta E^\bullet = T(\chi E^\bullet)$ for every $E \in \Sigma$. (Note that the two $^\bullet$s here must be interpreted differently. In the formula $\theta E^\bullet$, the equivalence class $E^\bullet$ is to be taken in $\mathfrak{A}_1$. In the formula $\chi E^\bullet = (\chi E)^\bullet$, the equivalence class is to be taken in $L^0(\mu)$. In the rest of this proof I will pass over such points without comment; I hope the context will always make it clear how each $^\bullet$ is to be read.) Because T is positive, θ is non-negative, and by the definition of μ_1 we have $\|\theta a\|_1 = \bar{\mu}_1 a$ for every $a \in \mathfrak{A}_1$. So we have a positive linear operator $T_1 : L^1(\mathfrak{A}_1, \bar{\mu}_1) \to L^1(\nu)$ defined by setting

$$T_1(\chi E^\bullet) = \theta E^\bullet = T(\chi E^\bullet)$$

for every $E \in \Sigma$ (365I).

If $f : X \to \mathbb{R}$ is simple (that is, a linear combination of characteristic functions of sets in Σ), then $T_1 f^\bullet = Tf^\bullet$. So this is also true for every $f \in \mathcal{L}^\infty(\Sigma)$; in particular, it is true for every $f \in A$, so that

$T[Q] = T_1[Q_1]$, where $Q_1 = \{f^\bullet : f \in A\} \subseteq L^1(\mu_1)$. But μ_1, Q_1 and T_1 satisfy all the conditions of (a), so (b)-(d) tell us that $T_1[Q_1]$ is stable, and $T[Q]$ is stable, as required. **Q**

(f) The next step is to drop the condition '$\nu Y = 1$'. But this is elementary, since we are still assuming that ν is totally finite, and multiplying ν by a non-zero scalar doesn't change $L^0(\nu)$ or the stability of any of its subsets, while the case $\nu Y = 0$ is trivial. So we conclude that if

$(\mathfrak{A}, \bar{\mu})$ and $(\mathfrak{B}, \bar{\nu})$ are the measure algebras of measure spaces (X, Σ, μ) and (Y, T, ν),
Q is countable,
T is positive,
μ and ν are totally finite,
$T(\chi X^\bullet) = \chi Y^\bullet$,
$Q \subseteq L^\infty(\mathfrak{A})$ is $\| \|_\infty$-bounded,

then $T[Q]$ is stable.

(g) We can now attack what remains. We find that if

$(\mathfrak{A}, \bar{\mu})$ and $(\mathfrak{B}, \bar{\nu})$ are the measure algebras of measure spaces (X, Σ, μ) and (Y, T, ν),
Q is countable,
T is positive,

then $T[Q]$ is stable. **P** At this point recall that we are supposing that Q is order-bounded. Let $u_0 \in L^1(\mu)$ be such that $|u| \leq u_0$ for every $u \in Q$; let $f_0 \in \mathcal{L}^0(\Sigma)^+$ be such that $f_0^\bullet = u_0$. Setting $A' = \{(f \wedge f_0) \vee (-f_0) : f \in A\}$, A' is still stable, because its image in $L^1(\mu)$ is still Q, or otherwise. Set $v_0 = Tu_0$, and let $g_0 \in \mathcal{L}^0(\mathrm{T})^+$ be such that $g_0^\bullet = v_0$. Because T is positive, $|Tu| \leq T|u| \leq v_0$ for every $u \in Q$. So we can represent $T[Q]$ as $\{g^\bullet : g \in B\}$, where $B \subseteq \mathcal{L}^0(\mathrm{T})$ is a countable set and $|g| \leq g_0$ for every $g \in B$. Set $F_0 = \{y : g_0(y) \neq 0\}$.

Define measures μ_1, ν_1 by setting $\mu_1 E = \int_E f_0 d\mu$ for $E \in \Sigma$, $\nu_1 F = \int_F g_0 d\nu$ for $F \in \mathrm{T}$. Then both μ_1 and ν_1 are totally finite. By 465Ck, A' is stable with respect to μ_1. Set $A_1 = \{\frac{f}{f_0} : f \in A'\}$, interpreting $\frac{f}{f_0}(x)$ as 0 if $f_0(x) = 0$; then A_1 is stable with respect to μ_1, by 465Ci, and $\|f\|_\infty \leq 1$ for every $f \in A_1$. Take $Q_1 = \{f^\bullet : f \in A_1\} \subseteq L^1(\mu_1)$, so that Q_1 is stable.

We have a norm-preserving positive linear operator $R : L^1(\mu_1) \to L^1(\mu)$ defined by setting $Rf^\bullet = (f \times f_0)^\bullet$ for every $f \in \mathcal{L}^1(\mu_1)$ (use 235A). Observe that $R[Q_1] = Q$ and $R(\chi X)^\bullet = u_0$. Similarly, we have a norm-preserving positive linear operator $S : L^1(\nu_1) \to L^1(\nu)$ defined by setting $Sg^\bullet = (g \times g_0)^\bullet$ for $g \in \mathcal{L}^1(\nu_1)$. The set of values of S is just

$$\{g^\bullet : g \in \mathcal{L}^1(\nu),\ g(y) = 0 \text{ whenever } g_0(y) = 0\},$$

which is the band of $L^1(\nu)$ generated by v_0. So

$$\{u : u \in L^1(\mu_1),\ TR|u| \in S[L^1(\nu_1)]\}$$

is a band in $L^1(\nu_1)$ containing $\chi X^\bullet$, and must be the whole of $L^1(\mu_1)$. Thus we have a positive linear operator $T_1 = S^{-1}TR : L^1(\mu_1) \to L^1(\nu_1)$, and $T_1(\chi X)^\bullet = \chi Y^\bullet$ in $L^1(\nu_1)$.

By (f), $T_1[Q_1]$ is stable in $L^1(\nu_1)$. Observe that $T_1[Q_1] = \{S^{-1}g^\bullet : g \in B\} = \{g^\bullet : g \in B_1\}$, where $B_1 = \{\frac{g}{g_0} : g \in B\}$, interpreting $\frac{g}{g_0}(y)$ as 0 if $y \in Y \setminus F_0$. Consequently B_1 and $B = \{g \times g_0 : g \in B_1\}$ are stable with respect to ν_1. By 465Ck, once more, B_1 is stable in $L^1(\nu_0)$, where

$$\nu_0 F = \int_F \frac{1}{g_0} d\nu_1 = \nu(F \cap F_0)$$

for any $F \in \mathrm{T}$. But because $g(y) = 0$ whenever $g \in B$ and $y \in Y \setminus F_0$,

$$(\nu^{2k})^* D_k(B, F, \alpha, \beta) = (\nu^{2k})^* D_k(B, F \cap F_0, \alpha, \beta) = (\nu_0^{2k})^* D_k(B, F, \alpha, \beta)$$

whenever $F \in \mathrm{T}$, $\alpha < \beta$ and $k \geq 1$; so B is also stable with respect to ν, and $Q = \{g^\bullet : g \in B\}$ is stable in $L^1(\nu)$. **Q**

(h) The worst is over. If we are not told that T is positive, we know that it is expressible as the difference of positive linear operators T_1 and T_2 (371D); now $T_1[Q]$ and $T_2[Q]$ will be stable, by the work above, so $T[Q] \subseteq T_1[Q] - T_2[Q]$ is stable, by 465Nb. If we are not told that Q is countable, we refer to 465P to see that we need only check that countable subsets of $T[Q]$ are stable, and these are images of countable subsets of

Q. Finally, the identification of the abstract measure algebras $(\mathfrak{A}, \bar{\mu}_1)$ and $(\mathfrak{B}, \bar{\nu}_1)$ with the measure algebras of measure spaces is Theorem 321J.

***465S R-stable sets** The theory above has been developed in the context of general measure (or probability) spaces and the 'ordinary' product measure of measure spaces. For τ-additive measures – in particular, for Radon measures – we have an alternative product measure, as described in §417. If $(X, \mathfrak{T}, \Sigma, \mu)$ is a semi-finite τ-additive topological measure space such that μ is inner regular with respect to the Borel sets, write $\tilde{\mu}^I$ for the τ-additive product measure on X^I, as described in 417D (for the product of two spaces) and 417F (for the product of any family of probability spaces); just as in 251W, we can extend the construction of 417D to arbitrary finite products. Now say that $A \subseteq \mathbb{R}^X$ is **R-stable** if whenever $0 < \mu E < \infty$ and $\alpha < \beta$ there is a $k \geq 1$ such that $(\tilde{\mu}^{2k})^* D_k(A, E, \alpha, \beta) < (\mu E)^{2k}$. Because we have a version of Fubini's theorem for the products of τ-additive topological measures (417H), all the arguments of this section can be applied to R-stable sets, yielding criteria for R-stability exactly like those in 465M.

Because the τ-additive product measure extends the c.l.d. product measure, stable sets are always R-stable. (We must have

$$(\tilde{\mu}^{2k})^* D_k(A, E, \alpha, \beta) \leq (\mu^{2k})^* D_k(A, E, \alpha, \beta)$$

for all k, A, E, α and β.) For an example of an R-stable set which is not stable, see 465U.

The concept of 'R-stability' is used in Talagrand 84 in applications to the integration of vector-valued functions. I give one result, however, to show how it is relevant to a question with a natural expression in the language of this chapter.

***465T Proposition** (Talagrand 84) Let $(X, \mathfrak{T}, \Sigma, \mu)$ be a semi-finite τ-additive topological measure space such that μ is inner regular with respect to the Borel sets. If $A \subseteq C(X)$ is such that every countable subset of A is R-stable, then A is R-stable.

proof For any $\alpha < \beta$ and $k \geq 1$,

$$G_k(A, X, \alpha, \beta) = \bigcup_{f \in A} \{w : w \in X^{2k}, f(w(2i)) < \alpha, \\ f(w(2i+1)) > \beta \text{ for } i < k\}$$

is open. Suppose that $0 < \mu E < \infty$. Because all the product measures $\tilde{\mu}^{2k}$ are τ-additive, we can find a countable set $A' \subseteq A$ such that

$$\tilde{\mu}^{2k} G_k(A, E, \alpha, \beta) = \tilde{\mu}^{2k} G_k(A', E, \alpha, \beta)$$

for every $k \geq 1$ and all rational α, β. Now, if $\alpha < \beta$, there are rational α', β' such that $\alpha < \alpha' < \beta' < \beta$, and a $k \geq 1$ such that $\tilde{\mu}^{2k} D_k(A', E, \alpha', \beta') < (\mu E)^{2k}$; in which case

$$\begin{aligned}(\tilde{\mu}^{2k})^* D_k(A, E, \alpha, \beta) &\leq \tilde{\mu}^{2k} G_k(A, E, \alpha', \beta') = \tilde{\mu}^{2k} G_k(A', E, \alpha', \beta') \\ &\leq \tilde{\mu}^{2k} D_k(A', E, \alpha', \beta') < (\mu E)^{2k}.\end{aligned}$$

As E, α and β are arbitrary, A is R-stable.

***465U** I come now to the promised example of an R-stable set which is not stable. I follow the construction in Talagrand 88, which displays an interesting characteristic related to 465O-465P above.

Example There is a Radon probability space with an R-stable set of continuous functions which is not stable.

proof (a) Let (X, Σ, μ) be an atomless probability space (e.g., the unit interval with Lebesgue measure). Define $\langle r_n \rangle_{n \in \mathbb{N}}$ by setting $r_0 = 1$, $r_1 = 2$, $r_{n+1} = 2^{nr_n}$ for $n \geq 1$; then $2^n \leq r_n < r_{n+1}$ for every n. Let $\langle \Sigma_n \rangle_{n \in \mathbb{N}}$ be an increasing sequence of finite subalgebras of Σ, each Σ_n having r_n atoms of the same size; this is possible because r_{n+1} is always a multiple of r_n. Write $\mathcal{H}_n$ for the set of atoms of Σ_n. Next, for each $n \in \mathbb{N}$, let $\langle G_H \rangle_{H \in \mathcal{H}_n}$ be an independent family in Σ_{n+1} of sets of measure 2^{-n}; such a family exists because r_{n+1} is a multiple of 2^{nr_n}.

Let $\mathcal{E}$ be the family of all sets expressible in the form $E = \bigcup_{i\in\mathbb{N}} H_i$ where, for some strictly increasing sequence $\langle n_i\rangle_{i\in\mathbb{N}}$ in $\mathbb{N}$, $H_i \in \mathcal{H}_{n_i}$ and $H_j \subseteq G_{H_i}$ whenever $i < j$ in $\mathbb{N}$. Set $A = \{\chi E : E \in \mathcal{E}\} \subseteq \mathfrak{L}^0(\Sigma)$.

(b) A is stable. **P** Suppose that $F \in \Sigma$ and that $\mu F > 0$. Take $n \in \mathbb{N}$ so large that $3\cdot 2^{-n} < (\mu F)^2$. Set $\mathcal{H} = \{H : H \in \mathcal{H}_n, \mu(H\cap F) > 0\}$; enumerate $\mathcal{H}$ as $\langle H_i\rangle_{i<m}$; set $F_1 = F\cap\bigcup_{i<m} H_i$, $V = \prod_{j<m}(H_j\cap F_1) \subseteq F_1^m$. Because $\mu F_1 = \mu F$, $m \geq r_n\mu F \geq 3$.

Consider

$$U_k = \bigcup_{H\in\mathcal{H}_k}(H\times H)\cup(H\times G_H)\cup(G_H\times H) \subseteq X^2$$

for $k \in \mathbb{N}$. Then

$$\mu^2 U_k \leq r_k(\tfrac{1}{r_k^2} + \tfrac{1}{2^k r_k} + \tfrac{1}{2^k r_k}) \leq 3\cdot 2^{-k},$$

so

$$\mu^2(F_1^2 \setminus \bigcup_{k>n} U_k) \geq (\mu F)^2 - 3\textstyle\sum_{k=n+1}^{\infty} 2^{-k} > 0.$$

Set

$$V = \{w : w \in F_1^{2m},\ w(2i) \in H_i \text{ for every } i < m,\ (w(1), w(3)) \notin \textstyle\bigcup_{k>n} U_k\}.$$

Then

$$\mu^{2m}(V) \geq \textstyle\prod_{i=0}^{m-1} \mu(F_1\cap H_i)\cdot\mu^2(F_1^2\setminus\bigcup_{k>n}U_k)\cdot(\mu F)^{m-2} > 0.$$

? Suppose, if possible, that there is a point $w \in V \cap D_m(A, F, 0, 1)$. Then there is an $E \in \mathcal{E}$ such that $w(2i) \notin E$, $w(2i+1) \in E$ for $i < m$. Express E as $\bigcup_{j\in\mathbb{N}} E_j$ where $E_j \in \mathcal{H}_{n_j}$ for every $j \in \mathbb{N}$, where $\langle n_j\rangle_{j\in\mathbb{N}}$ is strictly increasing, and $E_k \subseteq G_{E_j}$ whenever $j < k$. Because $w(2i) \in F_1\cap H_i \setminus E$, E_j cannot include H_i for any $i < m$, $j \in \mathbb{N}$; so $E_j \cap H_i = \emptyset$ whenever $i < m$ and $n_j \leq n$. Because $w(1)$, $w(3) \in E$, there are j_0, $j_1 \in \mathbb{N}$ such that $w(1) \in E_{j_0}$ and $w(3) \in E_{j_1}$. Since both $w(1)$ and $w(3)$ belong to $F_1 \subseteq \bigcup_{i<m} H_i$, n_{j_0} and n_{j_1} are both greater than n. But now

— if $j_0 = j_1$, then $(w(1), w(3)) \in E_{j_0}^2$,

— if $j_0 < j_1$, then $(w(1), w(3)) \in E_{j_0}\times E_{j_1} \subseteq E_{j_0}\times G_{E_{j_0}}$,

— if $j_1 < j_0$, then $(w(1), w(3)) \in E_{j_0}\times E_{j_1} \subseteq G_{E_{j_1}}\times E_{j_1}$,

so in any case $(w(1), w(3)) \in U_k$ where $k = \min(j_0, j_1) > n$, which is impossible. **X**

Thus $D_m(A, F, 0, 1)$ does not meet V, and $(\mu^{2m})^* D_m(A, F, 0, 1) < (\mu F)^{2m}$.

Now if $\alpha < \beta$, then $D_m(A, F, \alpha, \beta) = D_m(A, F, 0, 1)$ if $0 \leq \alpha < \beta \leq 1$, $\emptyset$ otherwise; so in all cases $(\mu^{2m})^* D_m(A, F, \alpha, \beta) < (\mu F)^{2m}$. As F also is arbitrary, A is stable, as claimed. **Q**

(c) Now let $(Z, \mathfrak{S}, \mathrm{T}, \nu)$ be the Stone space of the measure algebra of (X, Σ, μ) (321K), so that ν is a Radon measure (411Pe). For $E \in \Sigma$, write E^* for the corresponding open-and-closed set in Z, so that $E \mapsto E^* : \Sigma \to \mathrm{T}$ is a measure-preserving Boolean homomorphism. Set $A^* = \{\chi E^* : E \in \mathcal{E}\} \subseteq C(Z)$. Write ν^m for the c.l.d. product measure on Z^m for $m \geq 1$. We already know that ν^2 is not a topological measure (419Xc).

(d) The point is that $(\nu^{2m})^* D_m(A^*, Z, 0, 1) = 1$ for every $m \geq 1$. **P?** Suppose, if possible, otherwise. Then there is a set $\tilde{W} \subseteq Z^{2m}$ such that $\nu^{2m}(\tilde{W}) > 0$ and $\tilde{W} \cap D_m(A^*, Z, 0, 1) > 0$. For u, $v \in Z^m$, write $u\#v = (u(0), v(0), u(1), v(1), \dots, u(m-1), v(m-1)) \in Z^{2m}$. Then there is an $\epsilon > 0$ such that

$$\tilde{V} = \{v : v \in Z^m,\ \nu^m\{u : u \in Z^m,\ u\#v \in \tilde{W}\} \text{ is defined and greater than } m\epsilon\}$$

has non-zero inner measure for ν^m. Now there are sets $\tilde{F}_{ij} \in \mathrm{T}$, for $i \in \mathbb{N}$ and $j < m$, such that

$$Z^m \setminus \tilde{V} \subseteq \textstyle\bigcup_{i\in\mathbb{N}} \prod_{j<m} \tilde{F}_{ij}, \quad \sum_{i=0}^{\infty}\prod_{j=0}^{m} \nu\tilde{F}_{ij} < 1.$$

Enlarging the $\tilde{F}_{ij}$ slightly if need be, we may suppose that they are all open-and-closed (322Qc), therefore expressible as F_{ij}^* where $F_{ij} \in \Sigma$ for $i \in \mathbb{N}$, $j < m$. Set $V = X^m \setminus \bigcup_{i\in\mathbb{N}} \prod_{j<m} F_{ij}$, so that

$$\mu^m V = \nu^m(Z^m \setminus \textstyle\bigcup_{i\in\mathbb{N}} \prod_{j<m} F_{ij}^*) > 0.$$

I seek to choose $\langle n_k\rangle_{k\in\mathbb{N}}$ in $\mathbb{N}$, $\langle H_k\rangle_{k\in\mathbb{N}}$ and $\langle E_{kj}\rangle_{k\in\mathbb{N}, j<m}$ in Σ inductively, in such a way that

$$2^{-n_0} \leq \tfrac{1}{2}\epsilon,$$

$$E_{kj} \subseteq E_{ij} \cap G_{H_i} \text{ for } i < k,\ j < m,$$

$$\prod_{j<m} E_{kj} \cap \prod_{j<m} F_{kj} = \emptyset,$$

$$\mu^m(V \cap G^m_{H_k} \cap \prod_{j<m} E_{kj}) > 0,$$

$$n_i < n_k \text{ for every } i < k,$$

$$H_k \in \mathcal{H}_{n_k},$$

$$\text{if } k = i_k m + j_k, \text{ where } i_k \in \mathbb{N},\ j_k < m, \text{ then } \mu(H_k \cap E_{kj_k}) > 0,$$

for every $k \in \mathbb{N}$. The induction proceeds as follows. Set $E'_{kj} = X$ if $k = 0$, $G_{H_{k-1}} \cap E_{k-1,j}$ otherwise, so that $\mu(V \cap \prod_{j<m} E'_{kj}) > 0$. Because $V \cap \prod_{j<m} F_{kj}$ is empty, we can find $E_{kj} \subseteq E'_{kj}$, for $j < m$, such that $\mu^m(V \cap \prod_{j<m} E_{kj}) > 0$ and $\prod_{j<m} E_{kj} \cap \prod_{j<m} F_{kj} = \emptyset$. Set $\eta = \mu E_{kj_k}$, $\delta = \mu^m(V \cap \prod_{j<m} E_{kj})$, so that η and δ are both strictly positive.

Now take n_k so large that

$$(\text{if } k = 0)\ 2^{-n_k} \leq \tfrac{1}{2}\epsilon, \quad n_k > n_i \text{ for } i < k, \quad (1 - 2^{-mn_k})^{\eta r_{n_k}} < \delta.$$

(This is possible because $\lim_{n\to\infty} 2^{-mn} r_n = \infty$.) Set $\mathcal{H} = \{H : H \in \mathcal{H}_{n_k}, \mu(H \cap E_{kj_k}) > 0\}$; then $\#(\mathcal{H}) \geq \eta r_{n_k}$. Consider the family $\langle G^m_H \rangle_{H\in\mathcal{H}}$. These are stochastically independent sets of measure 2^{-mn_k}, so their union has measure $1 - (1 - 2^{-mn_k})^{\#(\mathcal{H})} > 1 - \delta$, and there is an $H_k \in \mathcal{H}$ such that $\mu^m(V \cap G^m_{H_k} \cap \prod_{j<m} E_{kj}) > 0$. Thus the induction continues.

Look at the sequence $\langle H_k \rangle_{k\in\mathbb{N}}$ and its union E. We have $H_k \in \mathcal{H}_{n_k}$ for every k; moreover, if $i < k$, then $\mu(H_k \cap E_{kj_k}) > 0$, while $E_{kj_k} \subseteq G_{H_i}$; since H_k is an atom of Σ_{n_k}, while $G_{H_i} \in \Sigma_{n_k}$, $H_k \subseteq G_{H_i}$. Thus $E \in \mathcal{E}$. Next, whenever $i \leq k \in \mathbb{N}$,

$$\prod_{j<m} E_{kj} \cap \prod_{j<m} F_{ij} \subseteq \prod_{j<m} E_{ij} \cap \prod_{j<m} F_{ij} = \emptyset,$$

so $\prod_{j<m} E_{kj} \cap \bigcup_{i\leq k} \prod_{j<m} F_{ij} = \emptyset$. At the same time, we know that

$$E^m \cap \prod_{j<m} E_{kj} \supseteq \prod_{j<m} H_{km+j} \cap E_{kj} \supseteq \prod_{j<m} H_{km+j} \cap E_{km+j,j}$$

has non-zero measure. So $\mu^m(E^m \setminus \bigcup_{i\leq k} \prod_{j<m} F_{ij}) > 0$.

Moving back to Z, this translates into

$$\nu^m((E^*)^m \setminus \bigcup_{i\leq k} \prod_{j<m} F^*_{ij}) > 0.$$

But this means that $(E^*)^m$ is not included in $\bigcup_{i\leq k} \prod_{j<m} F^*_{ij}$, for any $k \in \mathbb{N}$. Because E^* is compact and every F^*_{ij} is open, $(E^*)^m$ is not included in $\bigcup_{i\in\mathbb{N}} \prod_{j<m} F^*_{ij}$, and there is some $v \in (E^*)^m \cap \tilde{V}$.

By the definition of $\tilde{V}$,

$$\begin{aligned}\nu^m\{u : u\#v \in \tilde{W}\} > m\epsilon &\geq m\sum_{k=0}^{\infty} 2^{-n_0-k} \geq m\sum_{k=0}^{\infty} 2^{-n_k} \\ &= m\sum_{k=0}^{\infty} \mu H_k \geq m\mu E = m\nu E^*.\end{aligned}$$

So there must be some u such that $u\#v \in \tilde{W}$ and $u(j) \notin E^*$ for every $j < m$. But now, setting $w = u\#v$, we have $w(2j) \notin E^*$, $w(2j+1) \in E^*$ for $j < m$, and $w \in D_m(A^*, Z, 0, 1) \cap \tilde{W}$; which is supposed to be impossible. **XQ**

(e) This shows that A^* is not stable. It is, however, R-stable. **P** We have a measure algebra isomorphism between the measure algebras of μ and ν defined by the map $E \mapsto E^* : \Sigma \to \mathrm{T}$. The corresponding isomorphism between $L^0(\mu)$ and $L^0(\nu)$ takes $\{f^\bullet : f \in A\}$ to $\{h^\bullet : h \in A^*\}$. By 465Pa and (b) above, $\{f^\bullet : f \in A\}$ is stable in $L^0(\mu)$, so $\{h^\bullet : h \in A^*\}$ is stable in $L^0(\nu)$, and every countable subset of A^* is stable. Since $A^* \subseteq C(X)$, it follows that A^* is stable (465T). **Q**

***465V Remark** This example is clearly related to 419E. The argument here is significantly deeper, but it does have an idea in common with that in 419E, besides the obvious point that both involve the Stone spaces of atomless probability spaces. Suppose that, in the context of 465U, we take $\mathcal{E}_0$ to be the family of sets E expressible as the union of a *finite* chain $H_0, \dots, H_k$ where $H_i \in \mathcal{H}_{n_i}$ for $i \leq k$ and $H_j \subseteq G_{H_i}$ for $i < j \leq k$. Then we find, on repeating the argument of (b) in the proof of 465U, that the countable set $A_0^* = \{\chi E^* : E \in \mathcal{E}_0\}$ is stable, so that, setting $W_m = D_m(A_0^*, Z, 0, 1)$, $\nu^{2m}W_m$ is small for large m. On the other hand, setting

$$\tilde{W}_m = \bigcup\{V : V \subseteq Z^m \text{ is open, } V \setminus W_m \text{ is negligible}\},$$

we see that $D_m(A^*, Z, 0, 1) \subseteq \tilde{W}_m$, so that $(\nu^{2m})^*\tilde{W}_m = 1$ for all $m \geq 1$. Of course, writing $\tilde{\nu}^{2m}$ for the Radon product measure on Z^{2m}, we have $\tilde{\nu}^{2m}(\tilde{W}_m) = \nu^{2m}W_m < 1$ for large m, just as in 419E.

Both $A \subseteq \mathcal{L}^0(\Sigma)$ and $A^* \subseteq \mathcal{L}^0(\mathrm{T})$ are relatively pointwise compact. Note that while I took (X, Σ, μ) and (Z, T, ν) to be quite separate, it is entirely possible for them to be actually the same space. In this case it is natural to take every Σ_n to consist of open-and-closed sets, so that every member of $\mathcal{E}$ is open, and E^* becomes identified with the closure of E for $E \in \mathcal{E}$.

465X Basic exercises (a) Let (X, Σ, μ) be a measure space, and $\langle f_n \rangle_{n\in\mathbb{N}}$ a sequence of measurable real-valued functions on X which converges a.e. Show that $\{f_n : n \in \mathbb{N}\}$ is stable.

(b) Let $\mathcal{C}$ be the family of convex sets in $\mathbb{R}^r$. Show that $\{\chi C : C \in \mathcal{C}\}$ is stable with respect to Lebesgue measure on $\mathbb{R}^r$, but that if $r \geq 2$ there is a Radon probability measure ν on $\mathbb{R}^r$ such that $\{\chi C : C \in \mathcal{C}, C \text{ is closed}\}$ is not stable with respect to ν.

(c) Show that, for any $M \geq 0$, the set of functions $f : \mathbb{R} \to \mathbb{R}$ of variation at most M is stable with respect to any Radon measure on $\mathbb{R}$. (*Hint*: show that if μ is a Radon measure on $\mathbb{R}$ and $E \in \operatorname{dom}\mu$ has non-zero finite measure, and $(2k-1)(\beta-\alpha) > M$, then $(\mu^{2k})^* D_k(A, E, \alpha, \beta) < (\mu E)^{2k}$.)

(d) Let (X, Σ, μ) be a measure space, and $A \subseteq \mathbb{R}^X$. Show that A is stable iff $\{f^+ : f \in A\}$ and $\{f^- : f \in A\}$ are both stable.

(e) Let (X, Σ, μ) and (Y, T, ν) be measure spaces, and $\phi : X \to Y$ an inverse-measure-preserving function. Show that if $B \subseteq \mathbb{R}^Y$ is stable with respect to ν, then $\{g\phi : g \in B\}$ is stable with respect to μ.

(f) Let (X, Σ, μ) be a semi-finite measure space and $A \subseteq \mathbb{R}^X$. (i) Suppose that μ is inner regular with respect to the family $\{F : F \in \Sigma, \{f \times \chi F : f \in A\} \text{ is stable}\}$. Show that A is stable. (ii) Use this together with 465Ce, 465Cf and 465Cl to prove 465Ci.

(g) Let (X, Σ, μ) be a totally finite measure space and T a σ-subalgebra of Σ. Let $A \subseteq \mathcal{L}^0(\mathrm{T})$ be any set. (i) Show that if A is $\mu{\restriction}\mathrm{T}$-stable then it is μ-stable. (ii) Give an example to show that A can be μ-stable and pointwise compact without being $\mu{\restriction}\mathrm{T}$-stable. (*Hint*: take μ to be Lebesgue measure on $[0,1]$ and T the countable-cocountable algebra.)

(h) Let (X, Σ, μ) be a measure space, and $A \subseteq \mathbb{R}^X$. For $g : X \to [0, \infty[$ set $A_g = \{(f \wedge g) \vee (-g) : f \in A\}$. Show that A is stable iff A_g is stable for every integrable $g : X \to [0, \infty[$.

(i) Let (X, Σ, μ) be a locally determined measure space and $A \subseteq \mathbb{R}^X$ a stable set. Let $\overline{A}$ be the closure of A for the topology of pointwise convergence. Show that $\{f^\bullet : f \in \overline{A}\}$ is just the closure of $\{f^\bullet : f \in A\} \subseteq L^0(\mu)$ for the topology of convergence in measure.

(j) Show that there is a disjoint family $\mathcal{I}$ of finite subsets of $[0,1]$ such that $A = \{\chi I : I \in \mathcal{I}\}$ is not stable, though A is pointwise compact and the identity map on A is continuous for the topology of pointwise convergence and the topology of convergence in measure.

(k) Let (X, Σ, μ) be a probability space. Show that $A \subseteq \mathbb{R}^X$ is stable iff

$$\inf_{m\in\mathbb{N}}\big((\mu^{2m})^* D_m(A, X, \alpha, \beta)\big)^{1/m} = 0$$

whenever $\alpha < \beta$ in $\mathbb{R}$.

(l) Let (X,Σ,μ) be a measure space. Show that a countable set $A \subseteq \mathcal{L}^0(\Sigma)$ is not stable iff there are $E \in \Sigma$ and $\alpha < \beta$ such that $\mu E > 0$ and $\mu^m \tilde{D}_m(A,E,\alpha,\beta) = (\mu E)^m$ for every $m \geq 1$, where $\tilde{D}_m(A,E,\alpha,\beta)$ is the set of those $w \in E^m$ such that for every $I \subseteq m$ there is an $f \in A$ such that $f(w(i)) \leq \alpha$ for $i \in I$, $f(w(i)) \geq \beta$ for $i \in m \setminus I$. (*Hint*: see part (iii) of case 2 of the proof of 465L.)

(m) Let (X,Σ,μ) be a semi-finite measure space, and $A \subseteq \mathcal{L}^0(\Sigma)$ a set which is compact and metrizable for the topology of pointwise convergence. Show that A is stable. (*Hint*: apply the ideas of case 2 in the proof of 465L to a countable dense subset of A.)

(n) Let (X,Σ,μ) be a probability space and $A \subseteq \mathcal{L}^0(\Sigma)$ a uniformly bounded set of functions. Show that A is stable iff

$$\lim_{n\to\infty} \overline{\int} \sup_{f\in A,k,l\geq n} \left|\frac{1}{k}\sum_{i=0}^{k-1} f(w(i)) - \frac{1}{l}\sum_{i=0}^{l-1} f(w(i))\right| \mu^{\mathbb{N}}(dw) = 0.$$

(o) Show that there is a set $A \subseteq \mathbb{R}^{[0,1]}$ such that $g(x) = \sup_{f\in A} |f(x)|$ is finite for every x, and A is stable with respect to Lebesgue measure, but its convex hull $\Gamma(A)$ is not. (*Hint*: take $A = \{g(x)\chi\{x\} : x \in [0,1]\}$, where g is such that for every $m \geq 1$, every non-negligible compact set $K \subseteq [0,1]^m$ there is a $w \in K$ such that $g(w(i)) = 2^{i+1}$ for every $i < m$.)

(p) Let (X,Σ,μ) be a strictly localizable measure space and $Q \subseteq L^0(\mu)$ a set which is stable in the sense of 465R. Show that the closure of Q (for the topology of convergence in measure) is stable. (*Hint*: 465Xi.)

(q) Let (X,Σ,μ) be a probability space, T a σ-subalgebra of Σ, and $A \subseteq \mathbb{R}^X$ a countable stable set of Σ-measurable functions such that $\int \sup_{f\in A} |f(x)|\mu(dx) < \infty$. Show that if for each $f \in A$ we choose a conditional expectation g_f of f on T (requiring each g_f to be T-measurable and defined everywhere on X), then $\{g_f : f \in A\}$ is stable.

(r) Give an example of a probability algebra $(\mathfrak{A},\bar{\mu})$, a conditional expectation operator $P : L^1_{\bar{\mu}} \to L^1_{\bar{\mu}}$ (365R), and a uniformly integrable stable set $A \subseteq L^1_{\bar{\mu}}$ such that $P[A]$ is not stable. (*Hint*: start by picking a sequence $\langle v_n\rangle_{n\in\mathbb{N}}$ in $P[L^1_{\bar{\mu}}]$ which is norm-convergent to 0 but not stable, and express this as $\langle Pu_n\rangle_{n\in\mathbb{N}}$ where $\bar{\mu}[\![u_n > 0]\!] \leq 2^{-n}$ for every n.)

465Y Further exercises (a) Find an integrable continuous function $f : [0,1[^2 \to [0,\infty[$ such that, in the notation of 465H, $\limsup_{k\to\infty} \int f d\nu^2_{wk} = \infty$ for almost every $w \in [0,1]^{\mathbb{N}}$. (*Hint*: arrange for $f(x,x)$ to grow very fast as $x \uparrow 1$.)

(b) Show that in 465M we may replace the condition 'A is uniformly bounded' by the condition '$|f| \leq f_0$ for every $f \in A$, where f_0 is integrable'. (*Hint*: Talagrand 87.)

(c) Let $(X,\mathfrak{T},\Sigma,\mu)$ be a τ-additive topological measure space such that μ is inner regular with respect to the Borel sets. Show that a countable R-stable subset of $\mathbb{R}^X$ is stable.

(d) Let $(X,\mathfrak{T},\Sigma,\mu)$ be a complete τ-additive topological probability space such that μ is inner regular with respect to the Borel sets, and $A \subseteq [0,1]^X$ an R-stable set. Suppose that $\epsilon > 0$ is such that $\int f d\mu \leq \epsilon^2$ for every $f \in A$. Show that there are an $n \geq 1$ and a Borel set $W \subseteq X^n$ and a $\gamma > \tilde{\mu}^n W$ (writing $\tilde{\mu}^n$ for the τ-additive product measure on X^n) such that $\int f d\nu \leq 3\epsilon$ whenever $f \in A$, $\nu : \mathcal{P}X \to [0,1]$ is a point-supported probability measure and $\nu^n W \leq \gamma$.

465 Notes and comments The definition in 465B arose naturally when M.Talagrand and I were studying pointwise compact sets of measurable functions; we found that in many cases a set of functions was relatively pointwise compact because it was stable (465Db). Only later did it appear that the concept was connected with 'Glivenko-Cantelli' classes in the theory of empirical measures, as explained in Talagrand 87.

It is not the case that all pointwise compact sets of measurable functions are stable. In fact I have already offered examples in 463Xi and 464E above. In both cases it is easy to check from the definition in 465B that they are not stable, as can also be deduced from 465G. Another example is in 465Xj. You will observe

however that all these examples are 'pathological' in the sense that either the measure space is irregular (from some points of view, indeed, any measure space not isomorphic to Lebesgue measure on the unit interval can be dismissed as peripheral), or the set of functions is uninteresting. It is clear from 465R and 465T, for instance, that we should start with countable sets. So it is natural to ask: if we have a *separable* pointwise compact set of real-valued measurable functions on the unit interval, must it be stable? It turns out that this is undecidable in Zermelo-Fraenkel set theory (Shelah & Fremlin 93); I hope to return to the question in Volume 5. (If we ask for 'metrizable', instead of 'separable', we get a positive answer; see 465Xm.)

The curious phrasing of the statement of 465M(iii), with the auxiliary functions h_k, turns on the fact that all the expressions '$\sup_{f\in A}\dots$' here give rise to functions which need not be measurable. Thus the simple pointwise convergence described in (ii) and (iv) is not at all the same thing as the convergence in (v), which may be thought of as a kind of $\|\ \|_1$-convergence if we write $\|g\|_1 = \overline{\int}|g|$ for arbitrary real-valued functions g. (Since the sets A here are uniformly bounded, it may equally be thought of as convergence in measure.) Similarly, 465M(iii) is saying much more than just

$$\lim_{k\to\infty}\sup_{f\in A}\frac{1}{k}\sum_{i=0}^{k-1}\big|f(w(i)) - \mathbb{E}(f|\mathrm{T})(w(i))\big| = 0 \text{ a.e.},$$

though of course for countable sets A these distinctions disappear. On the other hand, since the convergence is certainly not monotonic in k, $\|\ \|_1$-convergence does not imply pointwise convergence. So we can look for something stronger than either (iv) or (v) of 465M, as in 465Xn. But this is still nowhere near the strength of 465M(iii), in which $|\sum\dots|$ is replaced by $\sum|\dots|$. For further variations, see Talagrand 87 and Talagrand 96.

If we wish to adapt the ideas here to spaces of equivalence classes of functions rather than spaces of true functions, we find that problems of measurability evaporate, and that (because the definition of stability looks only at sets of finite measure) all the relevant suprema can be interpreted as suprema of countable sets. Consequently a subset of $L^0(\mu)$ or $L^0(\mathfrak{A})$ is stable if all its countable subsets are stable (465Pa). It is remarkable that, for strictly localizable measures μ, we can lift any stable set in L^0 to a stable set in $\mathcal{L}^0$ (465Pb, 465Q). By moving to function spaces we get a language in which to express a new kind of permanence property of stable sets (465R, 465Xq). See also Talagrand 89.

The definition of 'stable set' of functions seems to be utterly dependent on the underlying measure space. But 465R tells us that in fact the property of being an order-bounded stable subset of $L^1(\bar{\mu})$ is invariant under normed space automorphisms. ('Order-boundedness' is a normed space invariant in L^1 spaces by the Chacon-Krengel theorem, 371D.) Since stability can be defined in terms of order-bounded sets (465Xh), we could, for instance, develop a theory of stable sets in abstract L-spaces.

The theory of stable sets is of course bound intimately to the theory of product measures, and such results as 465J have independent interest as theorems about sets in product spaces. So any new theory of product measures will give rise to a new theory of stable sets. In particular, the τ-additive product measures in §417 lead to R-stable sets (465S). It is instructive to work through the details, observing how the properties of the product are employed. Primarily, of course, we need 'associative' and 'commutative' laws, and Fubini's theorem; but some questions of measurability need to be re-examined, as in 465Yd.

I have starred 465U because it involves the notion of R-stability. In fact this appears only in the final stage, and the construction, as set out in part (a) of the proof, is an instructive challenge to any intuitive concept of what stable sets are like.

466 Measures on linear topological spaces

In this section I collect a number of results on the special properties of topological measures on linear topological spaces. The most important is surely Phillips' theorem (466A-466B): on any Banach space, the weak and norm topologies give rise to the same totally finite Radon measures. This is not because the weak and norm topologies have the same Borel σ-algebras, though this does happen in interesting cases (466C-466E, §467). When the Borel σ-algebras are different, we can still ask whether the Borel measures are 'essentially' the same, that is, whether every (totally finite) Borel measure for the weak topology extends to a Borel measure for the norm topology. A construction due to M.Talagrand (466H) gives a negative answer.

Just as in $\mathbb{R}^r$, a totally finite quasi-Radon measure on a locally convex linear topological space is determined by its characteristic function (466K). I end the section with a note on measurability conditions sufficient to ensure that a linear operator between Banach spaces is continuous (466L-466M).

466A Theorem Let $(X, \mathfrak{T})$ be a metrizable locally convex linear topological space and μ a σ-finite measure on X which is quasi-Radon for the weak topology $\mathfrak{T}_s(X, X^*)$. Then the support of μ is separable, so μ is quasi-Radon for the original topology $\mathfrak{T}$. If X is complete and μ is locally finite with respect to $\mathfrak{T}$, then μ is Radon for $\mathfrak{T}$.

proof (a) Let $\langle V_n\rangle_{n\in\mathbb{N}}$ be a sequence running over a base of neighbourhoods of 0 in X, and for $n \in \mathbb{N}$ set $V_n^\circ = \{f : f \in X^*, |f(x)| \leq 1 \text{ for every } x \in V_n\}$. Then each V_n° is a convex $\mathfrak{T}_s$-compact subset of X^* (4A4Bh), and $X^* = \bigcup_{n\in\mathbb{N}} V_n^\circ$. Let $Z \subseteq X$ be the support of μ, and for $n \in \mathbb{N}$ set $K_n = \{f\restriction Z : f \in V_n^\circ\}$. Since the map $f \mapsto f\restriction Z : X^* \to C(Z)$ is linear and continuous for $\mathfrak{T}_s$ and the topology $\mathfrak{T}_p$ of pointwise convergence on Z, each K_n is convex and $\mathfrak{T}_p$-compact. Next, the subspace measure μ_Z on Z is σ-finite and strictly positive, so by 463E each K_n is $\mathfrak{T}_p$-metrizable.

Let $\mathcal{U}$ be the base for $\mathfrak{T}_p$ consisting of sets of the form

$$U(I, h, \epsilon) = \{f : f \in C(Z), |f(x) - h(x)| < \epsilon \text{ for every } x \in I\},$$

where $I \subseteq Z$ is finite, $h \in \mathbb{R}^I$ and $\epsilon > 0$. For each $n \in \mathbb{N}$, write $\mathcal{V}_n = \{K_n \cap U : U \in \mathcal{U}\}$, so that $\mathcal{V}_n$ is a base for the subspace topology of K_n (4A2B(a-iv)). Since this is compact and metrizable, therefore second-countable, there is a countable base $\mathcal{V}_n' \subseteq \mathcal{V}_n$ (4A2Ob). Now there is a countable set $\mathcal{U}' \subseteq \mathcal{U}$ such that $\mathcal{V}_n' \subseteq \{K_n \cap U : U \in \mathcal{U}'\}$ for every $n \in \mathbb{N}$, and a countable set $D \subseteq Z$ such that

$$\mathcal{U}' \subseteq \{U(I, h, \epsilon) : I \subseteq D \text{ is finite}, h \in \mathbb{R}^I, \epsilon > 0\}.$$

Let $D' \subseteq X$ be the linear span of D over the rationals. Then D' is again countable, and its $\mathfrak{T}$-closure Y is a linear subspace of X (4A4Bi). **?** If $Z \not\subseteq Y$, then $\mu(X \setminus Y) > 0$. But, writing

$$Y^\circ = \{f : f \in X^*, f(x) \leq 0 \text{ for every } x \in Y\} = \{f : f \in X^*, f(x) = 0 \text{ for every } x \in Y\},$$

$X \setminus Y$ must be $\bigcup_{f\in Y^\circ}\{x : |f(x)| > 0\}$, by 4A4Eb. Because μ is τ-additive, there must be an $f \in Y^\circ$ such that $\mu\{x : |f(x)| > 0\} > 0$. Let $n \in \mathbb{N}$ be such that $f \in V_n^\circ$. Since $f(x) = 0$ for every $x \in D$, $f\restriction Z$ belongs to the same members of $\mathcal{V}_n'$ as the zero function; since $\mathcal{V}_n'$ is a base for the Hausdorff subspace topology of K_n, $f\restriction Z$ actually is the zero function, and $\{x : |f(x)| > 0\} \subseteq X \setminus Z$, so $\mu Z < \mu X$, contrary to the choice of Z. **X**

Thus $Z \subseteq Y$. Because $Y = \overline{D'}$ is $\mathfrak{T}$-separable, and $\mathfrak{T}$ is metrizable, Z is also $\mathfrak{T}$-separable (4A2P(a-iv)).

(b) The subspace topology $\mathfrak{T}_Y$ induced on Y by $\mathfrak{T}$ is a separable metrizable locally convex linear space topology, so the Borel σ-algebras of $\mathfrak{T}_Y$ and the associated weak topology $\mathfrak{T}_s(Y, Y^*)$ are equal (4A3V). But $\mathfrak{T}_s(Y, Y^*)$ is just the subspace topology induced on Y by $\mathfrak{T}_s$ (4A4Ea), Accordingly the subspace measure μ_Y on Y is $\mathfrak{T}_s(Y, Y^*)$-quasi-Radon (415B). Since every $\mathfrak{T}_Y$-open set is $\mathfrak{T}_s(Y, Y^*)$-Borel, μ_Y is a topological measure for $\mathfrak{T}_Y$. Since $\mathfrak{T}_Y$ is finer than $\mathfrak{T}_s(Y, Y^*)$, μ_Y is effectively locally finite for $\mathfrak{T}_Y$ and inner regular with respect to the $\mathfrak{T}_Y$-closed sets, and therefore is a quasi-Radon measure for $\mathfrak{T}_Y$ (415D(i)).

By 415J, there is a measure $\tilde{\mu}$ on X, quasi-Radon for $\mathfrak{T}$, such that $\tilde{\mu}E = \mu_Y(E \cap Y)$ whenever $\tilde{\mu}$ measures E. But as Y is $\mathfrak{T}$-closed and μ-conegligible, and μ is complete, we have $\mu = \tilde{\mu}$, and μ is quasi-Radon for $\mathfrak{T}$.

(c) If X is complete and μ is locally finite with respect to $\mathfrak{T}$, then $(X, \mathfrak{T})$ is a pre-Radon space (434Jg), so μ is a Radon measure for $\mathfrak{T}$ (434Jb).

466B Corollary (Compare 462G.) If X is a Banach space and μ is a totally finite measure on X which is quasi-Radon for the weak topology of X, it is a Radon measure for both the norm topology and the weak topology.

proof By 466A, μ is a Radon measure for the norm topology; by 418I, or otherwise, it is a Radon measure for the weak topology.

Remark Thus Banach spaces, with their weak topologies, are pre-Radon.

466C Definition A normed space X has a **Kadec norm** (also called **Kadec-Klee norm**) if the norm and weak topologies coincide on the sphere $\{x : \|x\| = 1\}$.

Example For any set I, any $p \in [1, \infty[$, the Banach space $\ell^p(I)$ has a Kadec norm. **P** If $x \in \ell^p(I)$ and $\|x\|_p = 1$ and $\epsilon > 0$, let $J \subseteq I$ be a finite set such that $\sum_{i \in I \setminus J} |x(i)|^p \leq \epsilon$. Set $H = \{y : y \in \ell^p(I), \sum_{i \in J} |y(i) - x(i)|^p < \epsilon\}$; then H is open for the weak topology of $\ell^p(I)$. **Q**

For further examples, see §467.

466D Proposition (Hansell 01) Let X be a normed space with a Kadec norm. Then there is a network for the norm topology on X expressible in the form $\bigcup_{n \in \mathbb{N}} \mathcal{V}_n$, where for each $n \in \mathbb{N}$ $\mathcal{V}_n$ is an isolated family for the weak topology and $\bigcup \mathcal{V}_n$ is the difference of two closed sets for the weak topology.

proof Let $\mathcal{U}$ be a σ-disjoint base for the norm topology of X (4A2L(h-ii)); express it as $\bigcup_{n \in \mathbb{N}} \mathcal{U}_n$ where every $\mathcal{U}_n$ is disjoint. For rational numbers q, q' with $0 < q < q'$, set $S_{qq'} = \{x : q < \|x\| \leq q'\}$, and for $A \subseteq X$ write $W(A, q, q')$ for the interior of $A \cap S_{qq'}$ taken in the subspace weak topology of $S_{qq'}$. Set $\mathcal{V}_{nqq'} = \{W(U, q, q') : U \in \mathcal{U}_n\}$, so that $\mathcal{V}_{nqq'}$ is a disjoint family of relatively-weakly-open subsets of $S_{qq'}$, and is an isolated family for the weak topology. Now $\bigcup_{n \in \mathbb{N}, q, q' \in \mathbb{Q}, 0 < q < q'} \mathcal{V}_{nqq'}$ is a network for the norm topology on $X \setminus \{0\}$. **P** If $x \in X \setminus \{0\}$ and $\epsilon > 0$, then take $n \in \mathbb{N}$, $U \in \mathcal{U}_n$ such that $x \in U \subseteq \{y : \|y - x\| \leq \epsilon\}$. Let $\delta > 0$ be such that $\{y : \|y - x\| \leq \delta\} \subseteq U$. Next, because $\| \, \|$ is a Kadec norm, there is a weak neighbourhood V of 0 such that $\|y - x\| \leq \frac{1}{2}\delta$ whenever $y \in x - V$ and $\|y\| = \|x\|$. Let V' be an open weak neighbourhood of 0 such that $V' + V' \subseteq V$. Let $\eta > 0$ be such that $\eta < 1$, $\eta\|x\| \leq \frac{1}{2}\delta$ and $y \in V'$ whenever $\|y\| \leq \eta\|x\|$. If $y \in x - V'$ and $(1 - \eta)\|x\| \leq \|y\| \leq (1 + \eta)\|x\|$, then $\frac{\|x\|}{\|y\|} y \in x + V$. Since

$$\|y - \frac{\|x\|}{\|y\|} y\| = |1 - \frac{\|y\|}{\|x\|}| \|x\| \leq \eta\|x\|,$$

$$x - \frac{\|x\|}{\|y\|} y = (x - y) + (y - \frac{\|x\|}{\|y\|} y) \in V' + V' \subseteq V,$$

so $\|x - \frac{\|x\|}{\|y\|} y\| \leq \frac{1}{2}\delta$ and $\|x - y\| \leq \delta$ and $y \in U$. This means that if we take q, $q' \in \mathbb{Q}$ such that $(1 - \eta)\|x\| \leq q \leq \|x\| \leq q' \leq (1 + \eta)\|x\|$, $(x - V') \cap S_{qq'} \subseteq U$ and $x \in W(U, q, q') \in \mathcal{V}_{nqq'}$. Since of course $W(U, q, q') \subseteq U \subseteq \{y : \|y - x\| \leq \epsilon\}$, and x and ϵ are arbitrary, we have the result. **Q**

To get a σ-isolated family for the weak topology which is a network for the norm topology on the whole of X, we just have to add the singleton set $\{0\}$. To see that the union of each of our isolated families is the difference of two weakly open sets, observe that $\bigcup \mathcal{V}_{nqq'}$ is a relatively weakly open subset of $S_{qq'}$, which is the difference of the weakly open sets $\{x : \|x\| > q\}$ and $\{x : \|x\| > q'\}$.

466E Corollary Let X be a normed space with a Kadec norm.
(a) The norm and weak topologies give rise to the same Borel σ-algebras.
(b) The weak topology has a σ-isolated network, so is hereditarily weakly θ-refinable.

proof (a) Write $\mathcal{B}_{\| \, \|}$, $\mathcal{B}_{\mathfrak{T}_s}$ for the Borel σ-algebras for the weak and norm topologies. Of course $\mathcal{B}_{\mathfrak{T}_s} \subseteq \mathcal{B}_{\| \, \|}$. Let $\langle \mathcal{V}_n \rangle_{n \in \mathbb{N}}$ be a sequence covering a network for the norm topology as in 466D. Because $\mathcal{V}_n$ is (for the weak topology) isolated and its union belongs to $\mathcal{B}_{\mathfrak{T}_s}$, $\bigcup \mathcal{W} \in \mathcal{B}_{\mathfrak{T}_s}$ for every $\mathcal{W} \subseteq \mathcal{V}_n$, $n \in \mathbb{N}$. But this means that $\bigcup \mathcal{W} \in \mathcal{B}_{\mathfrak{T}_s}$ for every $\mathcal{W} \subseteq \mathcal{V} = \bigcup_{n \in \mathbb{N}} \mathcal{V}_n$; and as $\bigcup_{n \in \mathbb{N}} \mathcal{V}_n$ is a network for the norm topology, every norm-open set belongs to $\mathcal{B}_{\mathfrak{T}_s}$, and $\mathcal{B}_{\| \, \|} \subseteq \mathcal{B}_{\mathfrak{T}_s}$. Thus the two Borel σ-algebras are equal.

(b) Of course $\mathcal{V}$ is also a network for the weak topology, so the weak topology has a σ-isolated network; by 438Ld, it is hereditarily weakly θ-refinable.

466F Proposition Let X be a Banach space with a Kadec norm. Then the following are equiveridical:
(i) X is a Radon space in its norm topology;
(ii) X is a Radon space in its weak topology;
(iii) the weight of X (for the norm topology) is measure-free in the sense of §438.

proof (a)(i) $\iff$ (ii) By 466Ea, the norm and weak topologies give rise to the same algebra $\mathcal{B}$ of Borel sets. If X is a Radon space in its norm topology, then any totally finite measure with domain $\mathcal{B}$ is inner regular with respect to the norm-compact sets, therefore inner regular with respect to the weakly compact sets, and X is Radon in its weak topology. If X is a Radon space in its weak topology, then any totally finite measure μ with domain $\mathcal{B}$ has a completion $\hat{\mu}$ which is a Radon measure for the weak topology, therefore also for the norm topology, by 466B; as μ is arbitrary, X is a Radon space for the norm topology.

(b)(i) $\iff$ (iii) is 438H.

466G Definition A partially ordered set X has the **σ-interpolation property** or **countable separation property** if whenever A, B are non-empty countable subsets of X and $x \leq y$ for every $x \in A$, $y \in B$, then there is a $z \in X$ such that $x \leq z \leq y$ for every $x \in A$, $y \in B$. A Dedekind σ-complete partially ordered set (314Ab) always has the σ-interpolation property.

466H Proposition (Jayne & Rogers 95) Let X be a Riesz space with a Riesz norm, given its weak topology $\mathfrak{T}_s = \mathfrak{T}_s(X, X^*)$. Suppose that ($\alpha$) X has the σ-interpolation property (β) there is a strictly increasing family $\langle p_\xi \rangle_{\xi<\omega_1}$ in X. Then there is a $\mathfrak{T}_s$-Borel probability measure μ on X such that

(i) μ is not inner regular with respect to the $\mathfrak{T}_s$-closed sets;

(ii) μ is not τ-additive for the topology $\mathfrak{T}_s$;

(iii) μ has no extension to a norm-Borel measure on X.

Accordingly $(X, \mathfrak{T}_s)$ is not a Radon space (indeed, is not Borel-measure-complete).

proof (a) Let K be the set

$$\{f : f \in X^*, f \geq 0, \|f\| \leq 1\} = \{f : \|f\| \leq 1\} \cap \textstyle\bigcap_{x \in X^+} \{f : f(x) \geq 0\},$$

so that K is a weak*-closed subset of the unit ball of X^* and is weak*-compact. Because X^* is a solid linear subspace of the order-bounded dual $X^\sim$ of X (356Da), every member of X^* is the difference of two non-negative members of X^*, and K spans X^*. We shall need to know that if $x < y$ in X, there is an $f \in K$ such that $f(x) < f(y)$; set $f = \frac{1}{\|g\|}|g|$ where $g \in X^*$ is such that $g(x) \neq g(y)$. (Recall that the norm of X^* is a Riesz norm, as also noted in 356Da.)

Set

$$A = \textstyle\bigcup_{\xi<\omega_1} \{x : x \in X, x \leq p_\xi\};$$

then every sequence in A has an upper bound in A, but A has no greatest member. It follows that if $B \subseteq K$ is countable there is an $x \in A$ such that $f(x) = \sup_{y \in A} f(y)$ for every $f \in B$, so that $f(x) = f(y)$ whenever $x \leq y \in A$ and $f \in B$.

Let $\mathcal{E}$ be the family of those sets $E \subseteq X$ such that $A \cap E$ is cofinal with A. Observe that if $\langle E_n \rangle_{n \in \mathbb{N}}$ is any sequence of subsets of X, and $\bigcup_{n \in \mathbb{N}} E_n \in \mathcal{E}$, then some E_n belongs to $\mathcal{E}$. **P?** Otherwise, there is for each $n \in \mathbb{N}$ an $x_n \in A$ such that $x_n \not\leq y$ for every $y \in A \cap E_n$. Now there is an $x \in A$ such that $x_n \leq x$ for every $n \in \mathbb{N}$, and $x \not\leq y$ for every $y \in \bigcup_{n \in \mathbb{N}} E_n$. **XQ**

(b) If $G \in \mathcal{E}$ is a $\mathfrak{T}_s$-open set, there is a $k \in \mathbb{N}$ such that

for every $z \in A$ there are $x \in A$ and $f_0, \ldots, f_k \in K$ such that $x \geq z$ and $\{y : y \in X, |f_i(y-x)| \leq 2^{-k}$ for every $i \leq k\}$ is included in G.

P For each $k \in \mathbb{N}$ let H_k be the set of those $x \in X$ such that $\{y : |f_i(y-x)| \leq 2^{-k}$ for every $i \leq k\}$ is included in G for some $f_0, \ldots, f_k \in K$. Because the linear span of K is X^*, and G is $\mathfrak{T}_s$-open, $G = \bigcup_{k \in \mathbb{N}} H_k$. So, as remarked in (a), there is some $k \in \mathbb{N}$ such that $H_k \in \mathcal{E}$, and this k will serve. **Q**

(c) (The key.) If $\langle G_n \rangle_{n \in \mathbb{N}}$ is any sequence of $\mathfrak{T}_s$-open sets belonging to $\mathcal{E}$, then $\bigcap_{n \in \mathbb{N}} G_n \in \mathcal{E}$. **P** Start from any $z^* \in A$. For each $n \in \mathbb{N}$, choose $k_n \in \mathbb{N}$ as in (b), so that there is a family $\langle f_{nzi} \rangle_{z \in A, i \leq k_n}$ in K such that

for every $z \in A$ there is an $x \in A$ such that $x \geq z$ and

$$\{y : |f_{nzi}(y-x)| \leq 2^{-k_n} \ \forall\ i \leq k_n\} \subseteq G_n.$$

Let $\mathcal{F}$ be any ultrafilter on A containing $\{x : x \in A, x \geq z\}$ for every $z \in A$, and write $f_{ni} = \lim_{z \to \mathcal{F}} f_{nzi}$ for $n \in \mathbb{N}$ and $i \leq k_n$, the limit being taken for the weak* topology on K. Let $z_1^* > z^*$ be such that $z_1^* \in A$ and $f_{ni}(x - z_1^*) = 0$ whenever $x \in A$, $x \geq z_1^*$, $n \in \mathbb{N}$ and $i \leq k_n$.

Choose sequences $\langle x_n \rangle_{n \in \mathbb{N}}$, $\langle y_n \rangle_{n \in \mathbb{N}}$ and $\langle z_n \rangle_{n \in \mathbb{N}}$ in A inductively, as follows. Set $y_0 = z_1^*$. Given y_n, the set

$$C_n = \{z : z \in A, z \geq y_n, |(f_{nzi} - f_{ni})(y_n - z_1^*)| \leq 2^{-k_n} \text{ for every } i \leq k_n\}$$

belongs to $\mathcal{F}$, so is not empty; take $z_n \in C_n$. Because $y_n \geq z_1^*$, we have $f_{ni}(y_n - z_1^*) = 0$ and $|f_{nz_ni}(y_n - z_1^*)| \leq 2^{-k_n}$, for every $i \leq k_n$. Let $x_n \in A$ be such that $x_n \geq z_n$ and $\{y : |f_{nz_ni}(y - x_n)| \leq 2^{-k_n} \text{ for every } i \leq k_n\} \subseteq G_n$. Now let $y_{n+1} \in A$ be such that $y_{n+1} \geq x_n$ and $f_{nz_ni}(y - y_{n+1}) = 0$ whenever $y \in A$ and $y \geq y_{n+1}$. Continue.

At the end of the induction, let z_2^* be an upper bound for $\{y_n : n \in \mathbb{N}\}$ in A. For $n \in \mathbb{N}$, set

$$u_n = z_1^* + \textstyle\sum_{j=0}^{n} x_j - y_j, \quad v_n = u_n + z_2^* - y_{n+1}.$$

Then $\langle u_n \rangle_{n \in \mathbb{N}}$ is non-decreasing and $u_n \leq v_n \leq z_2^*$ for every $n \in \mathbb{N}$; moreover,

$$v_n - v_{n+1} = y_{n+1} - x_{n+1} - y_{n+1} + y_{n+2} \geq 0$$

for every n, so $\langle v_n \rangle_{n \in \mathbb{N}}$ is non-increasing, and $u_m \leq v_n$ for all m, $n \in \mathbb{N}$. Because X has the σ-interpolation property, there is an $x \in X$ such that $u_n \leq x \leq v_n$ for every $n \in \mathbb{N}$. Since $z_1^* \leq x \leq z_2^*$, $x \in A$ and $x > z^*$.

Take any $n \in \mathbb{N}$. Then

$$f_{nz_ni}(x - u_n) \leq f_{nz_ni}(v_n - u_n) = f_{nz_ni}(z_2^* - y_{n+1}) = 0$$

for every $i \leq k_n$. On the other hand,

$$x_n - u_n = (y_n - z_1^*) - \textstyle\sum_{j=0}^{n-1}(x_j - y_j)$$

lies between 0 and $y_n - z_1^*$, so

$$0 \leq f_{nz_ni}(x_n - u_n) \leq 2^{-k_n}$$

for every $i \leq k_n$, and $|f_{nz_ni}(x - x_n)| \leq 2^{-k_n}$ for every i. Thus $x \in G_n$. As n is arbitrary, $x \in \bigcap_{n \in \mathbb{N}} G_n$.

As $x > z^*$, this shows that z^* is not an upper bound of $\bigcap_{n \in \mathbb{N}} G_n \cap A$. As z^* is arbitrary, $\bigcap_{n \in \mathbb{N}} G_n \in \mathcal{E}$. **Q**

(d) Set

$$\mathcal{K}_0 = \{G \setminus H : G, H \in \mathfrak{T}_s, G \in \mathcal{E}, H \notin \mathcal{E}\}.$$

Then $\bigcap_{n \in \mathbb{N}} E_n \neq \emptyset$ for any sequence $\langle E_n \rangle_{n \in \mathbb{N}}$ in $\mathcal{K}_0$. **P** Express each E_n as $G_n \setminus H_n$ where G_n, H_n are $\mathfrak{T}_s$-open, $G_n \in \mathcal{E}$ and $H_n \notin \mathcal{E}$. Then $\bigcup_{n \in \mathbb{N}} H_n \notin \mathcal{E}$, as noted in (a), while $\bigcap_{n \in \mathbb{N}} G_n \in \mathcal{E}$, by (c); so $\bigcap_{n \in \mathbb{N}} E_n = \bigcap_{n \in \mathbb{N}} G_n \setminus \bigcup_{n \in \mathbb{N}} H_n$ is non-empty. **Q**

It follows that $\mathcal{K} = \mathcal{K}_0 \cup \{\emptyset\}$ is a countably compact class in the sense of 413L. Moreover, $E \cap E' \in \mathcal{K}$ for all E, $E' \in \mathcal{K}$ (using (b) and (c) again), so if we define $\phi_0 : \mathcal{K} \to \{0, 1\}$ by writing $\phi_0(E) = 1$ for $E \in \mathcal{K}_0$, $\phi_0(\emptyset) = 0$, then $\mathcal{K}$ and ϕ_0 will satisfy all the conditions of 413M. There is therefore a measure $\hat{\mu}$ on X extending ϕ_0 and inner regular with respect to $\mathcal{K}_\delta$, the family of sets expressible as intersections of sequences in $\mathcal{K}$. The domain of $\hat{\mu}$ must include every member of $\mathcal{K}$; but if $G \in \mathfrak{T}_s$ then either G or $X \setminus G$ belongs to $\mathcal{K}_0$, so is measured by $\hat{\mu}$, and $\hat{\mu}$ is a topological measure.

We need to observe that, because ϕ_0 takes only the values 0 and 1, $\hat{\mu}E \leq 1$ for every $E \in \mathcal{K}_\delta$, and $\hat{\mu}X \leq 1$; since $\phi_0 X = 1$, $\hat{\mu}X = 1$ and $\hat{\mu}$ is a probability measure.

(e) We may therefore take μ to be the restriction of $\hat{\mu}$ to the algebra $\mathcal{B}$ of Borel sets, and μ is a $\mathfrak{T}_s$-Borel probability measure. Now μ is not inner regular with respect to the $\mathfrak{T}_s$-closed sets. **P** For each $\xi < \omega_1$, $p_\xi < p_{\xi+1} < p_{\xi+2}$, so there are g_ξ, $h_\xi \in K$ such that $g_\xi(p_\xi) < g_\xi(p_{\xi+1})$ and $h_\xi(p_{\xi+1}) < h_\xi(p_{\xi+2})$. Let $D \subseteq \omega_1$ be any set such that D and $\omega_1 \setminus D$ are both uncountable, and set

$$G = \textstyle\bigcup_{\xi \in D}\{x : g_\xi(p_\xi) < g_\xi(x), h_\xi(x) < h_\xi(p_{\xi+2})\}.$$

Then $G \in \mathfrak{T}_s$, and $p_{\xi+1} \in G$ for every $\xi \in D$, so $G \in \mathcal{E}$ and $\mu G = \phi_0 G = 1$. On the other hand, if $\eta \in \omega_1 \setminus D$, then for every $\xi \in D$ either $\xi < \eta$ and $h_\xi(p_{\xi+2}) \leq h_\xi(p_{\eta+1})$, or $\xi > \eta$ and $g_\xi(p_{\eta+1}) \leq g_\xi(p_\xi)$; thus $p_{\eta+1} \notin G$

for any $\eta \in \omega_1 \setminus D$, and $X \setminus G \in \mathcal{E}$. But this means that if $F \subseteq G$ is closed then $X \setminus F \in \mathcal{K}_0$ and $\mu F = 0$. Thus $\mu G > \sup_{F \subseteq G \text{ is closed}} \mu F$. **Q**

(f) Because $\mathfrak{T}_s$ is regular, μ cannot be τ-additive, by 414Mb. It follows at once that $(X, \mathfrak{T}_s)$ is not Borel-measure-complete, and in particular is not a Radon space. To see that μ has no extension to a norm-Borel measure, we need to look again at the set A. For each $\xi < \omega_1$, $F_\xi = \{x : x \leq p_\xi\}$. Then every F_ξ is norm-closed (354Bc) and $\langle F_\xi \rangle_{\xi < \omega_1}$ is an increasing family with union A. Consequently, A is norm-closed (4A2Ld, 4A2Ka). At the same time, every F_ξ is convex (cf. 351Ce), so A is also convex. It follows that A, like every F_ξ, is $\mathfrak{T}_s$-closed (3A5Ee). So μ measures A and every F_ξ. Because $X \setminus F_\xi$ is a $\mathfrak{T}_s$-open set belonging to $\mathcal{E}$, $\mu F_\xi = 0$ for every $\xi < \omega_1$; because $X \setminus A$ is a $\mathfrak{T}_s$-open set not belonging to $\mathcal{E}$, $\mu A = 1$.

But ω_1 is a measure-free cardinal (438Cd), so 438I tells us that $\lambda A = \sup_{\xi < \omega_1} \lambda F_\xi$ for any semi-finite norm-Borel measure λ on X. Thus μ has no extension to a norm-Borel measure, and the proof is complete.

466I Examples The following spaces satisfy the hypotheses of 466H.

(a) (Talagrand 78a, or Talagrand 84, 16-1-2) $X = \ell^\infty(I)$ or $\{x : x \in \ell^\infty(I), \{i : x(i) \neq 0\}$ is countable$\}$, where I is uncountable. **P** X has the σ-interpolation property because it is Dedekind complete, and if $\langle i_\xi \rangle_{\xi < \omega_1}$ is any family of distinct elements of I, we can set $p_\xi(i_\eta) = 1$ for $\eta \leq \xi$, $p_\xi(i) = 0$ for all other $i \in I$ to obtain a strictly increasing family $\langle p_\xi \rangle_{\xi < \omega_1}$ in X. **Q**

(b) (de Maria & Rodriguez-Salinas 91) $X = \ell^\infty / \boldsymbol{c}_0$.

P (i) To see that X has the σ-interpolation property, let A, $B \subseteq X$ be non-empty countable sets such that $u \leq v$ for all $u \in A$, $v \in B$. Let $\langle x_n \rangle_{n \in \mathbb{N}}$, $\langle y_n \rangle_{n \in \mathbb{N}}$ be sequences in ℓ^∞ such that $A = \{x_n^\bullet : n \in \mathbb{N}\}$ and $B = \{y_n^\bullet : n \in \mathbb{N}\}$. Set $\tilde{x}_n = \sup_{i \leq n} x_i$, $\tilde{y}_n = \inf_{i \leq n} y_i$ for $n \in \mathbb{N}$; then $\tilde{x}_n^\bullet \leq \tilde{y}_n^\bullet$, so $(\tilde{x}_n - \tilde{y}_n)^+ \in \boldsymbol{c}_0$. Set

$$k_n = \max(\{n\} \cup \{i : \tilde{x}_n(i) \geq \tilde{y}_n(i) + 2^{-n}\})$$

for $n \in \mathbb{N}$, and define $x \in \ell^\infty$ by writing

$$\begin{aligned} x(i) &= 0 \text{ if } i \leq k_0, \\ &= \tilde{x}_n(i) \text{ if } k_n < i \leq k_{n+1}. \end{aligned}$$

Then it is easy to check that $u \leq x^\bullet \leq v$ for every $u \in A$, $v \in B$; as A and B are arbitrary, X has the σ-interpolation property.

(ii) To see that X has the other property, recall that there is a family $\langle I_\xi \rangle_{\xi < \omega_1}$ of infinite subsets of $\mathbb{N}$ such that $I_\xi \setminus I_\eta$ is finite if $\eta \leq \xi$, infinite if $\xi < \eta$ (4A1Fa). Setting $p_\xi = \chi(\mathbb{N} \setminus I_\xi)^\bullet$, we have a strictly increasing family $\langle p_\xi \rangle_{\xi < \omega_1}$ in X. **Q**

466J Proposition Let X be a linear topological space and Σ its cylindrical σ-algebra. If μ and ν are probability measures with domain Σ such that $\int e^{if(x)} \mu(dx) = \int e^{if(x)} \nu(dx)$ for every $f \in X^*$, then $\mu = \nu$.

proof Define $T : X \to \mathbb{R}^{X^*}$ by setting $(Tx)(f) = f(x)$ for $f \in X^*$, $x \in X$. Then T is linear and continuous for the weak topology of X. So if $F \subseteq \mathbb{R}^{X^*}$ is a Baire set for the product topology of $\mathbb{R}^{X^*}$, $T^{-1}[F]$ is a Baire set for the weak topology of X (4A3Kc) and belongs to Σ (4A3U). We therefore have Baire measures μ', ν' on $\mathbb{R}^{X^*}$ defined by saying that $\mu' F = \mu T^{-1}[F]$ and $\nu' F = \nu T^{-1}[F]$ for every Baire set $F \subseteq \mathbb{R}^{X^*}$.

If $h : \mathbb{R}^{X^*} \to \mathbb{R}$ is a continuous linear functional, it can be expressed in the form $h(z) = \sum_{i=0}^n \alpha_i z(f_i)$ where $f_0, \ldots, f_n \in X^*$ and $\alpha_0, \ldots, \alpha_n \in \mathbb{R}$. So

$$h(Tx) = \sum_{i=0}^n \alpha_i (Tx)(f_i) = \sum_{i=0}^n \alpha_i f_i(x) = f(x)$$

for every $x \in X$, where $f = \sum_{i=0}^n \alpha_i f_i$. This means that

$$\int e^{ih(z)} \mu'(dz) = \int e^{ih(Tx)} \mu(dx) = \int e^{if(x)} \mu(dx) = \int e^{if(x)} \nu(dx) = \int e^{ih(z)} \nu'(dz).$$

As h is arbitrary, $\mu' = \nu'$ (454Ma).

Now let Σ' be the family of subsets of X of the form $T^{-1}[F]$ where $F \subseteq \mathbb{R}^{X^*}$ is a Baire set. This is a σ-algebra and contains all sets of the form $\{x : f(x) \geq \alpha\}$ where $f \in X^*$ and $\alpha \in \mathbb{R}$. So every member of X^* is Σ'-measurable and Σ' must include the cylindrical σ-algebra of X. Since μ and ν agree on Σ' they must be identical.

466K Proposition If X is a locally convex linear topological space and μ, ν are quasi-Radon probability measures on X such that $\int e^{if(x)}\mu(dx) = \int e^{if(x)}\nu(dx)$ for every $f \in X^*$, then $\mu = \nu$.

proof Write $\mathfrak{T}$ for the given topology on X and $\mathfrak{T}_s = \mathfrak{T}_s(X, X^*)$ for the weak topology. By 466J, μ and ν must agree on the cylindrical σ-algebra Σ of X. Since Σ includes a base for $\mathfrak{T}_s$, every weakly open set G is the union of an upwards-directed family of open sets belonging to Σ; as μ and ν are τ-additive, $\mu G = \nu G$. Consequently μ and ν agree on $\mathfrak{T}_s$-closed sets, and therefore on $\mathfrak{T}$-closed convex sets (4A4Ed). Write $\mathcal{H}$ for the family of $\mathfrak{T}$-open sets which are expressible as the union of a non-decreasing sequence of $\mathfrak{T}$-closed convex sets; then μ and ν agree on $\mathcal{H}$. If τ is a $\mathfrak{T}$-continuous seminorm on X, $x_0 \in X$ and $\alpha > 0$, then $\{x : \tau(x - x_0) < \alpha\} \in \mathcal{H}$; and sets of this kind constitute a base for $\mathfrak{T}$ (4A4Cb). Also the intersection of two members of $\mathcal{H}$ belongs to $\mathcal{H}$. By 415H(v), $\mu = \nu$.

Remark This generalizes 285M and 454Xk, which are the special cases $X = \mathbb{R}^r$ (for finite r) and $X = \mathbb{R}^I$.

466L Proposition Suppose that X and Y are Banach spaces and that $T : X \to Y$ is a linear operator such that $gT : X \to \mathbb{R}$ is universally Radon-measurable, in the sense of 434Ec, for every $g \in Y^*$. Then T is continuous.

proof ? Suppose, if possible, otherwise. Then there is a $g \in Y^*$ such that gT is not continuous (4A4Ib). For each $n \in \mathbb{N}$, take $x_n \in X$ such that $\|x_n\| = 2^{-n}$ and $g(Tx_n) > 2n$. Define $h : \{0,1\}^{\mathbb{N}} \to X$ by setting $h(t) = \sum_{n=0}^{\infty} t(n)x_n$ (4A4Ie). Then h is continuous, because $\|h(t) - h(t')\| \leq \sum_{n=0}^{\infty} 2^{-n}|t(n) - t'(n)|$ for all t, $t' \in \{0,1\}^{\mathbb{N}}$. Let ν be the usual measure on $\{0,1\}^{\mathbb{N}}$; then the image measure $\mu = \nu h^{-1}$ is a Radon measure on X (418I), so gT must be $\operatorname{dom}\mu$-measurable, and $\phi = gTh$ is $\operatorname{dom}\nu$-measurable. In this case there is an $m \in \mathbb{N}$ such that $E = \{t : |\phi(t)| \leq m\}$ has measure greater than $\frac{1}{2}$. But as $g(Tx_m) > 2m$, we see that if $t \in E$ then $t' \notin E$, where t' differs from t at the mth coordinate only, so that $|\phi(t) - \phi(t')| = g(Tx_m)$. Since the map $t \mapsto t'$ is an automorphism of the measure space $(\{0,1\}^{\mathbb{N}}, \nu)$, $\nu E \leq \frac{1}{2}$, which is impossible. **X**

466M Corollary If X is a Banach space, Y is a separable Banach space, and $T : X \to Y$ is a linear operator such that the graph of T is a Souslin-F set in $X \times Y$, then T is continuous.

proof It is enough to show that $T\restriction Z$ is continuous for every separable closed linear subspace Z of X (because then it must be sequentially continuous, and we can use 4A2Ld). Write $\Gamma \subseteq X \times Y$ for the graph of T. If $H \subseteq Y$ is open, then $\Gamma \cap (Z \times H)$ is a Souslin-F set in the Polish space $Z \times Y$, so is analytic (423E), and its projection $(T\restriction Z)^{-1}[H]$ is also analytic (423Ba), therefore universally measurable (434Dc). Thus $T\restriction Z : Z \to Y$ is a universally measurable function, and $gT\restriction Z$ must be universally measurable for any $g \in Y^*$ (434Df). By 466L, $T\restriction Z$ is continuous; as Z is arbitrary, T is continuous.

466X Basic exercises (a) Let $(X, \mathfrak{T})$ be a metrizable locally convex linear topological space and μ a totally finite measure on X which is quasi-Radon for the topology $\mathfrak{T}$. Show that μ is quasi-Radon for the weak topology $\mathfrak{T}_s(X, X^*)$.

>(b) Let $\langle e_n \rangle_{n\in\mathbb{N}}$ be the usual orthonormal basis of ℓ^2. Give ℓ^2 the Radon probability measure ν such that $\nu\{e_n\} = 2^{-n-1}$ for every n. Let I be an uncountable set, and set $X = (\ell^2)^I$ with the product linear structure and the product topology $\mathfrak{T}$, each copy of ℓ^2 being given its norm topology; write $\mathfrak{T}_s$ for the weak topology of X. (i) Let λ be the τ-additive product of copies of ν (417G). Show that λ is quasi-Radon for $\mathfrak{T}$ but is not inner regular with respect to the $\mathfrak{T}_s$-closed sets. (ii) Let μ_s be the τ-additive product measure of copies of μ when each copy of ℓ^2 is given its weak topology instead of its norm topology. Show that μ_s is quasi-Radon for $\mathfrak{T}_s$ but does not measure every $\mathfrak{T}$-Borel set. (*Hint*: setting $E = \{e_n : n \in \mathbb{N}\}$, $\mu(E^I) = 1$ and E^I is relatively $\mathfrak{T}_s$-compact.)

>(c) Let X be a metrizable locally convex linear topological space and μ a τ-additive totally finite measure on X with domain the cylindrical σ-algebra of X. Show that μ has an extension to a quasi-Radon measure on X. (*Hint*: 4A3U, 415N.)

(d) Let X be a metrizable locally convex linear topological space which is Lindelöf in its weak topology, and Σ the cylindrical σ-algebra of X. Show that any totally finite measure with domain Σ has an extension to a quasi-Radon measure on X.

>(e) Let X be a separable Banach space. Show that it is a Radon space when given its weak topology. (*Hint*: 4A3V, 467E.)

(f) Let K be a compact metric space, and $C(K)$ the Banach space of continuous real-valued functions on K. Show that the σ-algebra of subsets of $C(K)$ generated by the functionals $x \mapsto x(t) : C(K) \to \mathbb{R}$, for $t \in K$, is just the cylindrical σ-algebra of $C(K)$. (*Hint*: 4A2Pe.) Show that $C(K)$ is a pre-Radon space when given its weak topology. (See 462Z.)

(g) Re-write part (d) of the proof of 466H to avoid any appeal to results from §413.

(h) Let $f : \mathbb{R} \to \mathbb{R}$ be a function such that $f(1) = 1$ and $f(x + y) = f(x) + f(y)$ for all x, $y \in \mathbb{R}$. Show that the following are equiveridical: (i) $f(x) = x$ for every $x \in \mathbb{R}$; (ii) f is continuous at some point; (iii) f is bounded on some non-empty open set; (iv) f is bounded on some Lebesgue measurable set of non-zero measure; (v) f is Lebesgue measurable; (vi) f is Borel measurable; *(vii) f is bounded on some non-meager G_δ set; *(viii) f is $\widehat{\mathcal{B}}$-measurable, where $\widehat{\mathcal{B}}$ is the Baire property algebra of $\mathbb{R}$. (*Hint*: 443Db.)

(i) Set $X = \{x : x \in \mathbb{R}^{\mathbb{N}}, \{n : x(n) \neq 0\} \text{ is finite}\}$, and give X any norm. Show that any linear operator from X to any normed space is universally measurable.

(j) Let X be a locally convex linear topological space and μ, ν two totally finite quasi-Radon measures on X. Show that if μ and ν give the same measure to every half-space $\{x : f(x) \geq \alpha\}$, where $f \in X^*$ and $\alpha \in \mathbb{R}$, then $\mu = \nu$.

(k) Let X be a Hilbert space and μ, ν two totally finite Radon measures on X. Show that if μ and ν give the same measure to every ball $B(x, \delta)$, where $x \in X$ and $\delta \geq 0$, then $\mu = \nu$. (*Hint*: every open half-space is the union of a non-decreasing sequence of balls.)

(l) Let μ be a Radon measure on $\ell^\infty(I)$, where I is any set. Set $f_i(x) = x(i)$ for $x \in \ell^\infty(I)$, $i \in I$. Show that $\{f_i^\bullet : i \in I\}$ is relatively compact in $L^0(\mu)$. (*Hint*: 463Xc.)

>(m) Show that Talagrand's measure, intepreted as a measure on $\ell^\infty(I)$ (464R), is not τ-additive for the weak topology.

466Y Further exercises (a) Give an example of a Hausdorff locally convex linear topological space $(X, \mathfrak{T})$ with a probability measure μ on X which is a Radon measure for the weak topology $\mathfrak{T}_s(X, X^*)$ but not for the topology $\mathfrak{T}$. (*Hint*: take $C = C([0, 1])$ and $X = C^*$ with the Mackey topology for the dual pair (X, C), that is, the topology of uniform convergence on weakly compact subsets of C.)

(b) In 466H, show that there is a Borel set for the norm topology on X which is not a Borel set for the weak topology. (*Hint*: we can adjust the family $\langle p_\xi \rangle_{\xi < \omega_1}$ to ensure that, for some $\epsilon > 0$, $\|p_\xi - p_\eta\| \geq \epsilon$ whenever $\eta < \xi$. For $\xi < \omega_1$ set $F_\xi = \{x : x \leq p_\xi, x \not\leq p_\eta \text{ for any } \eta < \xi\}$. Show that $\bigcup_{\xi \in D} F_\xi$ is norm-Borel for every $D \subseteq \omega_1$, while $\mu^*(\bigcup_{\xi < \omega_1} F_\xi) = 1$.)

(c) Find Banach spaces X and Y and a linear operator from X to Y which is not continuous but whose graph is an F_σ set in $X \times Y$.

466Z Problems (a) Does every probability measure defined on the $\mathfrak{T}_s(\ell^\infty, (\ell^\infty)^*)$-Borel sets of $\ell^\infty = \ell^\infty(\mathbb{N})$ extend to a measure defined on the $\| \|_\infty$-Borel sets?

It is by no means obvious that the Borel sets of ℓ^∞ are different for the weak and norm topologies; for a proof see Talagrand 78B.

(b) Assume that $\mathfrak{c}$ is measure-free. Does it follow that ℓ^∞, with its weak topology, is a Radon space?

Note that a positive answer to 464Z (with $I = \mathbb{N}$) would settle this, since Talagrand's measure, when interpreted as a measure on ℓ^∞, cannot agree on the weakly Borel sets with any Radon measure on ℓ^∞ (466Xl, 466Xm).

466 Notes and comments I have given a proof of 466A using the machinery of §463; when the measure μ is known to be a Radon measure for the weak topology, rather than just a quasi-Radon measure or a τ-additive measure on the cylindrical algebra (466Xc), the theorem is older than this, and for an instructive alternative approach see TALAGRAND 84, 12-1-4. Another proof is in JAYNE & ROGERS 95.

On any Banach space we have at least three important σ-algebras: the norm-Borel σ-algebra (generated by the norm-open sets), the weak-Borel algebra (generated by the weakly open sets) and the cylindrical algebra (generated by the continuous linear functionals). (Note that the Baire σ-algebras corresponding to the norm and weak topologies are the norm-Borel algebra (4A3Kb) and the cylindrical algebra (4A3U).) If our Banach space is naturally represented as a subspace of some $\mathbb{R}^I$ (e.g., because it is a space of continuous functions), then we have in addition the σ-algebra generated by the functionals $x \mapsto x(i)$ for $i \in I$, and the Borel algebra for the topology of pointwise convergence. We correspondingly have natural questions concerning when these algebras coincide, as in 466E and 4A3V and 466Xf, and when a measure on one of the algebras leads to a measure on another, as in 466A-466B.

The question of which Banach spaces are Radon spaces in their norm topologies is, if not exactly 'solved', at least reducible to a classical problem in set theory by the results in §438. It seems much harder to decide which non-separable Banach spaces are Radon spaces in their weak topologies. We have a simple positive result for spaces with Kadec norms (466F), and after some labour a negative result for a couple of standard examples (466I). The case of ℓ^∞ seems still to be open in 'ordinary' set theories (466Zb). ℓ^∞ is of particular importance in this context because the dual of any separable Banach space is isometrically isomorphic to a linear subspace of ℓ^∞ (4A4Id). So a positive answer to either question in 466Z would have very interesting consequences – and would be correspondingly surprising.

466L and 466M belong to a large family of results of the general form: if, between spaces with both topological and algebraic structures, we have a homomorphism (for the algebraic structures) which is not continuous, then it is wildly irregular. I hope to return to some of these ideas in Volume 5. For the moment I just give a version of the classical result that an additive function $f : \mathbb{R} \to \mathbb{R}$ which is Lebesgue measurable must be continuous (466Xh). The definition of 'universally measurable' function which I gave in §434 has a number of paradoxical aspects. I have already remarked that in some contexts we might prefer to use the notion of 'universally Radon-measurable' function; this is also appropriate for 466L. But when our space X, for any reason, has few Borel measures, as in 466Xi, there are correspondingly many universally measurable functions defined on X. Of course 466M can also be thought of as a generalization of the closed graph theorem; but note that, unlike the closed graph theorem, it needs a separable codomain (466Yc).

A curious geometric question concerning measures on metric spaces is the following. If two totally finite Radon measures on a metric space agree on balls, must they be identical? It is known that (even for compact spaces) the answer, in general, is 'no' (DAVIES 71); in Hilbert spaces the answer is 'yes', for non-trivial reasons (466Xk); in any finite-dimensional normed space, the answer is again 'yes' (JACKSON & MAULDIN 99).

*467 Locally uniformly rotund norms

In the last section I mentioned Kadec norms. These are interesting in themselves, but the reason for including them in this book is that in a normed space with a Kadec norm the weak topology has the same Borel sets as the norm topology (466Ea). The same will evidently be true of any space which has an equivalent Kadec norm. Now Kadec norms themselves are not uncommon, but equivalent Kadec norms appear in a striking variety of cases. Here I describe the principal class of spaces (the 'weakly K-countably determined' Banach spaces, 467H) which have equivalent Kadec norms. In fact they have 'locally uniformly rotund' norms, which are much easier to do calculations with.

Almost everything here is pure functional analysis, mostly taken from DEVILLE GODEFROY & ZIZLER 93, which is why I have starred the section. The word 'measure' does not appear until 467P. At that point, however, we find ourselves with a striking result (Schachermayer's theorem) which appears to need the structure theory of weakly compactly generated Banach spaces developed in 467C-467M.

467A Definition Let X be a linear space with a norm $\| \|$. $\| \|$ is **locally uniformly rotund** or **locally uniformly convex** if whenever $\|x\| = 1$ and $\epsilon > 0$, there is a $\delta > 0$ such that $\|x - y\| \leq \epsilon$ whenever $\|y\| = 1$ and $\|x + y\| \geq 2 - \delta$.

If X has a locally uniformly rotund norm, then every subspace of X has a locally uniformly rotund norm.

467B Proposition A locally uniformly rotund norm is a Kadec norm.

proof Let X be a linear space with a locally uniformly rotund norm $\|\,\|$. Set $S_X = \{x : \|x\| = 1\}$. Suppose that G is open for the norm topology and that $x \in G \cap S_X$. Then there is an $\epsilon > 0$ such that $G \supseteq B(x,\epsilon) = \{y : \|y-x\| \leq \epsilon\}$. Let $\delta > 0$ be such that $\|x-y\| \leq \epsilon$ whenever $\|y\| = 1$ and $\|x+y\| \geq 2-\delta$. Now there is an $f \in X^*$ such that $f(x) = \|f\| = 1$ (3A5Ac). So $V = \{y : f(y) > 1-\delta\}$ is open for the weak topology. But if $y \in V \cap S_X$, then $\|x+y\| \geq f(x+y) \geq 2-\delta$, so $\|x-y\| \leq \epsilon$ and $y \in G$. As x is arbitrary, $G \cap S_X$ is open for the weak topology on S_X; as G is arbitrary, the norm and weak topologies agree on S_X.

467C A technical device (a) I will use the following notation for the rest of the section. Let X be a linear space and $p : X \to [0,\infty[$ a seminorm. Define $q_p : X \times X \to [0,\infty[$ by setting

$$q_p(x,y) = 2p(x)^2 + 2p(y)^2 - p(x+y)^2 = (p(x)-p(y))^2 + (p(x)+p(y))^2 - p(x+y)^2$$

for $x \in X$.

(b) A norm $\|\,\|$ on X is locally uniformly rotund iff whenever $x \in X$ and $\epsilon > 0$ there is a $\delta > 0$ such that $\|x-y\| \leq \epsilon$ whenever $q_{\|\,\|}(x,y) \leq \delta$.

P(i) Suppose that $\|\,\|$ is locally uniformly rotund, $x \in X$ and $\epsilon > 0$. (α) If $x = 0$ then $q_{\|\,\|}(x,y) = \|y\|^2 = \|x-y\|^2$ for every y so we can take $\delta = \epsilon^2$. (β) If $x \neq 0$ set $x' = \frac{1}{\|x\|}x$. Let $\eta > 0$ be such that $\|x'-y'\| \leq \frac{1}{2}\epsilon\|x\|$ whenever $\|y'\| = 1$ and $\|x'+y'\| \geq 2-\eta$. Let $\delta > 0$ be such that

$$\delta + 2\sqrt{\delta}\|x\| \leq \eta\|x\|^2, \quad \sqrt{\delta} < \|x\|, \quad \sqrt{\delta} \leq \tfrac{1}{2}\epsilon\|x\|^2.$$

Now if $q_{\|\,\|}(x,y) \leq \delta$, we must have

$$(\|x\| - \|y\|)^2 \leq \delta < \|x\|^2, \quad (\|x\| + \|y\|)^2 - \|x+y\|^2 \leq \delta,$$

so that $y \neq 0$ and

$$\big|\tfrac{1}{\|x\|} - \tfrac{1}{\|y\|}\big|\|y\| = \tfrac{|\|y\|-\|x\||}{\|x\|} \leq \tfrac{\sqrt{\delta}}{\|x\|},$$

$$\|x\| + \|y\| - \|x+y\| \leq \tfrac{\delta}{\|x\|+\|y\|+\|x+y\|} \leq \tfrac{\delta}{\|x\|}.$$

Set $y' = \frac{1}{\|y\|}y$, $y'' = \frac{1}{\|x\|}y$. Then $\|y'\| = 1$, and

$$\|y'-y''\| = \big|\tfrac{1}{\|y\|} - \tfrac{1}{\|x\|}\big|\|y\| \leq \tfrac{\sqrt{\delta}}{\|x\|} \leq \tfrac{1}{2}\epsilon\|x\|.$$

Accordingly

$$\begin{aligned}\|x'+y'\| &\geq \|x'+y''\| - \|y'-y''\| \geq \tfrac{1}{\|x\|}\|x+y\| - \tfrac{\sqrt{\delta}}{\|x\|}\\ &\geq \tfrac{1}{\|x\|}(\|x\| + \|y\| - \tfrac{\delta}{\|x\|}) - \tfrac{\sqrt{\delta}}{\|x\|} = 1 + \tfrac{\|y\|}{\|x\|} - \tfrac{\delta}{\|x\|^2} - \tfrac{\sqrt{\delta}}{\|x\|}\\ &\geq 1 + \tfrac{\|x\|-\sqrt{\delta}}{\|x\|} - \tfrac{\delta}{\|x\|^2} - \tfrac{\sqrt{\delta}}{\|x\|} = 2 - \tfrac{\delta}{\|x\|^2} - \tfrac{2\sqrt{\delta}}{\|x\|} \geq 2-\eta.\end{aligned}$$

But this means that $\|x'-y'\| \leq \frac{1}{2}\epsilon\|x\|$, so that $\|x'-y''\| \leq \epsilon\|x\|$ and $\|x-y\| \leq \epsilon$. As x and ϵ are arbitrary, the condition is satisfied.

(ii) Suppose the condition is satisfied. If $\|x\| = 1$ and $\epsilon > 0$, take $\delta \in]0,2]$ such that $\|x-y\| \leq \epsilon$ whenever $q(x,y) \leq 4\delta$; then if $\|y\| = 1$ and $\|x+y\| \geq 2-\delta$, $q(x,y) = 4 - \|x+y\|^2 \leq 4\delta$ and $\|x-y\| \leq \epsilon$. As x and ϵ are arbitrary, $\|\,\|$ is locally uniformly rotund. **Q**

(c) We have the following elementary facts. Let X be a linear space.

(i) For any seminorm p on X, $q_p(x,y) \geq 0$ for all x, $y \in X$. **P**

$$q_p(x,y) \geq (p(x)+p(y))^2 - p(x+y)^2 \geq 0$$

because $p(x+y) \leq p(x)+p(y)$. **Q**

(ii) Suppose that $\langle p_i \rangle_{i\in I}$ is a family of seminorms on X such that $\sum_{i\in I} p_i(x)^2$ is finite for every $x \in X$. Set $p(x) = \sqrt{\sum_{i\in I} p_i(x)^2}$ for $x \in X$; then p is a seminorm on X and $q_p = \sum_{i\in I} q_{p_i}$. **P** Of course $p(\alpha x) = |\alpha| p(x)$ for $\alpha \in \mathbb{R}$ and $x \in X$. If $x \in X$, then $p(x) = \|\phi(x)\|_2$, where $\phi(x) = \langle p_i(x)\rangle_{i\in I} \in \ell^2(I)$. Now for x, $y \in X$,

$$0 \leq \phi(x+y) \leq \phi(x) + \phi(y)$$

in $\ell^2(I)$, so

$$p(x+y) = \|\phi(x+y)\|_2 \leq \|\phi(x)+\phi(y)\|_2 \leq \|\phi(x)\|_2 + \|\phi(y)\|_2 = p(x)+p(y).$$

Thus p is a seminorm. Now the calculation of $q_p = \sum_{i\in I} q_{p_i}$ is elementary. **Q** In particular, $q_p \geq q_{p_i}$ for every $i \in I$.

(iii) If $\| \|$ is an inner product norm on X, then $q_{\| \|}(x,y) = \|x-y\|^2$ for all x, $y \in X$. **P**

$$\begin{aligned} 2\|x\|^2 + 2\|y\|^2 - \|x+y\|^2 &= 2(x|x) + 2(y|y) - (x+y|x+y) \\ &= (x|x) + (y|y) - (x|y) - (y|x) = (x-y|x-y). \end{aligned}$$ **Q**

467D Lemma Let X be a normed space. Suppose that there are a normed space Y with a locally uniformly rotund norm and a bounded linear operator $T : Y \to X$ such that $T[Y]$ is dense in X and, for every $x \in X$ and $\gamma > 0$, there is a $z \in Y$ such that $\|x-Tz\|^2 + \gamma\|z\|^2 = \inf_{y\in Y} \|x-Ty\|^2 + \gamma\|y\|^2$. Then X has an equivalent locally uniformly rotund norm.

proof (a) For each $n \in \mathbb{N}$, $x \in X$ set

$$p_n(x) = \sqrt{\inf_{y\in Y} \|x-Ty\|^2 + 2^{-n}\|y\|^2}.$$

Then $p_n : X \to [0,\infty[$ is a norm on X, equivalent to $\| \|$. **P** (i) The functionals $(x,y) \mapsto \|x-Ty\|$, $(x,y) \mapsto 2^{-n/2}\|y\|$ from $X \times Y$ to $[0,\infty[$ are both seminorms, so the functional $(x,y) \mapsto \phi(x,y) = \sqrt{\|x-Ty\|^2 + 2^{-n}\|y\|^2}$ also is, by 467C(c-ii). (ii) If $x \in X$ and $\alpha \in \mathbb{R}$, take $z \in Y$ such that $p_n(x) = \phi(x,z)$; then

$$p_n(\alpha x) \leq \phi(\alpha x, \alpha z) = |\alpha|\phi(x,z) = |\alpha| p_n(x).$$

If $\alpha \neq 0$, apply the same argument to see that $p_n(x) \leq |\alpha|^{-1} p_n(\alpha x)$, so that $p_n(\alpha x) = |\alpha| p_n(x)$. (iii) Now take any x_1, $x_2 \in X$. Let z_1, $z_2 \in Y$ be such that $p_n(x_i) = \phi(x_i, z_i)$ for both i. Then

$$\begin{aligned} p_n(x_1+x_2) &= 2p_n(\tfrac{1}{2}x_1 + \tfrac{1}{2}x_2) \leq 2\phi(\tfrac{1}{2}x_1 + \tfrac{1}{2}x_2, \tfrac{1}{2}z_1 + \tfrac{1}{2}z_2) \\ &\leq 2(\tfrac{1}{2}\phi(x_1,z_1) + \tfrac{1}{2}\phi(x_2,z_2)) = p_n(x_1) + p_n(x_2). \end{aligned}$$

Thus p_n is a seminorm. (iv) $p_n(x) \leq \phi(x,0) = \|x\|$ for every $x \in X$. (vi) For any $x \in X$ and $y \in Y$, either $\|Ty\| \geq \frac{1}{2}\|x\|$ and

$$\phi(x,y) \geq 2^{-n/2}\|y\|_2 \geq \frac{1}{2\cdot 2^{n/2}\|T\|}\|x\|,$$

or $\|Ty\| \leq \frac{1}{2}\|x\|$ and

$$\phi(x,y) \geq \|x-Ty\| \geq \frac{1}{2}\|x\|;$$

this shows that $p_n(x) \geq \min(\frac{1}{2}, \frac{1}{2}2^{-n/2}\|T\|^{-1})\|x\|$. (I am passing over the trivial case $X = \{0\}$, $\|T\| = 0$.) In particular, $p_n(x) = 0$ only when $x = 0$. Thus p_n is a norm equivalent to p. **Q**

(c) For any $x \in X$, $\lim_{n\to\infty} p_n(x) = 0$. **P** Let $\epsilon > 0$. Let $y \in Y$ be such that $\|x - Ty\| \leq \epsilon$; then

$$\limsup_{n\to\infty} p_n(x)^2 \leq \limsup_{n\to\infty} \|x - Ty\|^2 + 2^{-n}\|y\|_2^2 \leq \epsilon^2.$$

As ϵ is arbitrary, $\lim_{n\to\infty} p_n(x) = 0$. **Q**

(d) Set $\|x\|' = \sqrt{\sum_{n=0}^{\infty} 2^{-n} p_n(x)^2}$ for $x \in X$. The sum is always finite because $p_n(x) \leq \|x\|$ for every n, so $\|\,\|'$ is a seminorm; and it is a norm equivalent to $\|\,\|$ because p_0 is. Now $\|\,\|'$ is locally uniformly rotund. **P** Take $x \in X$ and $\epsilon > 0$. Let $n \in \mathbb{N}$ be such that $p_n(x) \leq \frac{1}{4}\epsilon$. Choose $y \in Y$ such that $p_n(x)^2 = \|x - Ty\|^2 + 2^{-n}\|y\|^2$. (This is where we really use the hypothesis that the infimum in the definition of p_n is attained.) Let $\delta > 0$ be such that $2^n\delta \leq (\frac{1}{4}\epsilon)^2$ and $\|T\|\|y' - y\| \leq \frac{1}{4}\epsilon$ whenever $q_{\|\,\|}(y', y) \leq 2^{2n}\delta$.

If $q_{\|\,\|'}(x, x') \leq \delta$, then $q_{2^{-n/2}p_n}(x, x') \leq \delta$, by 467C(c-ii), that is, $q_{p_n}(x, x') \leq 2^n\delta$. Let $y' \in Y$ be such that $p_n(x')^2 = \|x' - Ty'\|^2 + 2^{-n}\|y'\|_2^2$. Then

$$\begin{aligned} p_n(x + x')^2 &\leq \|x + x' - Ty - Ty'\|^2 + 2^{-n}\|y + y'\|^2 \\ &\leq (\|x - Ty\| + \|x' - Ty'\|)^2 + 2^{-n}\|y + y'\|^2, \end{aligned}$$

so

$$\begin{aligned} q_{p_n}(x, x') &= 2p_n(x)^2 + 2p_n(x')^2 - p_n(x + x')^2 \\ &\geq 2(\|x - Ty\|^2 + 2^{-n}\|y\|^2) + 2(\|x' - Ty'\|^2 + 2^{-n}\|y'\|^2) \\ &\qquad - (\|x - Ty\| + \|x' - Ty'\|)^2 - 2^{-n}\|y + y'\|^2 \\ &= (\|x - Ty\| - \|x' - Ty'\|)^2 + 2^{-n}(2\|y\|^2 + 2\|y'\|_2^2 - \|y + y'\|^2). \end{aligned}$$

This means that

$$q_{\|\,\|}(y, y') \leq 2^n q_{p_n(x,x')} \leq 2^{2n}\delta,$$

so $\|T\|\|y - y'\| \leq \frac{1}{4}\epsilon$, while

$$\|x - Ty\| + \|x' - Ty'\| \leq 2\|x - Ty\| + \sqrt{q_{p_n}(x, x')} \leq 2p_n(x) + 2^{n/2}\sqrt{\delta} \leq \frac{3}{4}\epsilon.$$

Finally

$$\|x - x'\| \leq \|T\|\|y - y'\| + \|x - Ty\| + \|x' - Ty'\| \leq \tfrac{1}{4}\epsilon + \tfrac{3}{4}\epsilon = \epsilon.$$

As x and ϵ are arbitrary, this shows that $\|\,\|'$ is locally uniformly rotund. **Q**

This completes the proof.

467E Theorem Let X be a separable normed space. Then it has an equivalent locally uniformly rotund norm.

proof (a) It is enough to show that the completion of X has an equivalent locally uniformly rotund norm; since the completion of X is separable, we may suppose that X itself is complete. Let $\langle x_i \rangle_{i\in\mathbb{N}}$ be a sequence in X running over a dense subset of X. Define $T : \ell^2 \to X$ by setting

$$Ty = \sum_{i=0}^{\infty} \frac{y(i)}{2^i(1 + \|x_i\|)} x_i$$

for $y \in \ell^2 = \ell^2(\mathbb{N})$; then Ty is always defined (4A4Ie); T is a linear operator and

$$\|Ty\| \leq \sum_{i=0}^{\infty} 2^{-i}|y(i)| \leq \sqrt{\sum_{i=0}^{\infty} 2^{-2i}}\|y\|_2$$

for every $y \in \ell^2$, by Cauchy's inequality (244E). So T is a bounded linear operator.

(b) T satisfies the conditions of 467D. **P** $T[\ell^2]$ is dense because it contains every x_i. Given $x \in X$ and $\gamma > 0$, $\alpha \geq 0$, the function $y \mapsto \sqrt{\|x - Ty\|^2 + \gamma\|y\|_2^2}$ is a seminorm and norm-continuous, so the set

$$C_\alpha(x) = \{y : y \in \ell^2,\ \|x - Ty\|^2 + \gamma\|y\|_2^2 \leq \alpha^2\}$$

is convex and norm-closed. Consequently, $C_\alpha(x)$ is weakly closed (4A4Ed); since $\|y\|_2 \leq \gamma^{-1/2}\alpha$ for every $y \in C_\alpha(x)$, $C_\alpha(x)$ is weakly compact (4A4Ka). Set $\beta = \inf_{y\in\ell^2} \|x - Ty\|^2 + \gamma\|y\|_2^2$. Then $\{C_\alpha(x) : \alpha > \beta\}$

is a downwards-directed set of non-empty weakly compact sets, so has non-empty intersection; taking any $z \in \bigcap_{\alpha>\beta} C_\alpha(x)$, $\beta = \|x - Tz\|^2 + \gamma\|z\|_2^2$. **Q**

(c) So 467D gives the result.

467F Lemma Let $(X, \|\,\|)$ be a Banach space, and $\langle T_i\rangle_{i\in I}$ a family of bounded linear operators from X to itself such that

(i) for each $i \in I$, the subspace $T_i[X]$ has an equivalent locally uniformly rotund norm,

(ii) for each $x \in X$, $\epsilon > 0$ there is a finite set $J \subseteq I$ such that $\|x - \sum_{i\in J} T_i x\| \leq \epsilon$,

(iii) for each $x \in X$, $\epsilon > 0$ the set $\{i : i \in I, \|T_i x\| \geq \epsilon\}$ is finite.

Then X has an equivalent locally uniformly rotund norm.

proof (a) Let $\|\,\|_i$ be a locally uniformly rotund norm on $X_i = T_i[X]$ equivalent to $\|\,\|$ on X_i. Reducing $\|\,\|_i$ by a scalar multiple if necessary, we may suppose that $\|T_i x\|_i \leq \|x\|$ for every $x \in X$, $i \in I$. By (iii), $\sup_{i\in I} \|T_i x\|$ is finite for every $x \in X$; by the Uniform Boundedness Theorem (3A5Ha), $M = \sup_{i\in I} \sup_{\|x\|\leq 1} \|T_i x\|$ is finite. For finite sets $J \subseteq I$ and $k \geq 1$, set

$$p_{Jk}(x) = \sqrt{\textstyle\sum_{i\in J} \|T_i x\|_i^2 + \frac{1}{k}\sum_{K\subseteq J} \|x - \sum_{i\in K} T_i x\|^2};$$

for $n \in \mathbb{N}$ and $k \geq 1$ set

$$p_k^{(n)}(x) = \sup\{p_{Jk}(x) : J \subseteq I, \#(J) \leq n\}.$$

By 467C(c-ii), as usual, all the p_{Jk} are seminorms, and it follows at once that the $p_k^{(n)}$ are seminorms. Observe that if $K \subseteq I$ is finite, then $\|x - \sum_{i\in K} T_i x\| \leq (1 + M\#(K))\|x\|$ for every x, so if $J \subseteq I$ is finite then

$$p_{Jk}(x) \leq \sqrt{\#(J) + 2^{\#(J)}(1 + M\#(J))}\|x\|,$$

and $p_k^{(n)}(x) \leq \sqrt{n + 2^n(1 + Mn)}\|x\|$ for every $n \in \mathbb{N}$, $k \geq 1$. Setting $\beta_{nk} = 2^{2n+k}$ for n, $k \in \mathbb{N}$,

$$\|x\|' = \sqrt{\textstyle\sum_{n=0}^\infty \sum_{k=1}^\infty \beta_{nk}^{-1} p_k^{(n)}(x)^2}$$

is finite for every $x \in X$, so that $\|\,\|'$ is a seminorm on X; moreover, $\|x\|' \leq \beta\|x\|$ for every $x \in X$, where

$$\beta = \sqrt{\textstyle\sum_{n=0}^\infty \sum_{k=1}^\infty \beta_{nk}^{-1}(n + 2^n(1 + Mn))}$$

is finite. Since we also have

$$\|x\|' \geq \tfrac{1}{\sqrt{2}} p_1^{(0)}(x) = \tfrac{1}{\sqrt{2}} p_{\emptyset 1}(x) = \tfrac{1}{\sqrt{2}}\|x\|$$

for every x, $\|\,\|'$ is a norm on X equivalent to $\|\,\|$.

(b) Now $\|\,\|'$ is locally uniformly rotund. **P** Take $x \in X$ and $\epsilon > 0$. Let $K \subseteq I$ be a finite set such that $\|x - \sum_{i\in K} T_i x\| \leq \frac{1}{4}\epsilon$; we may suppose that $T_i x \neq 0$ for every $i \in K$. Set $\alpha_1 = \min_{i\in K} \|T_i x\|_i$, $J = \{i : i \in I, \|T_i x\|_i \geq \alpha_1\}$ and $\alpha_0 = \sup_{i\in I\setminus J} \|Tx_i\|_i$. (For completeness, if $K = \emptyset$, take $J = \emptyset$, $\alpha_0 = \sup_{i\in I} \|T_i x\|_i$ and $\alpha_1 = \alpha_0 + 1$.) Then J is finite and $\alpha_0 < \alpha_1$, by hypothesis (iii) of the lemma. Set $n = \#(J)$. Let k be so large that $\frac{2^n(Mn+1)}{k}\|x\|^2 < \frac{1}{2}(\alpha_1^2 - \alpha_0^2)$. Let $\eta > 0$ be such that

$$(\beta_{nk} + 1)\eta \leq \min(\tfrac{\epsilon^2}{16k}, \alpha_1^2 - \alpha_0^2),$$

$$\|T_i x - z\| \leq \tfrac{\epsilon}{1+4n} \text{ whenever } i \in K,\ z \in X_i \text{ and } q_{\|\,\|_i}(T_i x, z) \leq (\beta_{nk} + 1)\eta;$$

this is where we use the hypothesis that every $\|\,\|_i$ is locally uniformly rotund (and equivalent to $\|\,\|$ on X_i).

Now suppose that $y \in X$ and $q_{\|\,\|'}(x, y) \leq \eta$. Then $q_{p_k^{(n)}}(x, y) \leq \beta_{nk}\eta$, by 467C(c-ii). Let $L \in [I]^n$ be such that $p_k^{(n)}(x + y)^2 \leq p_{Lk}(x + y)^2 + \eta$. Then

$$\begin{aligned} q_{p_{Lk}}(x, y) &= 2p_{Lk}(x)^2 + 2p_{Lk}(y)^2 - p_{Lk}(x + y)^2 \\ &\leq 2p_k^{(n)}(x)^2 + 2p_k^{(n)}(y)^2 - p_k^{(n)}(x + y)^2 + \eta \leq (\beta_{nk} + 1)\eta. \end{aligned}$$

We also have

$$\begin{aligned}2p_{Lk}(x)^2 &\geq 2p_{Lk}(x)^2 + 2p_{Lk}(y)^2 - 2p_k^{(n)}(y)^2 \geq p_{Lk}(x+y)^2 - 2p_k^{(n)}(y)^2\\ &\geq p_k^{(n)}(x+y)^2 - \eta - 2p_k^{(n)}(y)^2 \geq 2p_k^{(n)}(x)^2 - (\beta_{nk}+1)\eta,\end{aligned}$$

so

$$\begin{aligned}\sum_{i\in J}\|Tx_i\|_i^2 \leq p_{Jk}(x)^2 \leq p_k^{(n)}(x)^2 &\leq p_{Lk}(x)^2 + \tfrac{1}{2}(\beta_{nk}+1)\eta\\ &\leq \sum_{i\in L}\|Tx_i\|_i^2 + \tfrac{2^n(Mn+1)}{k}\|x\|^2 + \tfrac{1}{2}(\beta_{nk}+1)\eta\\ &< \sum_{i\in L}\|Tx_i\|_i^2 + \alpha_1^2 - \alpha_0^2.\end{aligned}$$

Since $\#(L) = \#(J)$ and

$$\|Tx_i\|_i^2 \leq \alpha_0^2 < \alpha_1^2 \leq \|Tx_j\|_j^2$$

whenever $j \in J$ and $i \in I \setminus J$, we must actually have $L = J$. In particular, $K \subseteq L$. But this means that (by 467C(c-ii) again)

$$q_{\|\,\|_i}(T_ix, T_iy) \leq q_{p_{Lk}}(x,y) \leq (\beta_{nk}+1)\eta$$

and (by the choice of η) $\|T_ix - T_iy\| \leq \frac{\epsilon}{1+4n}$ for every $i \in K$, so that $\|\sum_{i\in K} T_ix - \sum_{i\in K} T_iy\| \leq \frac{1}{4}\epsilon$.

The last element we need is that, setting $\tilde{p}(z) = \frac{1}{\sqrt{k}}\|z - \sum_{i\in K} T_iz\|$, $\tilde{p}$ is a seminorm on X and is one of the constituents of p_{Lk}; so that

$$\begin{aligned}\tfrac{1}{k}(\|x - \sum_{i\in K} T_ix\| - \|y - \sum_{i\in K} T_iy\|)^2 \leq q_{\tilde{p}}(x,y) &\leq q_{p_{Lk}}(x,y)\\ &\leq (\beta_{nk}+1)\eta \leq \frac{\epsilon^2}{16k},\end{aligned}$$

and $\big|\|x - \sum_{i\in K} T_ix\| - \|y - \sum_{i\in K} T_iy\|\big| \leq \frac{1}{4}\epsilon$. This means that

$$\|y - \textstyle\sum_{i\in K} T_iy\| \leq \frac{1}{4}\epsilon + \|x - \sum_{i\in K} T_ix\| \leq \frac{1}{2}\epsilon.$$

Putting these together,

$$\|x - y\| \leq \|x - \textstyle\sum_{i\in K} T_ix\| + \sum_{i\in K}\|T_ix - T_iy\| + \|y - \sum_{i\in K} T_iy\| \leq \epsilon.$$

And this is true whenever $q_{\|\,\|'}(x,y) \leq \eta$. As x and ϵ are arbitrary, $\|\,\|'$ is locally uniformly rotund. **Q**

467G Theorem Let X be a Banach space. Suppose that there are an ordinal ζ and a family $\langle P_\xi\rangle_{\xi\leq\zeta}$ of bounded linear operators from X to itself such that

(i) if $\xi \leq \eta \leq \zeta$ then $P_\xi P_\eta = P_\eta P_\xi = P_\xi$;

(ii) $P_0(x) = 0$ and $P_\zeta(x) = x$ for every $x \in X$;

(iii) if $\xi \leq \zeta$ is a non-zero limit ordinal, then $\lim_{\eta\uparrow\xi} P_\eta(x) = P_\xi(x)$ for every $x \in X$;

(iv) if $\xi < \zeta$ then $X_\xi = \{(P_{\xi+1} - P_\xi)(x) : x \in X\}$ has an equivalent locally uniformly rotund norm.

Then X has an equivalent locally uniformly rotund norm.

Remark A family $\langle P_\xi\rangle_{\xi\leq\zeta}$ satisfying (i), (ii) and (iii) here is called a **projectional resolution of the identity**.

proof For $\xi < \zeta$ set $T_\xi = P_{\xi+1} - P_\xi$. From condition (i) we see easily that $T_\xi T_\eta = T_\xi$ if $\xi = \eta$, 0 otherwise; and that $T_\xi P_\eta = T_\xi$ if $\xi < \eta$, 0 otherwise.

I seek to show that the conditions of 467F are satisfied by $\langle T_\xi\rangle_{\xi<\zeta}$. Condition (i) of 467F is just condition (iv) here. Let Z be the set of those $x \in X$ for which conditions (ii) and (iii) of 467F are satisfied; that is,

for each $\epsilon > 0$ there is a finite set $J \subseteq \zeta$ such that $\|x - \sum_{\xi\in J} T_\xi x\| \leq \epsilon$, and $\{\xi : \|T_\xi x\| \geq \epsilon\}$ is finite.

Then Z is a linear subspace of X. For $\xi \leq \zeta$, set $Y_\xi = P_\xi[X]$. Then $Y_\xi \subseteq Z$. **P** Induce on ξ. Since $Y_0 = \{0\}$, the induction starts. For the inductive step to a successor ordinal $\xi + 1 \leq \zeta$, $Y_{\xi+1} = Y_\xi + X_\xi \subseteq Z$. For the inductive step to a non-zero limit ordinal $\xi \leq \zeta$, given $x \in Y_\xi$ and $\epsilon > 0$, we know that there is a $\xi' < \xi$ such that $\|P_\eta x - P_\xi x\| \leq \frac{1}{3}\epsilon$ whenever $\xi' \leq \eta \leq \xi$. So $\|T_\eta x\| \leq \frac{2}{3}\epsilon$ whenever $\xi' \leq \eta < \xi$, and

$$\{\eta : \|T_\eta x\| \geq \epsilon\} = \{\eta : \eta < \xi',\ \|T_\eta x\| \geq \epsilon\} = \{\eta : \|T_\eta P_{\xi'} x\| \geq \epsilon\}$$

is finite, by the inductive hypothesis. Moreover, there is a finite set $J \subseteq \xi'$ such that $\|P_{\xi'}x - \sum_{\eta\in J} T_\eta P_{\xi'} x\| \leq \frac{2}{3}\epsilon$, and now $\|x - \sum_{\eta\in J} T_\eta x\| \leq \epsilon$. As x and ϵ are arbitrary, $Y_\xi \subseteq Z$. **Q**

In particular, $X = Y_\zeta \subseteq Z$ and conditions (ii) and (iii) of 467F are satisfied. So 467F gives the result.

467H Definitions (a) A topological space X is **K-countably determined** or a **Lindelöf-Σ** space if there are a subset A of $\mathbb{N}^{\mathbb{N}}$ and an usco-compact relation $R \subseteq A \times X$ such that $R[A] = X$. Observe that all K-analytic Hausdorff spaces (§422) are K-countably determined.

(b) A normed space X is **weakly K-countably determined** if it is K-countably determined in its weak topology.

(c) Let X be a normed space and Y, W closed linear subspaces of X, X^* respectively. I will say that (Y, W) is a **projection pair** if $X = Y \oplus W^\circ$ and $\|y + z\| \geq \|y\|$ for every $y \in Y$, $z \in W^\circ$, where

$$W^\circ = \{z : z \in X,\ f(z) \leq 1 \text{ for every } f \in W\} = \{z : z \in X,\ f(z) = 0 \text{ for every } f \in W\}.$$

467I Lemma (a) If X is a weakly K-countably determined normed space, then any closed linear subspace of X is weakly K-countably determined.

(b) If X is a weakly K-countably determined normed space, Y is a normed space, and $T : X \to Y$ is a continuous linear surjection, then Y is weakly K-countably determined.

(c) If X is a Banach space and $Y \subseteq X$ is a dense linear subspace which is weakly K-countably determined, then X is weakly K-countably determined.

proof (a) Let $A \subseteq \mathbb{N}^{\mathbb{N}}$, $R \subseteq A \times X$ be such that R is usco-compact (for the weak topology on X) and $R[A] = X$. Let Y be a (norm-)closed linear subspace of X; then Y is closed for the weak topology (3A5Ee). Also the weak topology on Y is just the subspace topology induced by the weak topology of X (4A4Ea). Set $R' = R \cap (A \times Y)$. Then R' is usco-compact whether regarded as a subset of $A \times X$ or as a subset of $A \times Y$ (422Da, 422Db, 422Dg). Since $Y = R'[A]$, Y is weakly K-countably determined.

(b) Let $A \subseteq \mathbb{N}^{\mathbb{N}}$, $R \subseteq A \times X$ be such that R is usco-compact for the weak topology on X and $R[A] = X$. Because T is continuous for the weak topologies on X and Y (3A5Ec),

$$R_1 = \{(\phi, y)\text{: there is some } x \in X \text{ such that } (\phi, x) \in R \text{ and } Tx = y\}$$

is usco-compact in $A \times Y$ (422Db, 422Df). Also $R_1[A] = T[R[A]] = Y$. So Y is weakly K-countably determined.

(c) Let $A \subseteq \mathbb{N}^{\mathbb{N}}$, $R \subseteq A \times Y$ be such that R is usco-compact (for the weak topology on Y) and $R[A] = Y$. Then, as in (a), R is usco-compact when regarded as a subset of $A \times X$. By 422Dd, the set

$$R_1 = \{(\langle\phi_n\rangle_{n\in\mathbb{N}}, \langle y_n\rangle_{n\in\mathbb{N}}) : (\phi_n, y_n) \in R \text{ for every } n \in \mathbb{N}\}$$

is usco-compact in $A^{\mathbb{N}} \times Y^{\mathbb{N}}$. Now examine

$$S = \{(\langle y_n\rangle_{n\in\mathbb{N}}, x) : x \in X,\ y_n \in Y \text{ and } \|y_n - x\| \leq 2^{-n} \text{ for every } n \in \mathbb{N}\}.$$

Then S is usco-compact in $Y^{\mathbb{N}} \times X$. **P** (Remember that we are using weak topologies on X and Y throughout.) If $\boldsymbol{y} = \langle y_n\rangle_{n\in\mathbb{N}}$ is a sequence in Y and $(\boldsymbol{y}, x) \in S$, then $x = \lim_{n\to\infty} y_n$; so $S[\{\boldsymbol{y}\}]$ has at most one member and is certainly compact. Let $F \subseteq X$ be a weakly closed set and $\boldsymbol{y} \in Y^{\mathbb{N}} \setminus S^{-1}[F]$.

case 1 If there are m, $n \in \mathbb{N}$ such that $\|y_m - y_n\| > 2^{-m} + 2^{-n}$, let $f \in Y^*$ be such that $\|f\| \leq 1$ and $f(y_m - y_n) > 2^{-m} + 2^{-n}$. Then $G = \{\boldsymbol{z} : f(z_m - z_n) > 2^{-m} + 2^{-n}\}$ is an open set in $Y^{\mathbb{N}}$ containing $\boldsymbol{y}$ and disjoint from $S^{-1}[F]$, because $S[G]$ is empty.

case 2 Otherwise, $\boldsymbol{y}$ is a Cauchy sequence and (because X is a Banach space) has a limit $x \in X$, which does not belong to F. Let $\delta > 0$ and $f_0, \dots, f_r \in X^*$ be such that $\{w : |f_i(w) - f_i(x)| \leq \delta \text{ for every } i \leq r\}$ does not meet F. Let $n \in \mathbb{N}$ be such that $2^{-n}\|f_i\| \leq \frac{1}{3}\delta$ for every $i \leq r$. Then $G = \{\boldsymbol{z} : |f_i(z_n) - f_i(y_n)| < \frac{1}{3}\delta$ for every $i \leq r\}$ is an open set in $Y^{\mathbb{N}}$ containing Y. If $\boldsymbol{z} \in G$ and $(\boldsymbol{z}, w) \in S$, then $\|z_n - w\| \leq 2^{-n}$ so

$$\begin{aligned}|f_i(w) - f_i(x)| &\leq |f_i(w) - f_i(z_n)| + |f_i(z_n) - f_i(y_n)| + |f_i(y_n) - f_i(x)| \\ &\leq 2^{-n}\|f_i\| + \frac{1}{3}\delta + 2^{-n}\|f_i\| \leq \delta\end{aligned}$$

for every $i \leq r$, and $w \notin F$. Thus again $G \cap S^{-1}[F]$ is empty.

This shows that there is always an open set containing y and disjoint from $S^{-1}[F]$. As y is arbitrary, $S^{-1}[F]$ is closed. As F is arbitrary, S is usco-compact. **Q**

It follows that $SR_1 \subseteq A^{\mathbb{N}} \times X$ is usco-compact (422Df), while

$$(SR_1)[A^{\mathbb{N}}] = S[R_1[A^{\mathbb{N}}]] = S[Y^{\mathbb{N}}] = X$$

because Y is dense in X. Finally, $A^{\mathbb{N}}$ is homeomorphic to a subset of $\mathbb{N}^{\mathbb{N}}$ because it is a subspace of $(\mathbb{N}^{\mathbb{N}})^{\mathbb{N}} \cong \mathbb{N}^{\mathbb{N}}$. So X is weakly K-countably determined.

467J Lemma Let X be a weakly K-countably determined Banach space. Then there is a family $\mathcal{M}$ of subsets of $X \cup X^*$ such that

(i) whenever $B \subseteq X \cup X^*$ there is an $M \in \mathcal{M}$ such that $B \subseteq M$ and $\#(M) \leq \max(\omega, \#(B))$;

(ii) whenever $\mathcal{M}' \subseteq \mathcal{M}$ is upwards-directed, then $\bigcup \mathcal{M}' \in \mathcal{M}$;

(iii) whenever $M \in \mathcal{M}$ then $(\overline{M \cap X}, \overline{M \cap X^*})$ (where the closures are taken for the norm topologies) is a projection pair of subspaces of X and X^*.

proof (a) Let $A \subseteq \mathbb{N}^{\mathbb{N}}$, $R \subseteq A \times X$ be such that R is usco-compact in $A \times X$ and $R[A] = X$. Set $S = \bigcup_{n \in \mathbb{N}} \mathbb{N}^n$ and for $\sigma \in S$ set $F_\sigma = R[I_\sigma]$, where $I_\sigma = \{\phi : \sigma \subseteq \phi \in \mathbb{N}^{\mathbb{N}}\}$; set $S_0 = \{\sigma : \sigma \in S, F_\sigma \neq \emptyset\}$.

Let $\mathcal{M}$ be the family of those sets $M \subseteq X \cup X^*$ such that (α) whenever $x, y \in M \cap X$ and $q \in \mathbb{Q}$ then $x + y$ and qx belong to M (β) whenever $f, g \in M \cap X^*$ and $q \in \mathbb{Q}$ then $f + g$ and qf belong to M (γ) $\|x\| = \max\{f(x) : f \in M \cap X^*, \|f\| \leq 1\}$ for every $x \in M \cap X$ (δ) $\sup_{x \in F_\sigma} f(x) = \sup_{x \in F_\sigma \cap M} f(x)$ for every $f \in M \cap X^*$, $\sigma \in S_0$.

(b) For each $x \in X$, choose $h_x \in X^*$ such that $\|h_x\| \leq 1$ and $h_x(x) = \|x\|$; for each $f \in X^*$ and $\sigma \in S_0$ choose a countable set $C_{f\sigma} \subseteq F_\sigma$ such that $\sup\{f(x) : x \in C_{f\sigma}\} = \sup\{f(x) : x \in F_\sigma\}$. Given $B \subseteq X$, define $\langle B_n \rangle_{n \in \mathbb{N}}$ by setting

$$\begin{aligned}B_{n+1} = B_n &\cup \{x + y : x, y \in B_n \cap X\} \cup \{qx : q \in \mathbb{Q}, x \in B_n \cap X\} \\ &\cup \{f + g : f, g \in B_n \cap X\} \cup \{qf : q \in \mathbb{Q}, f \in B_n \cap X\} \\ &\cup \{h_x : x \in B_n \cap X\} \cup \bigcup \{C_{f\sigma} : f \in B_n \cap X^*, \sigma \in S_0\},\end{aligned}$$

for each $n \in \mathbb{N}$. Then $M = \bigcup_{n \in \mathbb{N}} B_n$ belongs to $\mathcal{M}$ and has cardinal at most $\max(\omega, \#(B))$.

(c) The definition of $\mathcal{M}$ makes it plain that if $\mathcal{M}' \subseteq \mathcal{M}$ is upwards-directed then $\bigcup \mathcal{M}'$ belongs to $\mathcal{M}$.

(d) Now take $M \in \mathcal{M}$ and set $Y = \overline{M \cap X}$, $W = \overline{M \cap X^*}$. These are linear subspaces (2A5Ec). If $y \in M \cap X$ and $z \in W^\circ$, then there is an $f \in M \cap X^*$ such that $\|f\| \leq 1$ and $f(y) = \|y\|$, so that

$$\|y + z\| \geq f(y + z) = f(y) = \|y\|.$$

Because the function $y \mapsto \|y+z\| - \|y\|$ is continuous, $\|y+z\| \geq \|y\|$ for every $y \in Y$ and $z \in W^\circ$. In particular, if $y \in Y \cap W^\circ$, $\|y\| \leq \|y - y\| = 0$ and $y = 0$, so $Y + W^\circ = Y \oplus W^\circ$. If $x \in \overline{Y + W^\circ}$, then there are sequences $\langle y_n \rangle_{n \in \mathbb{N}}$ in Y and $\langle z_n \rangle_{n \in \mathbb{N}}$ in W° such that $x = \lim_{n \to \infty} y_n + z_n$; now $\|y_m - y_n\| \leq \|(y_m + z_m) - (y_n + z_n)\| \to 0$ as $n \to \infty$, so (because X is a Banach space) $\langle y_n \rangle_{n \in \mathbb{N}}$ is convergent to y say; in this case, $y \in Y$ and $x - y = \lim_{n \to \infty} z_n$ belongs to W°, so $x \in Y + W^\circ$. This shows that $Y \oplus W^\circ$ is a closed linear subspace of X.

(e) **?** Suppose, if possible, that $Y \oplus W^\circ \neq X$. Then there is an $x_0 \in X \setminus (Y \oplus W^\circ)$. By 4A4Eb, there is an $f \in X^*$ such that $f(x_0) > 0$ and $f(y) = f(z) = 0$ whenever $y \in Y$ and $z \in W^\circ$; multiplying f by a scalar if necessary, we can arrange that $f(x_0) = 1$. By 4A4Eg, f belongs to the weak* closure of W in X^*.

Let $\phi \in A$ be such that $(\phi, x_0) \in R$. Then $K = R[\{\phi\}]$ is weakly compact. Now the weak* closure of W is also its closure for the Mackey topology of uniform convergence on weakly compact subsets of X (4A4F). So there is a $g \in W$ such that $|g(x) - f(x)| \leq \frac{1}{7}$ for every $x \in K$. Next, because K is bounded, and g belongs to the norm closure of $M \cap X^*$, there is an $h \in M \cap X^*$ such that $|h(x) - g(x)| \leq \frac{1}{7}$ for every $x \in K$. This means that $|h(x) - f(x)| \leq \frac{2}{7}$ for every $x \in K$, and K is included in the weakly open set $G = \{x : h(x) - f(x) < \frac{3}{7}\}$, that is, ϕ does not belong to $R^{-1}[X \setminus G]$, which is relatively closed in A, because R is usco-compact regarded as a relation between A and X with the weak topology. There is therefore a $\sigma \in S$ such that $\phi \in I_\sigma$ and $I_\sigma \cap R^{-1}[X \setminus G] = \emptyset$, that is, $F_\sigma \subseteq G$. In this case, $x_0 \in F_\sigma$, so $\sigma \in S_0$, while $h(x) - f(x) < \frac{3}{7}$ for every $x \in F_\sigma$. But, because $M \in \mathcal{M}$, there is a $y \in M \cap X \cap F_\sigma$ such that $h(y) \geq h(x_0) - \frac{1}{7}$, and as $y \in Y$ we must now have

$$\begin{aligned} 0 = f(y) &= h(y) - (h(y) - f(y)) > h(x_0) - \frac{1}{7} - \frac{3}{7} \\ &= f(x_0) - (f(x_0) - h(x_0)) - \frac{4}{7} \geq 1 - \frac{3}{7} - \frac{4}{7} = 0, \end{aligned}$$

which is absurd. **X**

Thus $X = Y \oplus W^\circ$ and (Y, W) is a projection pair. This completes the proof.

467K Theorem Let X be a weakly K-countably determined Banach space. Then it has an equivalent locally uniformly rotund norm.

proof Since the completion of X is weakly K-countably determined (467Ic), we may suppose that X is complete. The proof proceeds by induction on the weight of X.

(a) The induction starts by observing that if $w(X) \leq \omega$ then X is separable (4A2Li) so has an equivalent locally uniformly rotund norm by 467E.

(b) So let us suppose that $w(X) = \kappa > \omega$ and that any weakly K-countably determined Banach space of weight less than κ has an equivalent locally uniformly rotund norm.

Let $\mathcal{M}$ be a family of subsets of $X \cup X^*$ as in 467J. Then there is a non-decreasing family $\langle M_\xi \rangle_{\xi \leq \kappa}$ in $\mathcal{M}$ such that $\#(M_\xi) \leq \max(\omega, \#(\xi))$ for every $\xi \leq \kappa$, M_κ is dense in X, and $M_\xi = \bigcup_{\eta < \xi} M_\eta$ for every limit ordinal $\xi \leq \kappa$. **P** By 4A2Li, there is a dense subset of X of cardinal κ; enumerate it as $\langle x_\xi \rangle_{\xi < \kappa}$. Choose M_ξ inductively, as follows. $M_0 = \emptyset$. GIven M_ξ with $\#(M_\xi) \leq \max(\omega, \#(\xi))$, then by 467J(i) there is an $M_{\xi+1} \in \mathcal{M}$ such that $M_{\xi+1} \supseteq M_\xi \cup \{x_\xi\}$ and

$$\#(M_{\xi+1}) \leq \max(\omega, \#(M_\xi \cup \{x_\xi\}) \leq \max(\omega, \#(\xi + 1)).$$

Given that $\langle M_\eta \rangle_{\eta < \xi}$ is a non-decreasing family in $\mathcal{M}$ with $\#(M_\eta) \leq \max(\omega, \#(\eta))$ for every $\eta < \xi$, set $M_\xi = \bigcup_{\eta < \xi} M_\eta$; then 467J(ii) tells us that $M_\xi \in \mathcal{M}$, while $\#(M_\xi) \leq \max(\omega, \#(\xi))$, as required by the inductive hypothesis. **Q**

At the end of the induction, $M_\kappa \supseteq \{x_\xi : \xi < \kappa\}$ will be dense in X.

(c) For each $\xi < \kappa$, set $Y_\xi = \overline{M_\xi \cap X}$, $W_\xi = \overline{M_\xi \cap X^*}$. Then (Y_ξ, W_ξ) is a projection pair, by 467J(iii). Since $X = Y_\xi \oplus W_\xi^\circ$, we have a projection $P_\xi : X \to Y_\xi$ defined by saying that $P_\xi(y + z) = y$ whenever $y \in Y_\xi$ and $z \in W_\xi^\circ$. Now $P_\xi P_\eta = P_\eta P_\xi = P_\xi$ whenever $\xi \leq \eta$. **P** The point is that $Y_\xi \subseteq Y_\eta$ and $W_\xi \subseteq W_\eta$, so $W_\eta^\circ \subseteq W_\xi^\circ$. If $x \in X$, express it as $y + z_1$ where $y \in Y_\xi$ and $z_1 \in W_\xi^\circ$, and express z_1 as $y' + z$ where $y' \in Y_\eta$ and $z' \in W_\eta^\circ$. Then

$$P_\xi x = y \in Y_\xi \subseteq Y_\eta$$

so $P_\eta P_\xi x = P_\xi x$. On the other hand, $x = y + y' + z$, $y + y' \in Y_\eta$ and $z \in W_\eta^\circ$, so $P_\eta x = y + y'$; and as $y' = z_1 - z$ belongs to W_ξ°, $P_\xi(y + y') = y$, so $P_\xi P_\eta x = P_\xi x$. **Q**

Note that the condition

$$\|y + z\| \geq \|y\| \text{ whenever } y \in Y_\xi,\ z \in W_\xi^\circ$$

ensures that $\|P_\xi\| \leq 1$ for every ξ.

Next, if $\xi \leq \kappa$ is a non-zero limit ordinal, $P_\xi x = \lim_{\eta \uparrow \xi} P_\eta x$. **P** We know that

$$P_\xi x \in Y_\xi = \overline{M_\xi \cap X} = \overline{\bigcup_{\eta<\xi} M_\eta \cap X}.$$

So, given $\epsilon > 0$, there is an $x' \in \bigcup_{\eta<\xi} M_\eta$ such that $\|P_\xi x - x'\| \leq \frac{1}{2}\epsilon$. Let $\eta < \xi$ be such that $x' \in M_\eta$. If $\eta \leq \eta' \leq \xi$, then

$$\|P_\xi x - P_{\eta'} x\| = \|P_\xi(P_\xi x - x') - P_{\eta'}(P_\xi x - x')\|$$

(because $x' \in Y_\eta$, so $P_\xi x' = P_{\eta'} x' = x'$)

$$\leq 2\|P_\xi x - x'\| \leq \epsilon.$$

As ϵ is arbitrary, $P_\xi x = \lim_{\eta\uparrow\xi} P_\eta x$. **Q**

(d) Now observe that every Y_ξ is weakly K-countably determined (467Ia), while $w(Y_\xi) \leq \max(\omega, \#(\xi)) < \kappa$ for every $\xi < \kappa$ (using 4A2Li, as usual). So the inductive hypothesis tells us that $Y_\xi = P_\xi[X]$ has an equivalent locally uniformly rotund norm for every $\xi < \kappa$. By 467G, $X = P_\kappa[X]$ has an equivalent locally uniformly rotund norm. Thus the induction proceeds.

467L Weakly compactly generated Banach spaces The most important class of weakly K-countably determined spaces is the following. A normed space X is **weakly compactly generated** if there is a sequence $\langle K_n\rangle_{n\in\mathbb{N}}$ of weakly compact subsets of X such that $\bigcup_{n\in\mathbb{N}} K_n$ is dense in X.

467M Proposition (Talagrand 75) A weakly compactly generated Banach space is weakly K-countably determined.

proof Let X be a Banach space with a sequence $\langle K_n\rangle_{n\in\mathbb{N}}$ of weakly compact subsets of X such that $\bigcup_{n\in\mathbb{N}} K_n$ is dense in X. Set

$$L_n = \{\textstyle\sum_{i=0}^n \alpha_i x_i : |\alpha_i| \leq n,\ x_i \in \bigcup_{j\leq n} K_j \text{ for every } i \leq n\}$$

for $n \in \mathbb{N}$. Then every L_n is weakly compact, and $Y = \bigcup_{n\in\mathbb{N}} L_n$ is a linear subspace of X including $\bigcup_{n\in\mathbb{N}} K_n$, therefore dense. Now Y is a countable union of weakly compact sets, therefore K-analytic for its weak topology (422Gc, 422Hc); in particular, it is weakly K-countably determined. By 467Ic, X is weakly K-countably determined.

467N Theorem Let X be a Banach lattice with an order-continuous norm (§354). Then it has an equivalent locally uniformly rotund norm.

proof (a) Consider first the case in which X has a weak order unit e. Then the interval $[0, e]$ is weakly compact. **P** We have $X^* = X^\times$ and $X^{**} = X^{\times\sim}$ (356D). The canonical identification of X with its image in X^{**} is an order-continuous Riesz homomorphism from X onto a solid order-dense Riesz subspace of $X^{\times\times}$ (356I) and therefore of $X^{\times\sim} = X^{**}$. In particular, $[0, e] \subseteq X$ is matched with an interval $[0, \hat{e}] \subseteq X^{**}$. But $[0, \hat{e}] = \{\theta : \theta \in X^{**},\ 0 \leq \theta(f) \leq f(e) \text{ for every } f \in (X^*)^+\}$ is weak*-closed and norm-bounded in X^{**}, therefore weak*-compact; as the weak* topology on X^{**} corresponds to the weak topology of X, $[0, e]$ is weakly compact. **Q**

Now, for each $n \in \mathbb{N}$, $K_n = [-ne, ne] = n[0, e] - n[0, e]$ is weakly compact. If $x \in X^+$, then $\langle x \wedge ne\rangle_{n\in\mathbb{N}}$ converges to X, because the norm of X is order-continuous; so for any $x \in X$, $\langle x^+ \wedge ne - x^- \wedge ne\rangle_{n\in\mathbb{N}}$ converges to x. Thus $\bigcup_{n\in\mathbb{N}} K_n$ is dense in X and X is weakly compactly generated. By 467M and 467K, X has an equivalent locally uniformly rotund norm.

(b) For the general case, let $\langle x_i\rangle_{i\in I}$ be a maximal disjoint family in X^+. For each $i \in I$ let X_i be the band in X generated by x_i, and $T_i : X \to X_i$ the band projection onto X_i (354Ee, 353Hb). Then $\langle T_i\rangle_{i\in I}$ satisfies the conditions of 467F. **P** (i) Each T_i is a continuous linear operator because the given norm $\|\ \|$ of X is a Riesz norm. Next, each X_i has a weak order unit x_i, and the norm on X_i is order-continuous, so (a) tells us that there is an equivalent locally uniformly rotund norm on $X_i = T_i[X]$. (ii) If $x \in X$, set $x' = \sup_{i\in I} T_i|x|$; then $(|x| - x') \wedge x_i = 0$ for every i, so, by the maximality of $\langle x_i\rangle_{i\in I}$, $x' = |x|$. If $\epsilon > 0$ then, because the norm of X is order-continuous, there is a finite $J \subseteq I$ such that

$$\|x - \textstyle\sum_{j\in J} T_i x\| = \|x' - \sup_{j\in J} T_i|x|\| \leq \epsilon.$$

Moreover, if $i \in I \setminus J$, then

$$\|T_i x\| \leq \|x - \sum_{j \in J} T_j x\| \leq \epsilon.$$

Thus conditions (ii) and (iii) of 467F are satisfied. **Q**

Accordingly 467F tells us that X has an equivalent locally uniformly rotund norm.

467O Eberlein compacta: Definition A topological space K is an **Eberlein compactum** if it is homeomorphic to a weakly compact subset of a Banach space.

467P Proposition Let K be a compact Hausdorff space.

(a) The following are equiveridical:

(i) K is an Eberlein compactum;

(ii) there is a set $L \subseteq C(K)$, separating the points of K, which is compact for the topology of pointwise convergence.

(b) Suppose that K is an Eberlein compactum.

(i) K has a σ-isolated network, so is hereditarily weakly θ-refinable.

(ii) (SCHACHERMAYER 77) If $w(K)$ is measure-free, K is a Radon space.

proof (a)(i)⇒(ii) If K is an Eberlein compactum, we may suppose that it is a weakly compact subset of a Banach space X. Set $L = \{f \restriction K : f \in X^*, \|f\| \leq 1\}$; since the map $f \mapsto f \restriction K : X^* \to C(K)\}$ is continuous for the weak* topology of X^* and the topology $\mathfrak{T}_p$ of pointwise convergence on $C(K)$, L is $\mathfrak{T}_p$-compact; and L separates the points of K because X^* separates the points of X.

(ii)⇒(i) If $L \subseteq C(K)$ is $\mathfrak{T}_p$-compact and separates the points of K, set $L_n = \{f : f \in L, \|f\|_\infty \leq n\}$ for each $n \in \mathbb{N}$. Then L_n is $\mathfrak{T}_p$-compact for each n. Set $L' = \{0\} \cup \bigcup_{n \in \mathbb{N}} 2^{-n} L_n$; then $L' \subseteq C(K)$ is norm-bounded and $\mathfrak{T}_p$-compact and separates the points of K. Now define $x \mapsto \hat{x} : K \to \mathbb{R}^{L'}$ by setting $\hat{x}(f) = f(x)$ for $x \in K$, $f \in L'$. Then $\hat{x} \in C(L')$ for every x and $x \mapsto \hat{x}$ is continuous for the given topology of K and the topology of pointwise convergence on $C(L')$; so the image $\hat{K} = \{\hat{x} : x \in K\}$ is $\mathfrak{T}_p$-compact. Since it is also bounded, it is weakly compact (462E). But $x \mapsto \hat{x}$ is injective, because L' separates the points of K; so K is homeomorphic to $\hat{K}$, and is an Eberlein compactum.

(b) Again suppose K is actually a weakly compact subset of a Banach space X. As in 467M, set $L_n = \{\sum_{i=0}^n \alpha_i x_i : |\alpha_i| \leq n, x_i \in K \text{ for every } i \leq n\}$ for each $n \in \mathbb{N}$. Then $Y = \overline{\bigcup_{n \in \mathbb{N}} L_n}$ is a weakly compactly generated Banach space. (I am passing over the trivial case $K = \emptyset$.) So Y has an equivalent locally uniformly rotund norm (467M, 467K), which is a Kadec norm (467B), and Y, with the weak topology, has a σ-isolated network (466Eb). It follows at once that K has a σ-isolated network (4A2B(a-ix)), so is hereditarily weakly θ-refinable (438Ld); and if $w(K)$ is measure-free, K is Borel-measure-complete (438M), therefore Radon (434Jf, 434Ka).

467X Basic exercises (a) (i) Show that a continuous image of a K-countably determined space is K-countably determined. (ii) Show that the product of a sequence of K-countably determined spaces is K-countably determined. (iii) Show that any K-countably determined topological space is Lindelöf. (*Hint*: 422De.) (iv) Show that any Souslin-F subset of a K-countably determined topological space is K-countably determined. (*Hint*: 422Hc.)

(b) Let X be a σ-compact Hausdorff space. Show that a subspace Y of X is K-countably determined iff there is a countable family $\mathcal{K}$ of compact subsets of X such that $\bigcap\{K : x \in K \in \mathcal{K}\} \subseteq Y$ for every $x \in Y$.

(c) Show that if X and Y are weakly K-countably determined normed spaces, then $X \times Y$, with an appropriate norm, is weakly K-countably determined.

(d) Show that a normed space X is weakly compactly generated iff there is a weakly compact set $K \subseteq X$ such that the linear subspace of X generated by K is dense in X.

(e) Show that any separable normed space is weakly compactly generated.

(f) Show that any reflexive Banach space is weakly compactly generated.

>(g) Show that if X is a weakly compactly generated Banach space, then it is K-analytic in its weak topology. (*Hint*: in 467M, use the proof of 467Ic.)

(h) Show that if X is a Banach space and there is a set $A \subseteq X$ such that A is K-countably determined for the weak topology and the linear subspace generated by A is dense, then X is weakly K-countably determined.

(i) Show that the one-point compactification of any discrete space is an Eberlein compactum.

467Y Further exercises (a) Let $\langle X_n \rangle_{n \in \mathbb{N}}$ be a sequence of weakly K-countably determined normed spaces. Investigate normed subspaces of $\prod_{n \in \mathbb{N}} X_n$ which will be weakly K-countably determined.

(b) (i) Show that if (Ω, Σ, μ) is a probability space, then $L^1(\mu)$ has a locally uniformly rotund Riesz norm. (*Hint*: apply the construction of 467D with $Y = L^2(\mu)$ and T the identity operator; show that all the norms p_n are Riesz norms.) (ii) Show that if X is any L-space then it has a locally uniformly rotund Riesz norm. (*Hint*: apply the construction of 467F/467N, noting that if the T_i in 467F are band projections and $\| \|$ and all the $\| \|_i$ are Riesz norms, then all the norms in the proof of 467F are Riesz norms.)

467 Notes and comments The purpose of this section has been to give an idea of the scope of Proposition 466F. 'Local uniform rotundity' has an important place in the geometrical theory of Banach spaces, but for the many associated ideas I refer you to Deville Godefroy & Zizler 93. From our point of view, Theorem 467E is therefore purely accessory, since we know by different arguments that on separable Banach spaces the weak and norm topologies have the same Borel σ-algebras (4A3V). We need it to provide the first step in the inductive proof of 467K.

Since the concept of 'K-analytic' space is one of the fundamental ideas of Chapter 43, it is natural here to look at 'K-countably determined' spaces, especially as many of the ideas of §422 are directly applicable (467Xa). But the goal of this part of the argument is Schachermayer's theorem 467P(b-ii), which uses 'weakly compactly generated' spaces (467L). 'Eberlein compacta' are of great interest in other ways; they are studied at length in Arkhangel'skii 92.

I mention order-continuous norms here (467N) because they are prominent in the theory of Banach lattices in Volume 3. Note that the methods here do *not* suffice in general to arrange that the locally uniformly rotund norm found on X is a Riesz norm; though see 467Yb. It is in fact the case that every Banach lattice with an order-continuous norm has an equivalent locally uniformly rotund Riesz norm, but this requires further ideas (see Davis Ghoussoub & Lindenstrauss 81).

Chapter 47

Geometric measure theory

I offer a chapter on geometric measure theory, continuing from Chapter 26. The greater part of it is directed specifically at a version of the Divergence Theorem (475N), and I do not attempt to provide a balanced view of the subject, for which I must refer you to Mattila 95, Evans & Gariepy 92 and Federer 69. However §472, at least, deals with something which must be central to any approach, Besicovitch's Density Theorem for Radon measures on $\mathbb{R}^r$. In §473 I examine Lipschitz functions, and give crude forms of some fundamental ineqalities relating integrals $\int \|\operatorname{grad} f\| d\mu$ with other measures of the variation of a function f. In §474 I introduce perimeter measures λ_E^∂ and outward-normal functions ψ_E as those for which the Divergence Theorem, in the form $\int_E \operatorname{div} \phi \, d\mu = \int \phi \cdot \psi_E \, d\lambda_E^\partial$, will be valid, and give the geometric description of $\psi_E(x)$ as the Federer exterior normal to E at x. In §475 I show that λ_E^∂ can be identified with normalized Hausdorff $r-1$-dimensional measure on the essential boundary of E.

§471 is devoted to Hausdorff measures on general metric spaces, extending the ideas introduced in §264 for Euclidean space, up to basic results on densities (471P) and Howroyd's theorem (471S). In §476 I turn to a different topic, the problem of finding the subsets of $\mathbb{R}^r$ on which Lebesgue measure is most 'concentrated' in some sense. I present a number of classical results, the deepest being the Isoperimetric Theorem (476L): among sets with a given measure, those with the smallest perimeters are the balls.

471 Hausdorff measures

I begin the chapter by returning to a class of measures which we have not examined since Chapter 26. The primary importance of these measures is in studying the geometry of Euclidean space; in §265 I looked briefly at their use in describing surface measures, which will reappear in §475. Hausdorff measures are also one of the basic tools in the study of fractals, but for such applications I must refer you to Falconer 90 and Mattila 95. All I shall attempt to do here is to indicate some of the principal ideas which are applicable to general metric spaces, and to look at some special properties of Hausdorff measures related to the concerns of this chapter and of §261.

471A Definition Let (X, ρ) be a metric space and $r \in]0, \infty[$. For $\delta > 0$ and $A \subseteq X$, set

$$\theta_{r\delta} A = \inf\{\sum_{n=0}^{\infty} (\operatorname{diam} D_n)^r : \langle D_n \rangle_{n\in\mathbb{N}} \text{ is a sequence of subsets of } X \text{ covering } A, \operatorname{diam} D_n \leq \delta \text{ for every } n \in \mathbb{N}\}.$$

(As in §264, take $\operatorname{diam} \emptyset = 0$ and $\inf \emptyset = \infty$.) It will be useful to note that every $\theta_{r\delta}$ is an outer measure. Now set

$$\theta_r A = \sup_{\delta>0} \theta_{r\delta} A$$

for $A \subseteq X$; θ_r also is an outer measure on X, as in 264B; this is **r-dimensional Hausdorff outer measure** on X. Let μ_{Hr} be the measure defined by Carathéodory's method from θ_r; μ_{Hr} is **r-dimensional Hausdorff measure** on X.

Notation It may help if I list some notation already used elsewhere. Suppose that (X, ρ) is a metric space. I write

$$B(x, \delta) = \{y : \rho(y, x) \leq \delta\}, \quad U(x, \delta) = \{y : \rho(y, x) < \delta\}$$

for $x \in X$, $\delta \geq 0$; recall that $U(x, \delta)$ is open (2A3G). For $x \in X$ and A, $A' \subseteq X$ I write

$$\rho(x, A) = \inf_{y\in A} \rho(x, y), \quad \rho(A, A') = \inf_{y\in A, z\in A'} \rho(y, z);$$

for definiteness, take $\inf \emptyset$ to be ∞, as before.

471B Definition Let (X, ρ) be a metric space. An outer measure θ on X is a **metric outer measure** if $\theta(A_1 \cup A_2) = \theta A_1 + \theta A_2$ whenever A_1, $A_2 \subseteq X$ and $\rho(A_1, A_2) > 0$.

471C Proposition Let (X,ρ) be a metric space and θ a metric outer measure on X. Let μ be the measure on X defined from θ by Carathéodory's method. Then μ is a topological measure.

proof (Compare 264E, part (b) of the proof.) Let $G \subseteq X$ be open, and A any subset of X such that $\theta A < \infty$. Set

$$A_n = \{x : x \in A,\ \rho(x, A \setminus G) \geq 2^{-n}\},$$

$$B_0 = A_0, \quad B_n = A_n \setminus A_{n-1} \text{ for } n > 1.$$

Observe that $A_n \subseteq A_{n+1}$ for every n and $\bigcup_{n\in\mathbb{N}} A_n = \bigcup_{n\in\mathbb{N}} B_n = A \cap G$. The point is that if m, $n \in \mathbb{N}$ and $n \geq m+2$, and if $x \in B_m$ and $y \in B_n$, then there is a $z \in A \setminus G$ such that $\rho(y,z) < 2^{-n+1} \leq 2^{-m-1}$, while $\rho(x,z)$ must be at least 2^{-m}, so $\rho(x,y) \geq \rho(x,z) - \rho(y,z) \geq 2^{-m-1}$. Thus $\rho(B_m, B_n) > 0$ whenever $n \geq m+2$. It follows that for any $k \geq 0$

$$\textstyle\sum_{m=0}^{k} \theta B_{2m} = \theta(\bigcup_{m\leq k} B_{2m}) \leq \theta(A \cap G) < \infty,$$

$$\textstyle\sum_{m=0}^{k} \theta B_{2m+1} = \theta(\bigcup_{m\leq k} B_{2m+1}) \leq \theta(A \cap G) < \infty.$$

Consequently $\sum_{n=0}^{\infty} \theta B_n < \infty$.

But now, given $\epsilon > 0$, there is an m such that $\sum_{n=m}^{\infty} \theta B_m \leq \epsilon$, so that

$$\begin{aligned}\theta(A \cap G) + \theta(A \setminus G) &\leq \theta A_m + \sum_{n=m}^{\infty} \theta B_n + \theta(A \setminus G)\\ &\leq \epsilon + \theta A_m + \theta(A \setminus G) = \epsilon + \theta(A_m \cup (A \setminus G))\end{aligned}$$

(since $\rho(A_m, A \setminus G) \geq 2^{-m}$)

$$\leq \epsilon + \theta A.$$

As ϵ is arbitrary, $\theta(A \cap G) + \theta(A \setminus G) \leq \theta A$. As A is arbitrary, G is measured by μ; as G is arbitrary, μ is a topological measure.

471D Theorem Let (X,ρ) be a metric space and $r > 0$. Let μ_{Hr} be r-dimensional Hausdorff measure on X, and Σ its domain; write θ_r for r-dimensional Hausdorff outer measure on X, as defined in 471A.

(a) μ_{Hr} is a topological measure.

(b) For every $A \subseteq X$ there is a G_δ set $H \supseteq A$ such that $\mu_{Hr} H = \theta_r A$.

(c) θ_r is the outer measure defined from μ_{Hr} (that is, θ_r is a regular outer measure).

(d) Σ is closed under Souslin's operation.

(e) $\mu_{Hr} E = \sup\{\mu_{Hr} F : F \subseteq E \text{ is closed}\}$ whenever $E \in \Sigma$ and $\mu_{Hr} E < \infty$.

(f) If $A \subseteq X$ and $\theta_r A < \infty$ then A is separable and the set of isolated points of A is μ_{Hr}-negligible.

(g) μ_{Hr} is atomless.

(h) If μ_{Hr} is totally finite it is a quasi-Radon measure.

proof (a) The point is that θ_r, as defined in 471A, is a metric outer measure. **P** (Compare 264E, part (a) of the proof.) Let A_1, A_2 be subsets of X such that $\rho(A_1, A_2) > 0$. Of course $\theta(A_1 \cup A_2) \leq \theta_r A_1 + \theta_r A_2$, because θ_r is an outer measure. For the reverse inequality, we may suppose that $\theta_r(A_1 \cup A_2) < \infty$, so that $\theta_r A_1$ and $\theta_r A_2$ are both finite. Let $\epsilon > 0$ and let δ_1, $\delta_2 > 0$ be such that

$$\theta_r A_1 + \theta_r A_2 \leq \theta_{r\delta_1} A_1 + \theta_{r\delta_2} A_2 + \epsilon,$$

defining the $\theta_{r\delta_i}$ as in 471A. Set $\delta = \min(\delta_1, \delta_2, \frac{1}{2}\rho(A_1, A_2)) > 0$ and let $\langle D_n\rangle_{n\in\mathbb{N}}$ be a sequence of sets of diameter at most δ, covering $A_1 \cup A_2$, and such that $\sum_{n=0}^{\infty} (\operatorname{diam} D_n)^r \leq \theta_{r\delta}(A_1 \cup A_2) + \epsilon$. Set

$$K = \{n : D_n \cap A_1 \neq \emptyset\}, \quad L = \{n : D_n \cap A_2 \neq \emptyset\}.$$

Because $\rho(x,y) > \operatorname{diam} D_n$ whenever $x \in A_1$, $y \in A_2$ and $n \in \mathbb{N}$, $K \cap L = \emptyset$; and of course $A_1 \subseteq \bigcup_{n\in K} D_k$, $A_2 \subseteq \bigcup_{n\in L} D_n$. Consequently

$$\theta_r A_1 + \theta_r A_2 \leq \epsilon + \theta_{r\delta_1} A_1 + \theta_{r\delta_2} A_2 \leq \epsilon + \sum_{n\in K} (\operatorname{diam} D_n)^r + \sum_{n\in L} (\operatorname{diam} D_n)^r$$
$$\leq \epsilon + \sum_{n=0}^{\infty} (\operatorname{diam} D_n)^r \leq 2\epsilon + \theta_{r\delta}(A_1 \cup A_2) \leq 2\epsilon + \theta_r(A_1 \cup A_2).$$

As ϵ is arbitrary, $\theta_r(A_1 \cup A_2) \geq \theta_r A_1 + \theta_r A_2$. The reverse inequality is true just because θ_r is an outer measure, so $\theta_r(A_1 \cup A_2) = \theta_r A_1 + \theta_r A_2$. As A_1 and A_2 are arbitrary, θ_r is a metric outer measure. **Q**

Now 471C tells us that μ_{Hr} must be a topological measure.

(b) (Compare 264Fa.) If $\theta_r A = \infty$ this is trivial. Otherwise, for each $n \in \mathbb{N}$, let $\langle D_{ni}\rangle_{i\in\mathbb{N}}$ be a sequence of sets of diameter at most 2^{-n} such that $A \subseteq \bigcup_{i\in\mathbb{N}} D_i$ and $\sum_{i=0}^{\infty} (\operatorname{diam} D_{ni})^r \leq \theta_{r,2^{-n}}(A) + 2^{-n}$, defining $\theta_{r,2^{-n}}$ as in 471A. Let $\eta_{ni} \in]0, 2^{-n}]$ be such that $(2\eta_{ni} + \operatorname{diam} D_{ni})^r \leq 2^{-n-i} + (\operatorname{diam} D_{ni})^r$, and set $G_{ni} = \{x : \rho(x, D_{ni}) < \eta_{ni}\}$ for all n, $i \in \mathbb{N}$; then $G_{ni} = \bigcup_{x\in D_{ni}} U(x, \eta_{ni})$ is an open set including D_{ni} and $(\operatorname{diam} G_{ni})^r \leq 2^{-n-i} + (\operatorname{diam} D_{ni})^r$. Set

$$H = \bigcap_{n\in\mathbb{N}} \bigcup_{i\in\mathbb{N}} G_{ni},$$

so that H is a G_δ set including A.

For any $\delta > 0$, there is an $n \in \mathbb{N}$ such that $3 \cdot 2^{-n} \leq \delta$, so that $\operatorname{diam} G_{mi} \leq \operatorname{diam} D_{mi} + 2\eta_{mi} \leq \delta$ for every $i \in \mathbb{N}$ and $m \geq n$, and

$$\theta_{r\delta}(H) \leq \sum_{i=0}^{\infty} (\operatorname{diam} G_{mi})^r \leq \sum_{i=0}^{\infty} 2^{-m-i} + (\operatorname{diam} D_{mi})^r$$
$$\leq 2^{-m+1} + \theta_{r,2^{-m}}(A) + 2^{-m} \leq 2^{-m+2} + \theta_r(A)$$

for every $m \geq n$. Accordingly $\theta_{r\delta} H \leq \theta_r A$ for every $\delta > 0$, so $\theta_r H \leq \theta_r A$. Of course this means that $\theta_r H = \theta_r A$; and since, by (a), μ_{Hr} measures H, we have $\mu_{Hr} H = \theta_r A$, as required.

(c) (Compare 264Fb.) If $A \subseteq X$,

$$\theta_r A \geq \mu^*_{Hr} A$$

(by (b))

$$= \inf\{\theta_r E : A \subseteq E \in \Sigma\} \geq \theta_r A.$$

(d) Use 431C.

(e) By (b), there is a Borel set $H \supseteq E$ such that $\mu_{Hr} H = \mu_{Hr} E$, and now there is a Borel set $H' \supseteq H \setminus E$ such that $\mu_{Hr} H' = \mu_{Hr}(H \setminus E) = 0$, so that $G = H \setminus H'$ is a Borel set included in E and $\mu_{Hr} G = \mu_{Hr} E$. Now G is a Baire set (4A3Kb), so is Souslin-F (421L), and $\mu_{Hr} G = \sup_{F\subseteq G \text{ is closed}} \mu_{Hr} F$, by 431E.

(f) For every $n \in \mathbb{N}$, there must be a sequence $\langle D_{ni}\rangle_{i\in\mathbb{N}}$ of sets of diameter at most 2^{-n} covering A; now if $D \subseteq A$ is a countable set which meets D_{ni} whenever i, $n \in \mathbb{N}$ and $A \cap D_{ni} \neq \emptyset$, D will be dense in A. Now if A_0 is the set of isolated points in A, it is still separable (4A2P(a-iv)); but as the only dense subset of A_0 is itself, it is countable. Since $\theta_{r\delta}\{x\} = (\operatorname{diam}\{x\})^r = 0$ for every $\delta > 0$, $\mu_{Hr}\{x\} = 0$ for every $x \in X$, and A_0 is negligible.

(g) In fact, if $A \subseteq X$ and $\theta_r A > 0$, there are disjoint A_0, $A_1 \subseteq A$ such that $\theta_r A_i > 0$ for both i. **P** (i) Suppose first that A is not separable. For each $n \in \mathbb{N}$, let $D_n \subseteq A$ be a maximal set such that $\rho(x, y) \geq 2^{-n}$ for all distinct x, $y \in D_n$; then $\bigcup_{n\in\mathbb{N}} D_n$ is dense in A, so there is some $n \in \mathbb{N}$ such that D_n is uncountable; if we take A_1, A_2 to be disjoint uncountable subsets of D_n, then $\theta_r A_1 = \theta_r A_2 = \infty$. (ii) If A is separable, then set $\mathcal{G} = \{G : G \subseteq X \text{ is open}, \theta_r(A \cap G) = 0\}$. Because A is hereditarily Lindelöf (4A2P(a-iii)), there is a countable subset $\mathcal{G}_0$ of $\mathcal{G}$ such that $A \cap \bigcup \mathcal{G} = A \cap \bigcup \mathcal{G}_0$ (4A2H(c-i)), so $A \cap \bigcup \mathcal{G}$ is negligible and $A \setminus \bigcup \mathcal{G}$ has at least two points x_0, x_1. If we set $A_i = U(x_i, \frac{1}{2}\rho(x_i, x_{1-i}))$ for each i, these are disjoint subsets of A of non-zero outer measure. **Q**

(h) If μ_{Hr} is totally finite, then it is inner regular with respect to the closed sets, by (e). Also, because X must be separable, by (f), therefore hereditarily Lindelöf, μ_{Hr} must be τ-additive (414O). Finally, μ_{Hr} is complete just because it is defined by Carathéodory's method. So μ_{Hr} is a quasi-Radon measure.

471E Corollary If (X,ρ) is a metric space, $r>0$ and $Y\subseteq X$ then r-dimensional Hausdorff measure $\mu_{Hr}^{(Y)}$ on Y extends the subspace measure $(\mu_{Hr}^{(X)})_Y$ on Y induced by r-dimensional Hausdorff measure $\mu_{Hr}^{(X)}$ on X; and if either Y is measured by $\mu_{Hr}^{(X)}$ or Y has finite r-dimensional Hausdorff outer measure in X, then $\mu_{Hr}^{(Y)}=(\mu_{Hr}^{(X)})_Y$.

proof Write $\theta_r^{(X)}$ and $\theta_r^{(Y)}$ for the two r-dimensional Hausdorff outer measures.

If $A\subseteq Y$ and $\langle D_n\rangle_{n\in\mathbb{N}}$ is any sequence of subsets of X covering A, then $\langle D_n\cap Y\rangle_{n\in\mathbb{N}}$ is a sequence of subsets of Y covering A, and $\sum_{n=0}^\infty(\operatorname{diam}(D_n\cap Y))^r\le\sum_{n=0}^\infty(\operatorname{diam}D_n)^r$; moreover, when calculating $\operatorname{diam}(D_n\cap Y)$, it doesn't matter whether we use the metric ρ on X or the subspace metric $\rho\restriction Y\times Y$ on Y. What this means is that, for any $\delta>0$, $\theta_{r\delta}A$ is the same whether calculated in Y or in X, so that $\theta_r^{(Y)}A=\sup_{\delta>0}\theta_{r\delta}A=\theta_r^{(X)}A$.

Thus $\theta_r^{(Y)}=\theta_r^{(X)}\restriction\mathcal{P}Y$. Also, by 471Db, $\theta_r^{(X)}$ is a regular outer measure. So 214Hb gives the results.

471F Corollary Let (X,ρ) be an analytic metric space (that is, a metric space in which the topology is analytic in the sense of §423), and write μ_{Hr} for r-dimensional Hausdorff measure on X. Suppose that ν is a locally finite indefinite-integral measure over μ_{Hr}. Then ν is a Radon measure.

proof Since $\operatorname{dom}\nu\supseteq\operatorname{dom}\mu$, ν is a topological measure. Because X is separable, therefore hereditarily Lindelöf, ν is σ-finite and τ-additive, therefore locally determined and effectively locally finite. Next, it is inner regular with respect to the closed sets. **P** Let f be a Radon-Nikodým derivative of ν. If $\nu E>0$, there is an $E'\subseteq E$ such that

$$0<\nu E'=\int f\times\chi E'\,d\mu_{Hr}<\infty.$$

There is a μ_{Hr}-simple function g such that $g\le f\times\chi E'$ μ_{Hr}-a.e. and $\int g\,d\mu_{Hr}>0$; setting $H=E'\cap\{x:g(x)>0\}$, $\nu_{Hr}H<\infty$. Now there is a closed set $F\subseteq H$ such that $\mu_{Hr}F>0$, by 471De, and in this case $\nu F\ge\int_F g\,d\mu_{Hr}>0$. By 412B, this is enough to show that ν is inner regular with respect to the closed sets. **Q**

Since ν is complete (234A), it is a quasi-Radon measure, therefore a Radon measure (434Jf, 434Jb).

471G Increasing Sets Lemma(Davies 70) Let (X,ρ) be a metric space and $r>0$.

(a) Suppose that $\delta>0$ and that $\langle A_n\rangle_{n\in\mathbb{N}}$ is a non-decreasing sequence of subsets of X with union A. Then $\theta_{r,6\delta}(A)\le(5^r+2)\sup_{n\in\mathbb{N}}\theta_{r\delta}(A_n)$.

(b) Suppose that $\delta>0$ and that $\langle A_n\rangle_{n\in\mathbb{N}}$ is a non-decreasing sequence of subsets of X with union A. Then $\theta_{r\delta}A\le\sup_{n\in\mathbb{N}}\theta_{r\delta}A_n$.

proof (a) If $\sup_{n\in\mathbb{N}}\theta_{r\delta}(A_n)=\infty$ this is trivial; suppose otherwise.

(i) Take any $\gamma>\gamma'>\sup_{n\in\mathbb{N}}\theta_{r\delta}(A_n)$. For each $i\in\mathbb{N}$, let $\zeta_i\in\left]0,\frac{1}{6}\delta\right]$ be such that $(\alpha+2\zeta_i)^r\le\alpha^r+2^{-i-1}(\gamma-\gamma')$ whenever $0\le\alpha\le\delta$. For each $n\in\mathbb{N}$, there is a sequence $\langle C_{ni}\rangle_{i\in\mathbb{N}}$ of sets covering A_n such that $\operatorname{diam}C_{ni}\le\delta$ for every i and $\sum_{i=0}^\infty(\operatorname{diam}C_{ni})^r\le\gamma'$. Since $\sum_{i=0}^\infty(\operatorname{diam}C_{ni})^r$ is finite, $\lim_{i\to\infty}\operatorname{diam}C_{ni}=0$; rearranging the sequence, we may suppose that $\operatorname{diam}C_{ni}+\zeta_i\ge\operatorname{diam}C_{n,i+1}$ for every i.

In this case, $\lim_{i\to\infty}\sup_{n\in\mathbb{N}}\operatorname{diam}C_{ni}=0$. **P** Given $\epsilon>0$, take k such that $\sum_{j=0}^k\max(0,\epsilon-\zeta_j)^r>\gamma$. For any $i\ge k$ and $n\in\mathbb{N}$, $\operatorname{diam}C_{nj}\ge\max(0,\operatorname{diam}C_{ni}-\zeta_j)$ for every $j\le k$, and $\sum_{j=0}^k(\operatorname{diam}C_{nj})^r\le\gamma$, so $\operatorname{diam}C_{ni}\le\epsilon$. **Q**

(ii) By Ramsey's theorem (4A1G, with $n=2$), there is an infinite set $I\subseteq\mathbb{N}$ such that

for all i, $j\in\mathbb{N}$ there is an $s\in\mathbb{N}$ such that either $C_{mi}\cap C_{nj}=\emptyset$ whenever m, $n\in I$ and $s\le m<n$ or $C_{mi}\cap C_{nj}\ne\emptyset$ whenever m, $n\in I$ and $s\le m<n$,

for each $i\in\mathbb{N}$, $\alpha_i=\lim_{n\in I,n\to\infty}\operatorname{diam}C_{ni}$ is defined in $\mathbb{R}$.

(Apply 4A1Fb with the families

$$\begin{aligned}\mathcal{J}_{ij}=\{J:J\in[\mathbb{N}]^\omega,&\text{ either }C_{mi}\cap C_{nj}=\emptyset\text{ whenever }m,n\in J\text{ and }m<n\\&\text{or }C_{mi}\cap C_{nj}\ne\emptyset\text{ whenever }m,n\in J\text{ and }m<n\}\\\mathcal{J}'_{iq}=\{J:J\in[\mathbb{N}]^\omega,&\text{ either }\operatorname{diam}C_{ni}\le q\text{ for every }n\in J\\&\text{or }\operatorname{diam}C_{ni}\ge q\text{ for every }n\in J\}\end{aligned}$$

for i, $j \in \mathbb{N}$ and $q \in \mathbb{Q}$.)

Of course $\alpha_j - \zeta_i \leq \alpha_i \leq \delta$ whenever $i \leq j$, because $\operatorname{diam} C_{nj} - \zeta_i \leq \operatorname{diam} C_{ni} \leq \delta$ for every n. Set $D_{ni} = \{x : \rho(x, C_{ni}) \leq 2\alpha_i + 3\zeta_i\}$ for all n, $i \in \mathbb{N}$, and $D_i = \bigcup_{s\in\mathbb{N}} \bigcap_{n\in I\setminus s} D_{ni}$ for $i \in \mathbb{N}$. (I am identifying each $s \in \mathbb{N}$ with the set of its predecessors.)

(iii) Set

$$L = \{(i,j) : i, j \in \mathbb{N}, \forall\, s \in \mathbb{N}\ \exists\, m, n \in I, s \leq m < n \text{ and } C_{mi} \cap C_{nj} \neq \emptyset\}.$$

If $(i,j) \in L$ then there is an $s \in \mathbb{N}$ such that $C_{mi} \subseteq D_{\min(i,j)}$ whenever $m \in I$ and $m \geq s$. **P** By the choice of I, we know that there is an $s_0 \in \mathbb{N}$ such that $C_{mi} \cap C_{nj} \neq \emptyset$ whenever m, $n \in I$ and $s_0 \leq m < n$. Let $s_1 \geq s_0$ be such that

$$\operatorname{diam} C_{mi} \leq \alpha_i + \min(\zeta_i, \zeta_j), \quad \operatorname{diam} C_{mj} \leq \alpha_j + \min(\zeta_i, \zeta_j)$$

whenever $m \in I$ and $m \geq s_1$. Take $m_0 \in I$ such that $m_0 \geq s_1$, and set $s = m_0 + 1$. Let $m \in I$ be such that $m \geq s$.

($\boldsymbol{\alpha}$) Suppose that $i \leq j$ and $x \in C_{mi}$. Take any $n \in I$ such that $m \leq n$. Then there is an $n' \in I$ such that $n < n'$. We know that $C_{mi} \cap C_{n'j}$ and $C_{ni} \cap C_{n'j}$ are both non-empty. So

$$\rho(x, C_{ni}) \leq \operatorname{diam} C_{mi} + \operatorname{diam} C_{n'j} \leq \alpha_i + \zeta_i + \alpha_j + \zeta_i \leq 2\alpha_i + 3\zeta_i$$

and $x \in D_{ni}$. This is true for all $n \in I$ such that $n \geq m$, so $x \in D_i$. As x is arbitrary, $C_{mi} \subseteq D_i$.

($\boldsymbol{\beta}$) Suppose that $j \leq i$ and $x \in C_{mi}$. Take any $n \in I$ such that $n > m$. Then $C_{mi} \cap C_{nj}$ is not empty, so

$$\rho(x, C_{nj}) \leq \operatorname{diam} C_{mi} \leq \alpha_i + \zeta_j \leq \alpha_j + 2\zeta_j$$

and $x \in D_{nj}$. As x and n are arbitrary, $C_{mi} \subseteq D_j$.

Thus $C_{mi} \subseteq D_{\min(i,j)}$ in both cases. **Q**

(iv) Set

$$D = \textstyle\bigcup_{i\in\mathbb{N}} D_i, \quad J = \{i : i \in \mathbb{N}, \exists\, s \in \mathbb{N}, C_{ni} \subseteq D \text{ whenever } n \in I \text{ and } n \geq s\}.$$

If $i \in \mathbb{N} \setminus J$ and $j \in \mathbb{N}$, then (iii) tells us that $(i,j) \notin L$, so there is some $s \in \mathbb{N}$ such that $C_{mi} \cap C_{nj} = \emptyset$ whenever m, $n \in I$ and $s \leq m < n$.

(v) For $l \in \mathbb{N}$, $\mu^*_{Hr}(A_l \setminus D) \leq 2\gamma$. **P** Let $\epsilon > 0$. Then there is a $k \in \mathbb{N}$ such that $\operatorname{diam} C_{ni} \leq \epsilon$ whenever $n \in \mathbb{N}$ and $i > k$. Next, there is an $s \in \mathbb{N}$ such that

$$C_{ni} \subseteq D \text{ whenever } i \leq k,\ i \in J,\ n \in I \text{ and } s \leq n,$$

$$C_{mi} \cap C_{nj} = \emptyset \text{ whenever } i, j \leq k,\ i \notin J,\ m, n \in I \text{ and } s \leq m < n.$$

Take m, $n \in I$ such that $\max(l, s) \leq m < n$. Then

$$\begin{aligned}
A_l \setminus D &= \bigcup_{i\in\mathbb{N}} A_l \cap C_{mi} \setminus D \\
&\subseteq \bigcup_{i\leq k} (A_n \cap C_{mi} \setminus D) \cup \bigcup_{i>k} C_{mi} \\
&\subseteq \bigcup_{i\leq k, i\notin J} (A_n \cap C_{mi}) \cup \bigcup_{i>k} C_{mi} \\
&\subseteq \bigcup_{i\leq k, i\notin J, j\leq k} (C_{mi} \cap C_{nj}) \cup \bigcup_{j>k} C_{nj} \cup \bigcup_{i>k} C_{mi} \\
&= \bigcup_{j>k} C_{nj} \cup \bigcup_{i>k} C_{mi}.
\end{aligned}$$

Since $\operatorname{diam} C_{nj} \leq \epsilon$ and $\operatorname{diam} C_{mi} \leq \epsilon$ for all i, $j > k$,

$$\theta_{r\epsilon}(A_l \setminus D) \leq \textstyle\sum_{i=k+1}^{\infty} (\operatorname{diam} C_{ni})^r + \sum_{i=k+1}^{\infty} (\operatorname{diam} C_{mi})^r \leq 2\gamma.$$

This is true for every $\epsilon > 0$, so $\mu^*_{Hr}(A_l \setminus D) \leq 2\gamma$, as claimed. **Q**

(vi) This is true for each $l \in \mathbb{N}$. But this means that $\mu^*_{Hr}(A \setminus D) \leq 2\gamma$ (132Ae). Now $\theta_{r,6\delta}D \leq 5^r\gamma$. **P** For each $i \in \mathbb{N}$,

$$\begin{aligned}\operatorname{diam} D_i &\leq \lim_{n\in I, n\to\infty} \operatorname{diam} D_{ni}\\ &\leq \lim_{n\in I, n\to\infty} \operatorname{diam} C_{ni} + 4\alpha_i + 6\zeta_i = 5\alpha_i + 6\zeta_i \leq 6\delta.\end{aligned}$$

Next, for any $k \in \mathbb{N}$,

$$\textstyle\sum_{i=0}^k \alpha_i^r = \lim_{n\in I, n\to\infty} \sum_{i=0}^k (\operatorname{diam} C_{ni})^r \leq \gamma',$$

so

$$\sum_{i=0}^k (\operatorname{diam} D_i)^r \leq 5^r \sum_{i=0}^k (\alpha_i + 2\zeta_i)^r \leq 5^r (\sum_{i=0}^k \alpha_i^r + 2^{-i-1}(\gamma - \gamma'))$$

(by the choice of the ζ_i)

$$\leq 5^r\gamma.$$

Letting $k \to \infty$,

$$\theta_{r,6\delta}D \leq \textstyle\sum_{i=0}^\infty (\operatorname{diam} D_i)^r \leq 5^r\gamma.$$ **Q**

Putting these together,

$$\theta_{r,6\delta}A \leq \theta_{r,6\delta}D + \theta_{r,6\delta}(A \setminus D) \leq \theta_{r,6\delta}D + \mu^*_{Hr}(A \setminus D) \leq (5^r + 2)\gamma.$$

As γ is arbitrary, we have the preliminary result (a).

(b) Now let us turn to the sharp form (b). Once again, we may suppose that $\sup_{n\in\mathbb{N}} \theta_{r\delta}A_n$ is finite.

(i) Take γ, γ' such that $\sup_{n\in\mathbb{N}} \theta_{r\delta}A_n < \gamma' < \gamma$. As in (a)(i) above, we can find a family $\langle C_{ni}\rangle_{n,i\in\mathbb{N}}$ such that

$$A_n \subseteq \textstyle\bigcup_{i\in\mathbb{N}} C_{ni},$$

$$\operatorname{diam} C_{ni} \leq \delta \text{ for every } i \in \mathbb{N},$$

$$\textstyle\sum_{i=0}^\infty (\operatorname{diam} C_{ni})^r \leq \gamma'$$

for each n, and

$$\lim_{i\to\infty} \sup_{n\in\mathbb{N}} \operatorname{diam} C_{ni} = 0.$$

Replacing each C_{ni} by its closure if necessary, we may suppose that every C_{ni} is a Borel set.

Let $Q \subseteq X$ be a countable set which meets C_{ni} whenever n, $i \in \mathbb{N}$ and C_{ni} is not empty. This time, let $I \subseteq \mathbb{N}$ be an infinite set such that

$$\alpha_i = \lim_{n\in I, n\to\infty} \operatorname{diam} C_{ni} \text{ is defined in } [0, \delta] \text{ for every } i \in \mathbb{N},$$

$$\lim_{n\in I, n\to\infty} \rho(z, C_{ni}) \text{ is defined in } [0, \infty] \text{ for every } i \in \mathbb{N} \text{ and every } z \in Q.$$

(Take $\rho(z, \emptyset) = \infty$ if any of the C_{ni} are empty.) It will be helpful to note straight away that the limit $\lim_{n\in I, n\to\infty} \rho(x, C_{ni})$ is defined in $[0, \infty]$ for every $i \in \mathbb{N}$ and $x \in \overline{Q}$. **P** If $\lim_{n\in I, n\to\infty} \rho(y, C_{ni}) = \infty$ for any $z \in Q$, then $\lim_{n\in I, n\to\infty} \rho(x, C_{ni}) = \infty$, and we can stop. Otherwise, for any $\epsilon > 0$, there are a $z \in Q$ such that $\rho(x, z) \leq \epsilon$ and an $s \in \mathbb{N}$ such that C_{mi} is not empty and $|\rho(z, C_{mi}) - \rho(z, C_{ni})| \leq \epsilon$ whenever m, $n \in I \setminus s$; in which case $|\rho(x, C_{mi}) - \rho(x, C_{ni})| \leq 3\epsilon$ whenever m, $n \in I \setminus s$. As ϵ is arbitrary, $\lim_{n\in I, n\to\infty} \rho(x, C_{ni})$ is defined in $\mathbb{R}$. **Q**

Let $\mathcal{F}$ be a non-principal ultrafilter on $\mathbb{N}$ containing I, and for $i \in \mathbb{N}$ set

$$D_i = \{x : \lim_{n\to\mathcal{F}} \rho(x, C_{ni}) = 0\}.$$

Set $D = \bigcup_{i\in\mathbb{N}} \overline{D}_i$. (Actually it is easy to check that every D_i is closed.)

(ii) Set

$$A^* = \bigcup_{m\in\mathbb{N}} \bigcap_{n\in I\setminus m} \bigcup_{i\in\mathbb{N}} C_{ni} \setminus D;$$

note that A^* is a Borel set. For k, $m \in \mathbb{N}$, set

$$A^*_{km} = \bigcap_{n\in I\setminus m} \bigcup_{i\geq k} C_{ni}.$$

For fixed k, $\langle A^*_{km}\rangle_{m\in\mathbb{N}}$ is a non-decreasing sequence of sets. Also its union includes A^*. **P** Take $x \in A^*$.

(α)? If $x \notin \overline{Q}$, let $\epsilon > 0$ be such that $Q \cap B(x,\epsilon) = \emptyset$. Let $k \in \mathbb{N}$ be such that $\operatorname{diam} C_{ni} \leq \epsilon$ whenever $n \in \mathbb{N}$ and $i \geq k$; then $x \notin C_{ni}$ whenever $n \in \mathbb{N}$ and $i \geq k$. Let $m \in \mathbb{N}$ be such that $x \in \bigcup_{i\in\mathbb{N}} C_{ni}$ whenever $n \in I$ and $n \geq m$. Then $x \in \bigcup_{i<k} C_{ni}$ whenever $n \in I$ and $n \geq m$. But this means that there must be some $i < k$ such that $\{n : x \in C_{ni}\} \in \mathcal{F}$ and $x \in D_i \subseteq D$; which is impossible. **X**

(β) Thus $x \in \overline{Q}$, so $\lim_{n\in I, n\to\infty} \rho(x, C_{ni})$ is defined for each i (see (i) above), and must be greater than 0, since $x \notin D_i$. In particular, there is an $s \in \mathbb{N}$ such that $x \notin C_{ni}$ whenever $i < k$ and $n \in I \setminus s$; there is also an $m \in \mathbb{N}$ such that $x \in \bigcap_{n\in I\setminus m} \bigcup_{i\in\mathbb{N}} C_{ni}$; so that $x \in A^*_{k,\max(s,m)}$. As x is arbitrary, $A^* \subseteq \bigcup_{m\in\mathbb{N}} A^*_{km}$. **Q**

(iii) $\mu_{Hr}A^*$ is finite. **P** Take any $\epsilon > 0$. Let $k \in \mathbb{N}$ be such that $\operatorname{diam} C_{ni} \leq \epsilon$ whenever $i \geq k$ and $n \in \mathbb{N}$. For any $m \in I$, $\theta_{r\epsilon}A^*_{km} \leq \sum_{i=k}^{\infty} (\operatorname{diam} C_{mi})^r \leq \gamma$. By (a),

$$\begin{aligned}\theta_{r,6\epsilon}A^* &\leq (5^r+2)\sup_{m\in\mathbb{N}} \theta_{r\epsilon}A^*_{km}\\ &= (5^r+2)\sup_{m\in I} \theta_{r\epsilon}A^*_{km} \leq (5^r+2)\gamma.\end{aligned}$$

As ϵ is arbitrary, $\mu_{Hr}A^* \leq (5^r+2)\gamma < \infty$. **Q**

(iv) Actually, $\mu_{Hr}A^* \leq \gamma' - \sum_{i=0}^{\infty} \alpha_i^r$. **P?** Suppose, if possible, otherwise. Take β such that $\gamma' - \sum_{i=0}^{\infty} \alpha_i^r < \beta < \mu_{Hr}A^*$. For $x \in A^*$ and $k \in \mathbb{N}$, set $f_k(x) = \min\{n : n \in I,\ x \in A^*_{kn}\}$; then $\langle f_k\rangle_{k\in\mathbb{N}}$ is a non-decreasing sequence of Borel measurable functions from A^* to $\mathbb{N}$. Choose $\langle s_k\rangle_{k\in\mathbb{N}}$ inductively so that

$$\mu_{Hr}\{x : x \in A^*,\ f_j(x) \leq s_j \text{ for every } j \leq k\} \geq \beta$$

for every $k \in \mathbb{N}$. Set $\tilde{A} = \{x : x \in A^*,\ f_j(x) \leq s_j \text{ for every } j \in \mathbb{N}\}$; because $\mu_{Hr}A^*$ is finite, $\mu_{Hr}\tilde{A} \geq \beta$. Take $\epsilon > 0$ such that $\theta_{r\epsilon}\tilde{A} > \gamma' - \sum_{i=0}^{\infty} \alpha_i^r$. Let $k \in \mathbb{N}$ be such that $\theta_{r\epsilon}\tilde{A} + \sum_{i=0}^{k-1} \alpha_i^r > \gamma'$ and $\operatorname{diam} C_{ni} \leq \epsilon$ whenever $n \in \mathbb{N}$ and $i \geq k$. Take $n \in I$ such that $n \geq s_j$ for every $j < k$ and $\theta_{r\epsilon}\tilde{A} + \sum_{i=0}^{k-1} (\operatorname{diam} C_{ni})^r > \gamma'$. If $x \in \tilde{A}$, then $x \in A^*_{kn} \subseteq \bigcup_{i\geq k} C_{ni}$, so $\theta_{r\epsilon}\tilde{A} \leq \sum_{i=k}^{\infty} (\operatorname{diam} C_{ni})^r$; but this means that $\sum_{i=0}^{\infty} (\operatorname{diam} C_{ni})^r > \gamma'$, contrary to the choice of the C_{ni}. **XQ**

(v) Now observe that

$$A \subseteq \bigcup_{m\in\mathbb{N}} \bigcap_{n\geq m} \bigcup_{i\in\mathbb{N}} C_{ni} \subseteq A^* \cup D.$$

Moreover, for any $i \in \mathbb{N}$, $\operatorname{diam} \overline{D}_i \leq \alpha_i \leq \delta$. **P** If x, $y \in D_i$ then for every $\epsilon > 0$

$$\rho(x, C_{ni}) \leq \epsilon, \quad \rho(y, C_{ni}) \leq \epsilon, \quad \operatorname{diam} C_{ni} \leq \alpha_i + \epsilon$$

for all but finitely many $n \in I$. So $\rho(x,y) \leq \alpha_i + 3\epsilon$. As x, y and ϵ are arbitrary, $\operatorname{diam} \overline{D}_i = \operatorname{diam} D_i \leq \alpha_i$. Of course $\alpha_i \leq \delta$ because $\operatorname{diam} C_{ni} \leq \delta$ for every n. **Q**

Now

$$\theta_{r\delta}D \leq \sum_{i=0}^{\infty} (\operatorname{diam} \overline{D}_i)^r \leq \sum_{i=0}^{\infty} \alpha_i^r.$$

Putting this together with (iv),

$$\theta_{r\delta}A \leq \theta_{r\delta}D + \theta_{r\delta}A^* \leq \theta_{r\delta}D + \mu_{Hr}A^* \leq \gamma.$$

As γ and γ' are arbitrary,

$$\theta_{r\delta}A \leq \sup_{n\in\mathbb{N}} \theta_{r\delta}A_n,$$

as required.

471H Corollary Let (X,ρ) be a metric space, and $r>0$. For $A\subseteq X$, set

$$\theta_{r\infty}A=\inf\{\textstyle\sum_{n=0}^{\infty}(\operatorname{diam}D_n)^r : \langle D_n\rangle_{n\in\mathbb{N}} \text{ is a sequence of subsets of } X \text{ covering } A\}.$$

Then $\theta_{r\infty}$ is a capacity on X.

proof (a) Of course $0\le\theta_{r\infty}A\le\theta_{r\infty}B$ whenever $A\subseteq B\subseteq X$.

(b) Suppose that $\langle A_n\rangle_{n\in\mathbb{N}}$ is a non-decreasing sequence of subsets of A with union A. By (a), $\gamma=\lim_{n\to\infty}\theta_{r\infty}A_n$ is defined and less than or equal to $\theta_{r\infty}A$. If $\gamma=\infty$, of course it is equal to $\theta_{r\infty}A$. Otherwise, take $\delta=(\gamma+1)^{1/r}$. For n, $k\in\mathbb{N}$ there is a sequence $\langle D_{nki}\rangle_{i\in\mathbb{N}}$ of sets, covering A_n, such that $\sum_{i=0}^{\infty}(\operatorname{diam}D_{nki})^r\le\gamma+2^{-k}$. But in this case $\operatorname{diam}D_{nki}\le\delta$ for all n, k and i, so the D_{nki} witness that $\theta_{r\delta}A_n\le\gamma$. By 471Gb, $\gamma\ge\theta_{r\delta}A\ge\theta_{r\infty}A$ and again we have $\gamma=\theta_{r\infty}A$.

(c) Let $K\subseteq X$ be any set, and suppose that $\gamma>\theta_{r\infty}K$. Let $\langle D_n\rangle_{n\in\mathbb{N}}$ be a sequence of sets, covering K, such that $\sum_{n=0}^{\infty}(\operatorname{diam}D_n)^r<\gamma$. Let $\langle\epsilon_n\rangle_{n\in\mathbb{N}}$ be a sequence of strictly positive real numbers such that $\sum_{n=0}^{\infty}(\operatorname{diam}D_n+2\epsilon_n)^r\le\gamma$. Set $G_n=\{x:\rho(x,D_n)<\epsilon_n\}$ for each n; then G_n is open and $\operatorname{diam}G_n\le\operatorname{diam}D_n+2\epsilon_n$. So $G=\bigcup_{n\in\mathbb{N}}G_n$ is an open set including K, and $\langle G_n\rangle_{n\in\mathbb{N}}$ witnesses that $\theta_{r\infty}G\le\gamma$. As K and γ are arbitrary, condition (iii) of 432J is satisfied and $\theta_{r\infty}$ is a capacity.

Remark $\theta_{r\infty}$ is **r-dimensional Hausdorff capacity** on X.

471I Theorem Let (X,ρ) be a metric space, and $r>0$. Write μ_{Hr} for r-dimensional Hausdorff measure on X. If $A\subseteq X$ is analytic, then $\mu_{Hr}A$ is defined and equal to $\sup\{\mu_{Hr}K:K\subseteq A \text{ is compact}\}$.

proof (a) Before embarking on the main line of the proof, it will be convenient to set out a preliminary result. For $\delta>0$, $n\in\mathbb{N}$, $B\subseteq X$ set

$$\theta_{r\delta}^{(n)}(B)=\inf\{\textstyle\sum_{i=0}^{n}(\operatorname{diam}D_i)^r : B\subseteq\bigcup_{i\le n}D_i,\ \operatorname{diam}D_i\le\delta \text{ for every } i\le n\},$$

taking $\inf\emptyset=\infty$ as usual. Then $\theta_{r\delta}(B)\le\theta_{r\delta}^{(n)}(B)$ for every n. Now the point is that $\theta_{r\delta}^{(n)}(B)=\sup\{\theta_{r\delta}^{(n)}(I):I\subseteq B \text{ is finite}\}$. **P** Set $\gamma=\sup_{I\in[B]^{<\omega}}\theta_{r\delta}^{(n)}(I)$. Of course $\gamma\le\theta_{r\delta}^{(n)}(B)$. If $\gamma=\infty$ there is nothing more to say. Otherwise, take any $\gamma'>\gamma$. For each $I\in[B]^{<\omega}$, we have a function $f_I:I\to\{0,\dots,n\}$ such that $\sum_{i\in J}\rho(x_i,y_i)^r\le\gamma'$ whenever $J\subseteq\{0,\dots,n\}$ and x_i, $y_i\in I$ and $f_I(x_i)=f_I(y_i)=i$ for every $i\in J$, while $\rho(x,y)\le\delta$ whenever x, $y\in I$ and $f_I(x)=f_I(y)$. Let $\mathcal{F}$ be an ultrafilter on $[B]^{<\omega}$ such that $\{I:x\in I\in[B]^{<\omega}\}\in\mathcal{F}$ for every $x\in B$ (4A1Ia). Then for every $x\in B$ there is an $f(x)\in\{0,\dots,n\}$ such that $\{I:x\in I\in[B]^{<\omega},\ f_I(x)=f(x)\}\in\mathcal{F}$. Set $D_i=f^{-1}[\{i\}]$ for $i\le n$. If x, $y\in B$ and $f(x)=f(y)$, there is an $I\in[B]^{<\omega}$ containing both x and y such that $f_I(x)=f(x)=f(y)=f_I(y)$, so that $\rho(x,y)\le\delta$; thus $\operatorname{diam}D_i\le\delta$ for each i. If $J\subseteq\{0,\dots,n\}$ and for each $i\in J$ we take x_i, $y_i\in D_i$, then there is an $I\in[B]^{<\omega}$ such that $f_I(x_i)=f_I(y_i)=i$ for every $i\in J$, so $\sum_{i\in J}\rho(x_i,y_i)^r\le\gamma'$. This means that $\sum_{i\le n}(\operatorname{diam}D_i)^r\le\gamma'$, so that $\theta_{r\delta}^{(n)}(B)\le\gamma'$. As γ' is arbitrary, $\theta_{r\delta}^{(n)}(B)\le\gamma$, as claimed. **Q**

(b) Now let us turn to the set A. Because A is Souslin-F (422Ha), μ_{Hr} measures A (471Da, 471Dd). Set $\gamma=\sup\{\mu_{Hr}(K):K\subseteq A \text{ is compact}\}$.

? Suppose, if possible, that $\mu_{Hr}(A)>\gamma$. Take $\gamma'\in\,]\gamma,\mu_{Hr}(A)[$. Let $\delta>0$ be such that $\gamma'<\theta_{r\delta}(A)$. Let $f:\mathbb{N}^{\mathbb{N}}\to A$ be a continuous surjection. For $\sigma\in S^*=\bigcup_{n\in\mathbb{N}}\mathbb{N}^n$, set

$$F_\sigma=\{\phi:\phi\in\mathbb{N}^{\mathbb{N}},\ \phi(i)\le\sigma(i) \text{ for every } i<\#(\sigma)\},$$

so that $f[F_\emptyset]=A$. Now choose $\psi\in\mathbb{N}^{\mathbb{N}}$ and a sequence $\langle I_n\rangle_{n\in\mathbb{N}}$ of finite subsets of $\mathbb{N}^{\mathbb{N}}$ inductively, as follows. Given that $I_j\subseteq F_{\psi\restriction n}$ for every $j<n$ and that $\theta_{r\delta}(f[F_{\psi\restriction n}])>\gamma'$, then $\theta_{r\delta}^{(n)}(f[F_{\psi\restriction n}])>\gamma'$, so by (a) above there is a finite subset I_n of $F_{\psi\restriction n}$ such that $\theta_{r\delta}^{(n)}(f[I_n])\ge\gamma'$. Next,

$$\lim_{i\to\infty}\theta_{r\delta}f[F_{(\psi\restriction n)^\frown i}]=\theta_{r\delta}\bigcup_{i\in\mathbb{N}}f[F_{(\psi\restriction n)^\frown i}]$$

(by 471G)

$$=\theta_{r\delta}f[F_{\psi\restriction n}]>\gamma',$$

so we can take $\psi(n)$ such that $\bigcup_{j\le n} I_j \subseteq F_{\psi\restriction n+1}$ and $\theta_{r\delta} f[F_{\psi\restriction n+1}] > \gamma'$, and continue.

At the end of the induction, set $K = \{\phi : \phi \le \psi\}$. Then $f[K]$ is a compact subset of A, and $I_n \subseteq K$ for every $n \in \mathbb{N}$, so

$$\theta^{(n)}_{r\delta}(f[K]) \ge \theta^{(n)}_{r\delta}(f[I_n]) \ge \gamma'$$

for every $n \in \mathbb{N}$. On the other hand, $\mu_{Hr}(f[K]) \le \gamma$, so there is a sequence $\langle D_i\rangle_{i\in\mathbb{N}}$ of sets, covering $f[K]$, all of diameter less than δ, such that $\sum_{i=0}^{\infty}(\operatorname{diam} D_i)^r < \gamma'$. Enlarging the D_i slightly if need be, we may suppose that they are all open. But in this case there is some finite n such that $K \subseteq \bigcup_{i\le n} D_i$, and $\theta^{(n)}_{r\delta}(K) \le \sum_{i=0}^{n}(\operatorname{diam} D_i)^r < \gamma'$; which is impossible. **X**

This contradiction shows that $\mu_{Hr}(A) = \gamma$, as required.

471J Proposition Let (X,ρ) and (Y,σ) be metric spaces, and $f : X \to Y$ a function which is **γ-Lipschitz**, that is, such that $\sigma(f(x),f(y)) \le \gamma\rho(x,y)$ for all x, $y \in X$, where $\gamma \ge 0$. If $r > 0$ and $\theta^{(X)}_r$, $\theta^{(Y)}_r$ are the r-dimensional Hausdorff outer measures on X and Y respectively, then $\theta^{(Y)}_r f[A] \le \gamma^r \theta^{(X)}_r A$ for every $A \subseteq X$.

proof (Compare 264G.) Let $\delta > 0$. Set $\eta = \delta/(1+\gamma)$ and consider $\theta^{(X)}_{r\eta} : \mathcal{P}X \to [0,\infty]$, defined as in 471A. We know that $\theta^{(X)}_r A \ge \theta^{(X)}_{r\eta} A$, so there is a sequence $\langle D_n\rangle_{n\in\mathbb{N}}$ of sets, all of diameter at most η, covering A, with $\sum_{n=0}^{\infty}(\operatorname{diam} D_n)^r \le \theta^{(X)}_r A + \delta$. Now $\phi[A] \subseteq \bigcup_{n\in\mathbb{N}} \phi[D_n]$ and

$$\operatorname{diam}\phi[D_n] \le \gamma \operatorname{diam} D_n \le \gamma\eta \le \delta$$

for every n. Consequently

$$\theta^{(Y)}_{r\delta}(\phi[A]) \le \textstyle\sum_{n=0}^{\infty}(\operatorname{diam}\phi[D_n])^r \le \sum_{n=0}^{\infty}\gamma^r(\operatorname{diam} D_n)^r \le \gamma^r(\theta^{(X)}_r + \delta),$$

and

$$\theta^{(Y)}_r(\phi[A]) = \lim_{\delta\downarrow 0}\theta^{(Y)}_{r\delta}(\phi[A]) \le \gamma^r\theta^{(X)}_r A,$$

as claimed.

471K Lemma Let (X,ρ) be a metric space, and $r > 0$. Let μ_{Hr} be r-dimensional Hausdorff measure on X. If $A \subseteq X$, then $\mu_{Hr}A = 0$ iff for every $\epsilon > 0$ there is a countable family $\mathcal{D}$ of sets, covering A, such that $\sum_{D\in\mathcal{D}}(\operatorname{diam} D)^r \le \epsilon$.

proof If $\mu_{Hr}A = 0$ and $\epsilon > 0$, then, in the language of 471A, $\theta_{r1}A \le \epsilon$, so there is a sequence $\langle D_n\rangle_{n\in\mathbb{N}}$ of sets covering A such that $\sum_{n=0}^{\infty}(\operatorname{diam} D_n)^r \le \epsilon$.

If the condition is satisfied, then for any ϵ, $\delta > 0$ there is a countable family $\mathcal{D}$ of sets, covering A, such that $\sum_{D\in\mathcal{D}}(\operatorname{diam} D)^r \le \min(\epsilon,\delta^r)$. If $\mathcal{D}$ is infinite, enumerate it as $\langle D_n\rangle_{n\in\mathbb{N}}$; if it is finite, enumerate it as $\langle D_n\rangle_{n<m}$ and set $D_n = \emptyset$ for $n \ge m$. Now $A \subseteq \bigcup_{n\in\mathbb{N}} D_n$ and $\operatorname{diam} D_n \le \delta$ for every $n \in \mathbb{N}$, so $\theta_{r\delta}A \le \sum_{n=0}^{\infty}(\operatorname{diam} D_n)^r \le \epsilon$. As ϵ is arbitrary, $\theta_{r\delta}A = 0$; as δ is arbitrary, $\theta_r A = 0$; it follows at once that $\mu_{Hr}A$ is defined and is zero (113Xa).

471L Proposition Let (X,ρ) be a metric space and $0 < r < s$. If $A \subseteq X$ is such that $\mu^*_{Hr}A$ is finite, then $\mu^*_{Hs}A = 0$.

proof Let $\epsilon > 0$. Let $\delta > 0$ be such that $\delta^{s-r}(1 + \mu^*_{Hr}A) \le \epsilon$. Then there is a sequence $\langle A_n\rangle_{n\in\mathbb{N}}$ of sets of diameter at most δ such that $A \subseteq \bigcup_{n\in\mathbb{N}} A_n$ and $\sum_{n=0}^{\infty}(\operatorname{diam} A_n)^r \le 1 + \mu^*_{Hr}A$. But now, by the choice of δ, $\sum_{n=0}^{\infty}(\operatorname{diam} A_n)^s \le \epsilon$. As ϵ is arbitrary, $\mu_{Hs}A = 0$, by 471K.

471M There is a generalization of the density theorems of §§223 and 261 for general Hausdorff measures, which (as one expects) depends on a kind of Vitali theorem. I will use the following notation for the next few paragraphs.

Definition If (X,ρ) is a metric space and $A \subseteq X$, write $A^{\sim}$ for $\{x : x \in X, \rho(x,A) \le 2\operatorname{diam} A\}$, where $\rho(x,A) = \inf_{y\in A}\rho(x,y)$. (Following the conventions of 471A, $\emptyset^{\sim} = \emptyset$.)

471N Lemma Let (X,ρ) be a metric space. Let $\mathcal{F}$ be a family of subsets of X such that $\{\operatorname{diam} F : F \in \mathcal{F}\}$ is bounded. Set

$$Y = \bigcap_{\delta>0} \bigcup \{F : F \in \mathcal{F}, \operatorname{diam} F \leq \delta\}.$$

Then there is a disjoint family $\mathcal{I} \subseteq \mathcal{F}$ such that

(i) $\bigcup \mathcal{F} \subseteq \bigcup_{F\in\mathcal{I}} F^\sim$;

(ii) $Y \subseteq \overline{\bigcup \mathcal{J}} \cup \bigcup_{F\in\mathcal{I}\setminus\mathcal{J}} F^\sim$ for every finite $\mathcal{J} \subseteq \mathcal{I}$.

proof (a) Let γ be an upper bound for $\{\operatorname{diam} F : F \in \mathcal{F}\}$. Choose $\langle \mathcal{I}_n\rangle_{n\in\mathbb{N}}$, $\langle \mathcal{J}_n\rangle_{n\in\mathbb{N}}$ inductively, as follows. $\mathcal{I}_0 = \emptyset$. Given $\mathcal{I}_n$, set $\mathcal{F}'_n = \{F : F \in \mathcal{F}, \operatorname{diam} F \geq 2^{-n}\gamma, F \cap \bigcup \mathcal{I}_n = \emptyset\}$, and let $\mathcal{J}_n \subseteq \mathcal{F}'_n$ be a maximal disjoint set; now set $\mathcal{I}_{n+1} = \mathcal{I}_n \cup \mathcal{J}_n$, and continue.

At the end of the induction, set

$$\mathcal{I}' = \bigcup_{n\in\mathbb{N}} \mathcal{I}_n, \quad \mathcal{I} = \mathcal{I}' \cup \{\{x\} : x \in F \setminus \bigcup \mathcal{I}', \{x\} \in \mathcal{F}\}.$$

The construction ensures that every $\mathcal{I}_n$ is a disjoint subset of $\mathcal{F}$, so $\mathcal{I}'$ and $\mathcal{I}$ are also disjoint subfamilies of $\mathcal{F}$.

(b) ? Suppose, if possible, that there is a point x in $\bigcup \mathcal{F} \setminus \bigcup_{F\in\mathcal{I}} F^\sim$. Let $F \in \mathcal{F}$ be such that $x \in F$. Since $x \notin \bigcup \mathcal{I}'$ and $\{x\} \notin \mathcal{I}$, $\{x\} \notin \mathcal{F}$, and $\operatorname{diam} F > 0$; let $n \in \mathbb{N}$ be such that $2^{-n}\gamma \leq \operatorname{diam} F \leq 2^{-n+1}\gamma$. If $F \notin \mathcal{F}'_n$, there is a $D \in \mathcal{I}_n$ such that $F \cap D \neq \emptyset$; otherwise, since $\mathcal{J}_n$ is maximal and $F \notin \mathcal{J}_n$, there is a $D \in \mathcal{J}_n$ such that $F \cap D \neq \emptyset$. In either case, we have a $D \in \mathcal{I}$ such that $F \cap D \neq \emptyset$ and $\operatorname{diam} F \leq 2 \operatorname{diam} D$. But in this case $\rho(x, D) \leq \operatorname{diam} F \leq 2 \operatorname{diam} D$ and $x \in D^\sim$, which is impossible. **X**

(c) ? Suppose, if possible, that there are a point $x \in Y$ and a finite set $\mathcal{J} \subseteq \mathcal{I}$ such that $x \notin \overline{\bigcup \mathcal{J}} \cup \bigcup_{F\in\mathcal{I}\setminus\mathcal{J}} F^\sim$. Then there is an $F \in \mathcal{F}$ such that $x \in F$ and $\operatorname{diam} F < \rho(x, \bigcup \mathcal{J})$, so that $F \cap \bigcup \mathcal{J} = \emptyset$. As in (b), F cannot be $\{x\}$, and there must be an $n \in \mathbb{N}$ such that $2^{-n}\gamma < \operatorname{diam} F \leq 2^{-n+1}\gamma$. As in (b), there must be a $D \in \mathcal{I}_{n+1}$ such that $F \cap D \neq \emptyset$, so that $x \in D^\sim$; and as D cannot belong to $\mathcal{J}$, we again have a contradiction. **X**

471O Lemma Let (X,ρ) be a metric space, and $r > 0$. Let μ_{Hr} be r-dimensional Hausdorff measure on X. Suppose that A, $\mathcal{F}$ are such that

(i) $\mathcal{F}$ is a family of closed subsets of X such that $\sum_{n=0}^\infty (\operatorname{diam} F_n)^r$ is finite for every disjoint sequence $\langle F_n\rangle_{n\in\mathbb{N}}$ in $\mathcal{F}$,

(ii) for every $x \in A$, $\delta > 0$ there is an $F \in \mathcal{F}$ such that $x \in F$ and $0 < \operatorname{diam} F \leq \delta$.

Then there is a countable disjoint family $\mathcal{I} \subseteq \mathcal{F}$ such that $A \setminus \bigcup \mathcal{I}$ has zero r-dimensional Hausdorff measure.

proof Replacing $\mathcal{F}$ by $\{F : F \in \mathcal{F}, 0 < \operatorname{diam} F \leq 1\}$ if necessary, we may suppose that $\sup_{F\in\mathcal{F}} \operatorname{diam} F$ is finite and that $\operatorname{diam} F > 0$ for every $F \in \mathcal{F}$. Take a disjoint family $\mathcal{I} \subseteq \mathcal{F}$ as in 471N. If $\mathcal{I}$ is finite, then $A \subseteq Y \subseteq \bigcup \mathcal{I}$, where Y is defined as in 471N, so we can stop. Otherwise, hypothesis (i) tells us that $\{F : F \in \mathcal{I}, \operatorname{diam} F \geq \delta\}$ is finite for every $\delta > 0$, so $\mathcal{I}$ is countable; enumerate it as $\langle F_n\rangle_{n\in\mathbb{N}}$; we must have $\sum_{n=0}^\infty (\operatorname{diam} F_n)^r < \infty$. Since $\operatorname{diam} F_n^\sim \leq 5 \operatorname{diam} F_n$ for every n, $\sum_{n=0}^\infty (\operatorname{diam} F_n^\sim)^r$ is finite, and $\inf_{n\in\mathbb{N}} \sum_{i=n}^\infty (\operatorname{diam} F_i^\sim)^r = 0$. But now observe that the construction ensures that $A \setminus \bigcup \mathcal{I} \subseteq \bigcup_{i\geq n} F_i^\sim$ for every $n \in \mathbb{N}$. By 471K, $\mu_{Hr}(A \setminus \bigcup \mathcal{I}) = 0$, as required.

471P Theorem Let (X,ρ) be a metric space, and $r > 0$. Let μ_{Hr} be r-dimensional Hausdorff measure on X. Suppose that $A \subseteq X$ and $\mu^*_{Hr} A < \infty$.

(a) $\lim_{\delta\downarrow 0} \sup\{\frac{\mu^*_{Hr}(A\cap D)}{(\operatorname{diam} D)^r} : x \in D, 0 < \operatorname{diam} D \leq \delta\} = 1$ for μ_{Hr}-almost every $x \in A$.

(b) $\limsup_{\delta\downarrow 0} \frac{\mu^*_{Hr}(A\cap B(x,\delta))}{\delta^r} \geq 1$ for μ_{Hr}-almost every $x \in A$. So

$$2^{-r} \leq \limsup_{\delta\downarrow 0} \frac{\mu^*_{Hr}(A\cap B(x,\delta))}{(\operatorname{diam} B(x,\delta))^r} \leq 1$$

for μ_{Hr}-almost every $x \in A$.

(c) If A is measured by μ_{Hr}, then

$$\lim_{\delta\downarrow 0}\sup\{\tfrac{\mu^*_{Hr}(A\cap D)}{(\operatorname{diam} D)^r} : x\in D,\ 0<\operatorname{diam} D\le\delta\}=0$$

for μ_{Hr}-almost every $x\in X\setminus A$.

proof (a)(i) Note first that as the quantities

$$\sup\{\tfrac{\mu^*_{Hr}(A\cap D)}{(\operatorname{diam} D)^r} : x\in D,\ 0<\operatorname{diam} D\le\delta\}$$

decrease with δ, the limit is defined in $[0,\infty]$ for every $x\in X$. Moreover, since $\operatorname{diam} D=\operatorname{diam}\overline{D}$ and $\mu^*_{Hr}(A\cap\overline{D})\ge\mu^*_{Hr}(A\cap D)$ for every D,

$$\begin{aligned}\sup\{\tfrac{\mu^*_{Hr}(A\cap D)}{(\operatorname{diam} D)^r} &: x\in D\subseteq X,\ 0<\operatorname{diam} D\le\delta\}\\ &=\sup\{\tfrac{\mu^*_{Hr}(A\cap F)}{(\operatorname{diam} F)^r} : F\subseteq X \text{ is closed},\ x\in F,\ 0<\operatorname{diam} F\le\delta\}\end{aligned}$$

for every x and δ.

(ii) Fix ϵ for the moment, and set

$$A_\epsilon=\{x : x\in A,\ \lim_{\delta\downarrow 0}\sup\{\tfrac{\mu^*_{Hr}(A\cap D)}{(\operatorname{diam} D)^r} : x\in D,\ 0<\operatorname{diam} D\le\delta\}>1+\epsilon\}.$$

Then $\theta_{r\eta}(A)\le\mu^*_{Hr}A-\frac{\epsilon}{1+\epsilon}\mu^*_{Hr}A_\epsilon$ for every $\eta>0$, where $\theta_{r\eta}$ is defined in 471A. **P** Let $\mathcal{F}$ be the family

$$\{F : F\subseteq X \text{ is closed},\ 0<\operatorname{diam} F\le\eta,\ (1+\epsilon)(\operatorname{diam} F)^r\le\mu^*_{Hr}(A\cap F)\}.$$

Then every member of A_ϵ belongs to sets in $\mathcal{F}$ of arbitrarily small diameter. Also, if $\langle F_n\rangle_{n\in\mathbb{N}}$ is any disjoint sequence in $\mathcal{F}$,

$$\textstyle\sum_{n=0}^\infty(\operatorname{diam} F_n)^r\le\sum_{n=0}^\infty\mu^*_{Hr}(A\cap F_n)\le\mu^*_{Hr}A<\infty$$

because every F_n, being closed, is measured by μ_{Hr}. (If you like, $F_n\cap A$ is measured by the subspace measure on A for every n.) So 471O tells us that there is a countable disjoint family $\mathcal{I}\subseteq\mathcal{F}$ such that $A_\epsilon\setminus\bigcup\mathcal{I}$ is negligible, and $\mu^*_{Hr}A_\epsilon=\mu^*_{Hr}(A_\epsilon\cap\bigcup\mathcal{I})$.

Because $\theta_{r\eta}$ is an outer measure and $\theta_{r\eta}\le\mu^*_{Hr}$,

$$\theta_{r\eta}A\le\theta_{r\eta}(A\cap\bigcup\mathcal{I})+\theta_{r\eta}(A\setminus\bigcup\mathcal{I})\le\sum_{F\in\mathcal{I}}(\operatorname{diam} F)^r+\mu^*_{Hr}(A\setminus\bigcup\mathcal{I})$$

(because $\mathcal{I}$ is countable)

$$\begin{aligned}&\le\tfrac{1}{1+\epsilon}\mu^*_{Hr}(A\cap\bigcup\mathcal{I})+\mu^*_{Hr}(A\setminus\bigcup\mathcal{I})=\mu^*_{Hr}A-\tfrac{\epsilon}{1+\epsilon}\mu^*_{Hr}(A\cap\bigcup\mathcal{I})\\ &\le\mu^*_{Hr}A-\tfrac{\epsilon}{1+\epsilon}\mu^*_{Hr}(A_\epsilon\cap\bigcup\mathcal{I})=\mu^*_{Hr}A-\tfrac{\epsilon}{1+\epsilon}\mu^*_{Hr}A_\epsilon,\end{aligned}$$

as claimed. **Q**

(iii) Taking the supremum as $\eta\downarrow 0$, $\mu^*_{Hr}A\le\mu^*_{Hr}A-\frac{\epsilon}{1+\epsilon}\mu^*_{Hr}A_\epsilon$ and $\mu_{Hr}A_\epsilon=0$.

This is true for any $\epsilon>0$. But

$$\{x : x\in A,\ \lim_{\delta\downarrow 0}\sup\{\tfrac{\mu^*_{Hr}(A\cap D)}{(\operatorname{diam} D)^r} : x\in D,\ 0<\operatorname{diam} D\le\delta\}>1\}$$

is just $\bigcup_{n\in\mathbb{N}}A_{2^{-n}}$, so is negligible.

(iv) Next, for $0<\epsilon\le 1$, set

$$\begin{aligned}A'_\epsilon=\{x : x\in A,\ &\mu^*_{Hr}(A\cap D)\le(1-\epsilon)(\operatorname{diam} D)^r\\ &\text{whenever } x\in D \text{ and } 0<\operatorname{diam} D\le\epsilon\}.\end{aligned}$$

Then A'_ϵ is negligible. **P** Let $\langle D_n\rangle_{n\in\mathbb{N}}$ be any sequence of sets of diameter at most ϵ covering A'_ϵ. Set $K = \{n : D_n \cap A'_\epsilon \neq \emptyset\}$. Then

$$\begin{aligned}\mu^*_{Hr}A'_\epsilon &\leq \sum_{n\in K} \mu^*_{Hr}(A\cap D_n)\\ &\leq (1-\epsilon)\sum_{n\in K}(\operatorname{diam} D_n)^r \leq (1-\epsilon)\sum_{n=0}^{\infty}(\operatorname{diam} D_n)^r.\end{aligned}$$

As $\langle D_n\rangle_{n\in\mathbb{N}}$ is arbitrary,

$$\mu^*_{Hr}A'_\epsilon \leq (1-\epsilon)\theta_{r\epsilon}A'_\epsilon \leq (1-\epsilon)\mu^*_{Hr}A'_\epsilon,$$

and $\mu^*_{Hr}A'_\epsilon$ (being finite) must be zero. **Q**

This means that

$$\{x : x\in A,\ \lim_{\delta\downarrow 0}\sup\{\tfrac{\mu^*_{Hr}(A\cap D)}{(\operatorname{diam} D)^r} : x\in D,\ 0<\operatorname{diam} D\leq\delta\} < 1\} \subseteq \textstyle\bigcup_{n\in\mathbb{N}} A'_{2^{-n}}$$

is also negligible, and we have the result.

(b) We need a slight modification of the argument in (a)(iv). This time, for $0<\epsilon\leq 1$, set

$$\tilde{A}'_\epsilon = \{x : x\in A,\ \mu^*_{Hr}(A\cap B(x,\delta)) \leq (1-\epsilon)\delta^r \text{ whenever } 0<\delta\leq\epsilon\}.$$

Then $\mu^*_{Hr}\tilde{A}'_\epsilon \leq \epsilon$. **P** Note first that, as $\mu_{Hr}\{x\} = 0$ for every x, $\mu^*_{Hr}(A\cap B(x,\delta)) \leq (1-\epsilon)\delta^r$ whenever $x\in\tilde{A}'_\epsilon$ and $0\leq\delta\leq\epsilon$. Let $\langle D_n\rangle_{n\in\mathbb{N}}$ be a sequence of sets of diameter at most ϵ covering $\tilde{A}'_\epsilon$. Set $K = \{n : D_n\cap\tilde{A}'_\epsilon\neq\emptyset\}$, and for $n\in K$ choose $x_n\in D_n\cap\tilde{A}'_\epsilon$ and set $\delta_n = \operatorname{diam} D_n$. Then $D_n\subseteq B(x_n,\delta_n)$ and $\delta_n\leq\epsilon$ for each n, so $\tilde{A}'_\epsilon\subseteq\bigcup_{n\in K}B(x_n,\delta_n)$ and

$$\begin{aligned}\mu^*_{Hr}\tilde{A}'_\epsilon &\leq \sum_{n\in K}\mu^*_{Hr}(\tilde{A}'_\epsilon\cap B(x_n,\delta_n))\\ &\leq \sum_{n\in K}(1-\epsilon)\delta_n^r \leq (1-\epsilon)\sum_{n=0}^{\infty}(\operatorname{diam} D_n)^r.\end{aligned}$$

As $\langle D_n\rangle_{n\in\mathbb{N}}$ is arbitrary, $\mu^*_{Hr}\tilde{A}'_\epsilon\leq(1-\epsilon)\mu^*_{Hr}\tilde{A}'_\epsilon$ and $\tilde{A}'_\epsilon$ must be negligible. **Q**

Now

$$\{x : x\in A,\ \limsup_{\delta\downarrow 0}\tfrac{\mu^*_{Hr}(A\cap B(x,\delta))}{\delta^r} < 1\} = \textstyle\bigcup_{n\in\mathbb{N}}\tilde{A}'_{2^{-n}}$$

is negligible. As for the second formula, we need note only that $\operatorname{diam} B(x,\delta)\leq 2\delta$ for every $x\in X$, $\delta>0$ to obtain the first inequality, and apply (a) to obtain the second.

(c) Let $\epsilon>0$. This time, write $\tilde{A}_\epsilon$ for

$$\{x : x\in X,\ \lim_{\delta\downarrow 0}\sup\{\tfrac{\mu^*_{Hr}(A\cap D)}{(\operatorname{diam} D)^r} : x\in D,\ 0<\operatorname{diam} D\leq\delta\} > \epsilon\}.$$

Let $E\subseteq A$ be a closed set such that $\mu(A\setminus E)\leq\epsilon^2$ (471De). For $\eta>0$, let $\mathcal{F}_\eta$ be the family

$$\{F : F\subseteq X\setminus E \text{ is closed},\ 0<\operatorname{diam} F\leq\eta,\ \mu_{Hr}(A\cap F)\geq\epsilon(\operatorname{diam} F)^r\}.$$

Just as in (a) above, every point in $\tilde{A}_\epsilon\setminus E$ belongs to members of $\mathcal{F}_\eta$ of arbitrarily small diameter. If $\langle F_n\rangle_{n\in\mathbb{N}}$ is a disjoint sequence in $\mathcal{F}_\eta$,

$$\textstyle\sum_{n=0}^{\infty}(\operatorname{diam} F)^r \leq \frac{1}{\epsilon}\mu_{Hr}(A\setminus E)\leq\epsilon$$

is finite. There is therefore a countable disjoint family $\mathcal{I}_\eta\subseteq\mathcal{F}_\eta$ such that $\mu_{Hr}((\tilde{A}_\epsilon\setminus E)\setminus\bigcup\mathcal{I}_\eta) = 0$. If $\theta_{r\eta}$ is the outer measure defined in 471A, we have

$$\begin{aligned}\theta_{r\eta}(\tilde{A}_\epsilon\setminus A) &\leq \theta_{r\eta}(\textstyle\bigcup\mathcal{I}_\eta) + \theta_{r\eta}(\tilde{A}_\epsilon\setminus(E\cup\bigcup\mathcal{I}_\eta))\\ &\leq \sum_{F\in\mathcal{I}_\eta}(\operatorname{diam} F)^r + \mu^*_{Hr}(\tilde{A}_\epsilon\setminus(E\cup\textstyle\bigcup\mathcal{I}_\eta)) \leq \epsilon.\end{aligned}$$

As η is arbitrary, $\mu^*_{Hr}(\tilde{A}_\epsilon \setminus A) \leq \epsilon$. But now

$$\{x : x \in X \setminus A,\ \lim_{\delta \downarrow 0} \sup\{\tfrac{\mu^*_{Hr}(A \cap D)}{(\operatorname{diam} D)^r} : x \in D,\ 0 < \operatorname{diam} D \leq \delta\} > 0\}$$

is $\bigcup_{n \in \mathbb{N}} \tilde{A}_{2^{-n}} \setminus A$, and is negligible.

471Q I now come to a remarkable fact about Hausdorff measures on analytic spaces: their Borel versions are semi-finite (471S). We need some new machinery.

Lemma Let (X, ρ) be a metric space, and $r > 0$, $\delta > 0$. Suppose that $\theta_{r\delta}(X)$, as defined in 471A, is finite.

(a) There is a non-negative additive functional ν on $\mathcal{P}X$ such that $\nu X = 5^{-r}\theta_{r\delta}(X)$ and $\nu A \leq (\operatorname{diam} A)^r$ whenever $A \subseteq X$ and $\operatorname{diam} A \leq \frac{1}{5}\delta$.

(b) If X is compact, there is a Radon measure μ on X such that $\mu X = 5^{-r}\theta_{r\delta}(X)$ and $\mu G \leq (\operatorname{diam} G)^r$ whenever $G \subseteq X$ is open and $\operatorname{diam} G \leq \frac{1}{5}\delta$.

proof (a) I use 391E. If $\theta_{r\delta}(X) = 0$ the result is trivial. Otherwise, set $\gamma = 5^r/\theta_{r\delta}(X)$ and define $\phi : \mathcal{P}X \to [0,1]$ by setting $\phi A = \min(1, \gamma(\operatorname{diam} A)^r)$ if $\operatorname{diam} A \leq \frac{1}{5}\delta$, 1 for other $A \subseteq X$. Now

whenever $\langle A_i \rangle_{i \in I}$ is a finite family of subsets of X, $m \in \mathbb{N}$ and $\sum_{i \in I} \chi A_i \geq m\chi X$, then $\sum_{i \in I} \phi A_i \geq m$.

P Discarding any A_i for which $\phi A_i = 1$, if necessary, we may suppose that $\operatorname{diam} A_i \leq \frac{1}{5}\delta$ and $\phi A_i = \gamma(\operatorname{diam} A_i)^r$ for every i. Choose $\langle I_j \rangle_{j \leq m}$, $\langle J_j \rangle_{j < m}$ inductively, as follows. $I_0 = I$. Given that $j < m$ and that $I_j \subseteq I$ is such that $\sum_{i \in I_j} \chi A_i \geq (m-j)\chi X$, apply 471N to $\{A_i : i \in I_j\}$ to find $J_j \subseteq I_j$ such that $\langle A_i \rangle_{i \in J_j}$ is disjoint and $\bigcup_{i \in I_j} A_i \subseteq \bigcup_{i \in J_j} A_j^\sim$. Set $I_{j+1} = I_j \setminus J_j$. Observe that $\sum_{i \in J_j} \chi A_j \leq \chi X$, so $\sum_{i \in I_{j+1}} \chi A_i \geq (m-j-1)\chi X$ and the induction proceeds.

Now note that, for each $j < m$, $\langle A_i^\sim \rangle_{i \in J_j}$ is a cover of $\bigcup_{i \in I_j} A_i = X$ by sets of diameter at most δ. So $\sum_{i \in J_j} (\operatorname{diam} A_i^\sim)^r \geq \theta_{r\delta}(X)$ for each j, and $\sum_{i \in I} (\operatorname{diam} A_i^\sim)^r \geq m\theta_{r\delta}(X)$. Accordingly

$$\begin{aligned}\sum_{i \in I} \phi A_i &= \gamma \sum_{i \in I} (\operatorname{diam} A_i)^r \geq 5^{-r}\gamma \sum_{i \in I} (\operatorname{diam} A_i^\sim)^r \\ &\geq 5^{-r} m \gamma \theta_{r\delta}(X) = m. \ \blacksquare\end{aligned}$$

By 391E, there is an additive functional $\nu_0 : \mathcal{P}X \to [0,1]$ such that $\nu_0 X = 1$ and $\nu_0 A \leq \phi A$ for every $A \subseteq X$. Setting $\nu = 5^{-r}\theta_{r\delta}(X)\nu_0$, we have the result.

(b) Now suppose that X is compact. By 416N, there is a Radon measure μ on X such that $\mu X \leq \nu X$ and $\mu K \geq \nu K$ for every compact $K \subseteq X$. Because X itself is compact, $\mu X = \nu X = 5^{-r}\theta_{r\delta}(X)$. If G is open and $\operatorname{diam} G \leq \frac{1}{5}\delta$,

$$\begin{aligned}\mu G &= \mu X - \mu(X \setminus G) \leq \nu X - \nu(X \setminus G) \\ &\text{(because } X \setminus G \text{ is compact)} \\ &= \nu G \leq (\operatorname{diam} G)^r,\end{aligned}$$

as required.

471R Lemma (Howroyd 95) Let (X, ρ) be a compact metric space and $r > 0$. Let μ_{Hr} be r-dimensional Hausdorff measure on X. If $\mu_{Hr}(X) > 0$, there is a Borel set $H \subseteq X$ such that $0 < \mu_{Hr} H < \infty$.

proof (a) Let $\delta > 0$ be such that $\theta_{r,5\delta}(X) > 0$, where $\theta_{r,5\delta}$ is defined as in 471A. Then there is a family $\mathcal{V}$ of open subsets of X such that (i) $\operatorname{diam} V \leq \delta$ for every $V \in \mathcal{V}$ (ii) $\{V : V \in \mathcal{V}, \operatorname{diam} V \geq \epsilon\}$ is finite for every $\epsilon > 0$ (iii) whenever $A \subseteq X$ and $0 < \operatorname{diam} A < \frac{1}{4}\delta$ there is a $V \in \mathcal{V}$ such that $A \subseteq V$ and $\operatorname{diam} V \leq 8 \operatorname{diam} A$. **P** For each $k \in \mathbb{N}$, let I_k be a finite subset of X such that $X = \bigcup_{x \in I_k} B(x, 2^{-k-2}\delta)$; now set $\mathcal{V} = \{U(x, 2^{-k-1}\delta) : k \in \mathbb{N}, x \in I_k\}$. Then $\mathcal{V}$ is a family of open sets and (i) and (ii) are satisfied. If $A \subseteq X$ and $0 < \operatorname{diam} A < \frac{1}{4}\delta$, let $k \in \mathbb{N}$ be such that $2^{-k-3}\delta \leq \operatorname{diam} A < 2^{-k-2}\delta$. Take $x \in I_k$ such that $B(x, 2^{-k-2}\delta) \cap A \neq \emptyset$; then $A \subseteq U(x, 2^{-k-1}\delta) \in \mathcal{V}$ and $\operatorname{diam} U(x, 2^{-k-1}\delta) \leq 2^{-k}\delta \leq 8 \operatorname{diam} A$. $\blacksquare$

In particular, $\{V : V \in \mathcal{V}, \operatorname{diam} V \leq \epsilon\}$ covers X for every $\epsilon > 0$.

(b) Set

$$P = \{\mu : \mu \text{ is a Radon measure on } X, \mu V \leq (\operatorname{diam} V)^r \text{ for every } V \in \mathcal{V}\}.$$

P is non-empty (it contains the zero measure, for instance). Now if $G \subseteq X$ is open, $\mu \mapsto \mu G$ is lower semi-continuous for the narrow topology (437Jd), so P is a closed set in the narrow topology on the set of Radon measures on X, which may be identified with a compact subset of $C(X)^*$ with its weak* topology (437Kc). Moreover, since there is a finite subfamily of $\mathcal{V}$ covering X, $\gamma = \sup\{\mu X : \mu \in P\}$ is finite, and P is compact (437O). Because $\mu \mapsto \mu X$ is continuous, $P_0 = \{\mu : \mu \in P, \mu X = \gamma\}$ is non-empty. Of course P and P_0 are both convex, and P_0, like P, is compact. By the Kreĭn-Mil'man theorem (4A4Gb), applied in $C(X)^*$, P has an extreme point ν say.

Note next that $\theta_{r,5\delta}(X)$ is certainly finite, again because X is compact. By 471Qb, $\gamma > 0$, and ν is non-trivial. For any $\epsilon > 0$, there is a finite cover of X by sets in $\mathcal{V}$ of diameter at most ϵ, which have measure at most ϵ^r (for ν); so ν is atomless. In particular, $\nu\{x\} = 0$ for every $x \in X$.

(c) For $\epsilon > 0$, set

$$G_\epsilon = \bigcup\{V : V \in \mathcal{V}, 0 < \operatorname{diam} V \leq \epsilon \text{ and } \nu V \geq \tfrac{1}{2}(\operatorname{diam} V)^r\}.$$

Then G_ϵ is ν-conegligible. **P?** Otherwise, $\nu(X \setminus G_\epsilon) > 0$. Because $\mathcal{V}'_\epsilon = \{V : V \in \mathcal{V}, \operatorname{diam} V > \epsilon\}$ is finite, there is a Borel set $E \subseteq X \setminus G_\epsilon$ such that $\nu E > 0$ and, for every $V \in \mathcal{V}'_\epsilon$, either $E \subseteq V$ or $E \cap V = \emptyset$. Because ν is atomless, there is a measurable set $E_0 \subseteq E$ such that $\nu E_0 = \frac{1}{2}\nu E$ (215D); set $E_1 = E \setminus E_0$.

Define Radon measures ν_1, ν_2 on X by setting

$$\nu_i(F) = 2\nu(F \cap E_i) + \nu(F \setminus E)$$

whenever ν measures $F \setminus E_{1-i}$, for each i (use 416S if you feel the need to check that this defines a Radon measure on the definitions of this book). If $V \in \mathcal{V}$, then, by the choice of E,

either $E \subseteq V$ and $\nu_i V = \nu V \leq (\operatorname{diam} V)^r$

or $E \cap V = \emptyset$ and $\nu_i V = \nu V \leq (\operatorname{diam} V)^r$

or $0 < \operatorname{diam} V \leq \epsilon$ and $\nu V < \frac{1}{2}(\operatorname{diam} V)^r$, in which case $\nu_i V \leq 2\nu V \leq (\operatorname{diam} V)^r$

or $\operatorname{diam} V = 0$ and $\nu_i V = \nu V = 0 = (\operatorname{diam} V)^r$.

So both ν_i belong to P and therefore to P_0, since $\nu_i X = \nu X = \gamma$. But $\nu = \frac{1}{2}(\nu_1 + \nu_2)$ and $\nu_1 \neq \nu_2$, so this is impossible, because ν is supposed to be an extreme point of P_0. **XQ**

(d) Accordingly, setting $H = \bigcap_{n\in\mathbb{N}} G_{2^{-n}}$, $\nu H = \nu X = \gamma$. Now examine $\mu_{Hr} H$.

(i) $\mu_{Hr} H \geq 8^{-r}\gamma$. **P** Let $\langle A_n\rangle_{n\in\mathbb{N}}$ be a sequence of sets covering H with $\operatorname{diam} A_n \leq \frac{1}{8}\delta$ for every n. Set $K = \{n : \operatorname{diam} A_n > 0\}$, $H' = H \cap \bigcup_{n\in K} A_n$; then $H \setminus H'$ is countable, so $\nu H' = \nu H$. For each $n \in K$, let $V_n \in \mathcal{V}$ be such that $A_n \subseteq V_n$ and $\operatorname{diam} V_n \leq 8 \operatorname{diam} A_n$ ((a) above). Then

$$\begin{aligned}\sum_{n=0}^{\infty} (\operatorname{diam} A_n)^r &= \sum_{n\in K} (\operatorname{diam} A_n)^r \geq 8^{-r} \sum_{n\in K} (\operatorname{diam} V_n)^r \\ &\geq 8^{-r} \sum_{n\in K} \nu V_n \geq 8^{-r} \nu H' = 8^{-r}\gamma.\end{aligned}$$

As $\langle A_n\rangle_{n\in\mathbb{N}}$ is arbitrary,

$$8^{-r}\gamma \leq \theta_{r,\delta/8}(H) \leq \mu^*_{Hr} H = \mu_{Hr} H. \ \textbf{Q}$$

(ii) $\mu_{Hr} H \leq 2\gamma$. **P** Let $\eta > 0$. Set $\mathcal{F} = \{\overline{V} : V \in \mathcal{V}, 0 < \operatorname{diam} V \leq \eta, \nu V \geq \frac{1}{2}(\operatorname{diam} V)^r\}$. Then $\mathcal{F}$ is a family of closed subsets of X, and (by the definition of G_ϵ) every member of H belongs to members of $\mathcal{F}$ of arbitrarily small diameter. Also $\nu F \geq \frac{1}{2}(\operatorname{diam} F)^r$ for every $F \in \mathcal{F}$, so

$$\textstyle\sum_{n=0}^{\infty} (\operatorname{diam} F_n)^r \leq 2 \sum_{n=0}^{\infty} \nu F_n < \infty$$

for any disjoint sequence $\langle F_n\rangle_{n\in\mathbb{N}}$ in $\mathcal{F}$. By 471O, there is a countable disjoint family $\mathcal{I} \subseteq \mathcal{F}$ such that $\mu_{Hr}(H \setminus \bigcup \mathcal{I}) = 0$. Accordingly

$$\theta_{r\eta}(H) \leq \sum_{F\in\mathcal{I}}(\operatorname{diam} F)^r + \theta_{r\eta}(H \setminus \bigcup\mathcal{I}) \leq \sum_{F\in\mathcal{I}} 2\nu F \leq 2\gamma.$$

As η is arbitrary, $\mu_{Hr}H = \mu^*_{Hr}H \leq 2\gamma$. **Q**

(e) But this means that we have found a Borel set H with $0 < \mu_{Hr}H < \infty$, as required.

471S Theorem (HOWROYD 95) Let (X, ρ) be an analytic metric space, and $r > 0$. Let μ_{Hr} be r-dimensional Hausdorff measure on X, and $\mathcal{B}$ the Borel σ-algebra of X. Then the Borel measure $\mu_{Hr}\restriction\mathcal{B}$ is semi-finite and tight (that is, inner regular with respect to the compact sets).

proof Suppose that $E \in \mathcal{B}$ and $\mu_{Hr}E > 0$. Since E is analytic (423E), 471I above tells us that there is a compact set $K \subseteq E$ such that $\mu_{Hr}K > 0$. Next, by 471R, there is a Borel set $H \subseteq K$ such that $0 < \mu_{Hr}H < \infty$. (Strictly speaking, $\mu_{Hr}H$ here should be calculated as the r-dimensional Hausdorff measure of H defined by the subspace metric $\rho\restriction K \times K$ on K. By 471E we do not need to distinguish between this and the r-dimensional measure calculated from ρ itself.) By 471I again (applied to the subspace metric on H), there is a compact set $L \subseteq H$ such that $\mu_{Hr}L > 0$.

Thus E includes a non-negligible compact set of finite measure. As E is arbitrary, this is enough to show both that $\mu_{Hr}\restriction\mathcal{B}$ is semi-finite and that it is tight.

471X Basic exercises (a) Define a metric ρ on $X = \{0,1\}^{\mathbb{N}}$ by setting $\rho(x,y) = 2^{-n}$ if $x\restriction n = y\restriction n$ and $x(n) \neq y(n)$. Show that the usual measure μ on X is one-dimensional Hausdorff measure. (*Hint*: $\operatorname{diam} F \geq \mu F$ for every closed set $F \subseteq X$.)

(b) Let (X, ρ) be a metric space and $r > 0$; let μ_{Hr}, $\theta_{r\infty}$ be r-dimensional Hausdorff measure and capacity on X. (i) Show that, for $A \subseteq X$, $\mu_{Hr}A = 0$ iff $\theta_{r\infty}A = 0$. (ii) Suppose that $E \subseteq X$ and $\delta > 0$ are such that $\mu_{Hr}E < \infty$ and $\delta < \theta_{r\infty}E$. Show that there is a closed set $F \subseteq E$ such that $\mu_{Hr}F > 0$ and $\delta\mu_{Hr}(F \cap G) \leq (\operatorname{diam} G)^r$ whenever μ_{Hr} measures G. (*Hint*: show that $\{G^\bullet : \theta_{r\infty}G \leq \delta\mu_{Hr}(E \cap G)\}$ cannot be order-dense in the measure algebra of μ_{Hr}. This is a version of 'Frostman's Lemma'.)

(c) Let (X, ρ) be an analytic metric space, (Y, σ) a metric space, and $f : X \to Y$ a Lipschitz function, that is, a function which is γ-Lipschitz for some $\gamma \geq 0$. Show that if $r > 0$ and $A \subseteq X$ is measured by Hausdorff r-dimensional measure on X, with finite measure, then $f[A]$ is measured by Hausdorff r-dimensional measure on Y.

(d) Let (X, ρ) be a metric space and $r > 0$. Show that a set $A \subseteq X$ is negligible for Hausdorff r-dimensional measure on X iff there is a sequence $\langle A_n\rangle_{n\in\mathbb{N}}$ of subsets of X such that $\sum_{n=0}^{\infty}(\operatorname{diam} A_n)^r$ is finite and $A \subseteq \bigcap_{n\in\mathbb{N}}\bigcup_{m\geq n} A_m$.

(e) Let (X, ρ) be a metric space. (i) Show that there is a unique $\dim_H(X) \in [0,\infty]$ such that the r-dimensional Hausdorff measure of X is infinite if $0 < r < \dim_H(X)$, zero if $r > \dim_H(X)$. ($\dim_H(X)$ is the **Hausdorff dimension** of X.) (ii) Show that if $\langle A_n\rangle_{n\in\mathbb{N}}$ is any sequence of subsets of X, then $\dim_H(\bigcup_{n\in\mathbb{N}} A_n) = \sup_{n\in\mathbb{N}} \dim_H(A_n)$.

(f) Let (X, ρ) be a metric space, and μ any topological measure on X. Suppose that $E \subseteq X$ and that μE is defined and finite. (i) Show that $(x,\delta) \mapsto \mu(E \cap B(x,\delta)) : X \times [0,\infty[\to \mathbb{R}$ is upper semi-continuous. (ii) Show that $x \mapsto \limsup_{\delta\downarrow 0} \frac{1}{\delta^r}\mu(E \cap B(x,\delta)) : X \to [0,\infty]$ is Borel measurable. (iii) Show that if X is separable, then $\mu B(x,\delta) > 0$ for every $\delta > 0$, for almost every $x \in X$.

(g) Give $\mathbb{R}$ its usual metric. Let $C \subseteq \mathbb{R}$ be the Cantor set, and $r = \ln 2/\ln 3$. Show that

$$\liminf_{\delta\downarrow 0} \frac{\mu_{Hr}(C\cap B(x,\delta))}{(\operatorname{diam} B(x,\delta))^r} \leq 2^{-r}$$

for every $x \in \mathbb{R}$.

(h) Let (X, ρ) be a metric space and $r > 0$. Let μ_{Hr} be r-dimensional Hausdorff measure on X and $\tilde{\mu}_{Hr}$ its c.l.d. version (213D-213E). Show that $\tilde{\mu}_{Hr}$ is inner regular with respect to the closed sets, and that $\tilde{\mu}_{Hr}A = \mu_{Hr}A$ for every analytic set $A \subseteq X$.

471Y Further exercises (a) The next few exercises (down to 471Yd) will all be based on the following context. Let (X,ρ) be a metric space and $\psi : \mathcal{P}X \to [0,\infty]$ a function such that $\psi\emptyset = 0$ and $\psi A \leq \psi A'$ whenever $A \subseteq A' \subseteq X$. Set

$$\theta_{\psi\delta}A = \inf\{\sum_{n=0}^{\infty} \psi D_n : \langle D_n\rangle_{n\in\mathbb{N}} \text{ is a sequence of subsets of } X \text{ covering } A,$$
$$\operatorname{diam} D_n \leq \delta \text{ for every } n \in \mathbb{N}\}$$

for $\delta > 0$, and $\theta_\psi A = \sup_{\delta>0} \theta_{\psi\delta}A$ for $A \subseteq X$ Show that θ_ψ is a metric outer measure. Let μ_ψ be the measure defined from θ_ψ by Carathéodory's method.

(b) Suppose that $\psi A = \inf\{\psi E : E \text{ is a Borel set including } A\}$ for every $A \subseteq X$. Show that $\theta_\psi = \mu_\psi^*$ and that $\mu_\psi E = \sup\{\mu_\psi F : F \subseteq E \text{ is closed}\}$ whenever $\mu_\psi E < \infty$.

(c) Suppose that X is separable and that there is a $\beta \geq 0$ such that $\psi A^\sim \leq \beta\psi A$ for every $A \subseteq X$, where $A^\sim$ is defined in 471M. (i) Suppose that $A \subseteq X$ and $\mathcal{F}$ is a family of closed subsets of X such that $\sum_{n=0}^{\infty} \psi F_n$ is finite for every disjoint sequence $\langle F_n\rangle_{n\in\mathbb{N}}$ in $\mathcal{F}$ and for every $x \in A$, $\delta > 0$ there is an $F \in \mathcal{F}$ such that $x \in F$ and $0 < \operatorname{diam} F \leq \delta$. Show that there is a disjoint family $\mathcal{I} \subseteq \mathcal{F}$ such that $\mu_\psi(A \setminus \bigcup\mathcal{I}) = 0$. (ii) Suppose that $\delta > 0$ and that $\theta_{\psi\delta}(X) < \infty$. Show that there is a non-negative additive functional ν on $\mathcal{P}X$ such that $\nu X = \frac{1}{\beta}\theta_{\psi\delta}(X)$ and $\nu A \leq \psi A$ whenever $A \subseteq X$ and $\operatorname{diam} A \leq \frac{1}{5}\delta$. (iii) Now suppose that for every $x \in X$, $\epsilon > 0$ there is a $\delta > 0$ such that $\psi B(x,\delta) \leq \epsilon$. Show that if X is compact and $\mu_\psi X > 0$ there is a compact set $K \subseteq X$ such that $0 < \mu_\psi K < \infty$.

(d) State and prove a version of 471P appropriate to this context.

(e) Give an example of a set $A \subseteq \mathbb{R}^2$ which is measured by Hausdorff 1-dimensional measure on $\mathbb{R}^2$ but is such that its projection onto the first coordinate is not measured by Hausdorff 1-dimensional measure on $\mathbb{R}$.

(f) Show that the space (X,ρ) of 471Xa can be isometrically embedded as a subset of a metric space (Y,σ) in such a way that (i) $\operatorname{diam} B(y,\delta) = 2\delta$ for every $y \in Y$ and $\delta \geq 0$ (ii) $Y \setminus X$ is countable. Show that if μ_{H1} is one-dimensional Hausdorff measure on Y, then $\mu_{H1}B(y,\delta) \leq \delta$ for every $y \in Y$, $\delta \geq 0$, so that

$$\limsup_{\delta\downarrow 0} \frac{\mu_{H1}B(y,\delta)}{\operatorname{diam} B(x,\delta)} = \frac{1}{2}$$

for every $y \in Y$.

(g) Let $\langle k_n\rangle_{n\in\mathbb{N}}$ be a sequence in $\mathbb{N} \setminus \{0,1,2,3\}$ such that $\sum_{n=0}^{\infty} \frac{1}{k_n} < \infty$. Set $X = \prod_{n\in\mathbb{N}} k_n$. Set $m_0 = 1$, $m_{n+1} = k_0k_1\dots k_n$ for $n \in \mathbb{N}$. Define a metric ρ on X by saying that

$$\rho(x,y) = 1/2m_n \text{ if } n = \min\{i : x(i) \neq y(i)\} \text{ and } \min(x(n),y(n)) = 0,$$
$$= 1/m_n \text{ if } n = \min\{i : x(i) \neq y(i)\} \text{ and } \min(x(n),y(n)) > 0.$$

Let ν be the product measure on X obtained by giving each factor k_n the uniform probability measure in which each singleton set has measure $1/k_n$. (i) Show that if $A \subseteq X$ then $\nu^* A \leq \operatorname{diam} A$. (ii) Show that ν is one-dimensional Hausdorff measure on X. (iii) Set $E = \bigcup_{n\in\mathbb{N}}\{x : x \in X, x(n) = 0\}$. Show that $\nu E < 1$. (iv) Show that

$$\limsup_{\delta\downarrow 0} \frac{\nu(E\cap B(x,\delta))}{\nu B(x,\delta)} \geq \frac{1}{2}$$

for every $x \in X$. (v) Show that there is a family $\mathcal{F}$ of closed balls in X such that every point of X is the centre of arbitrarily small members of $\mathcal{F}$, but $\nu(\bigcup\mathcal{I}) < 1$ for any disjoint subfamily $\mathcal{I}$ of $\mathcal{F}$.

(h) Let ρ be the metric on $\{0,1\}^{\mathbb{N}}$ defined in 471Xa. Show that for any integer $s \geq 1$ there is a bijection $f : [0,1]^s \to \{0,1\}^{\mathbb{N}}$ such that whenever $0 < r \leq s$, μ_{Hr}^* is Hausdorff r-dimensional outer measure on $[0,1]^s$ (for its usual metric) and $\tilde{\mu}_{H,r/s}^*$ is Hausdorff $\frac{r}{s}$-dimensional measure on $\{0,1\}^\omega$, then there is an $\alpha > 0$ such that $\mu_{Hr}^* f^{-1}[A] \leq \mu_{H,r/s}^* A \leq \alpha\mu_{Hr}^* f^{-1}[A]$ for every $A \subseteq \{0,1\}^{\mathbb{N}}$.

(i) Let (X, ρ) be a metric space, and $r > 0$; let $s \geq 1$ be an integer. Write $\mu_{Hr}^{(X)}$ and $\mu_{H,r+s}^{(X\times\mathbb{R}^s)}$ for Hausdorff r-dimensional measure on X and Hausdorff $r+s$-dimensional measure on $X \times \mathbb{R}^s$ respectively, and μ_{Ls} for Lebesgue measure on $\mathbb{R}^s$. (i) Show that there are non-zero constants c, c' such that $c\mu_{H,r+s}^{(X\times\mathbb{R}^s)}(E \times F) \leq \mu_{Hr}^{(X)}(E) \cdot \mu_{Ls}(F) \leq c'\mu_{H,r+s}^{(X\times\mathbb{R}^s)}(E \times F)$ for all Borel sets $E \subseteq X$, $F \subseteq \mathbb{R}^s$. (*Hint*: Federer 69, 2.10.45.) (ii) Write λ for the c.l.d. product of $\mu_{Hr}^{(X)}$ and μ_{Ls}, and $\tilde{\mu}_{H,r+s}^{(X\times\mathbb{R}^s)}$ for the c.l.d. version of $\mu_{H,r+s}^{(X\times\mathbb{R}^s)}$. Show that these have the same domain Λ and that $c\tilde{\mu}_{H,r+s}^{(X\times\mathbb{R}^s)}(W) \leq \lambda W \leq c'\tilde{\mu}_{H,r+s}^{(X\times\mathbb{R}^s)}(W)$ for every $W \in \Lambda$.

471 Notes and comments In the exposition above, I have worked throughout with simple r-dimensional measures for $r > 0$. As noted in 264Db, there are formulae in which it is helpful to interpret μ_{H0} as counting measure. More interestingly, when we come to use Hausdorff measures to give us information about the geometric structure of an object (e.g., in the observation that the Cantor set has $\ln 2 / \ln 3$-dimensional Hausdorff measure 1, in 264J), it is sometimes useful to refine the technique by using other functionals than $A \mapsto (\operatorname{diam} A)^r$ in the basic formulae of 264A or 471A. The most natural generalization is to functionals of the form $\psi A = h(\operatorname{diam} A)$ where $h : [0, \infty] \to [0, \infty]$ is a non-decreasing function (264Yo). But it is easy to see that many of the arguments are valid in much greater generality, as in 471Ya-471Yc. For more in these directions see Rogers 70 and Federer 69.

In the context of this book, the most conspicuous peculiarity of Hausdorff measures is that they are often very far from being semi-finite. (This is trivial for non-separable spaces, by 471Df. That Hausdorff one-dimensional measure on a subset of $\mathbb{R}^2$ can be purely infinite is not I think obvious; I gave an example in 439H.) The response I ordinarily recommend in such cases is to take the c.l.d. version. But then of course we need to know just what effect this will have. In geometric applications, one usually begins by checking that the sets one is interested in have σ-finite measure, and that therefore no problems arise; but it is a striking fact that Hausdorff measures behave relatively well on analytic sets, even when not σ-finite, provided we ask exactly the right questions (471I, 471S, 471Xh).

The geometric applications of Hausdorff measures, naturally, tend to rely heavily on density theorems; it is therefore useful to know that we have effective versions of Vitali's theorem available in this context (471N-471O), leading to a general density theorem (471P) similar to that in 261D; see also 472D below. I note that 471P is useful only after we have been able to concentrate our attention on a set of finite measure. And traps remain. For instance, the formulae of 261C-261D cannot be transferred to the present context without re-evaluation (471Yg).

472 Besicovitch's Density Theorem

The first step in the program of the next few sections is to set out some very remarkable properties of Euclidean space. We find that in $\mathbb{R}^r$, for geometric reasons (472A), we have versions of Vitali's theorem (472B-472C) and Lebesgue's Density Theorem (472D) for arbitrary Radon measures. I add a version of the Hardy-Littlewood Maximal Theorem (472F).

Throughout the section, $r \geq 1$ will be a fixed integer. As usual, I write $B(x, \delta)$ for the closed ball with centre x and radius δ. $\| \|$ will represent the Euclidean norm, and $x \cdot y$ the scalar product of x and y, so that $x \cdot y = \sum_{i=1}^r \xi_i \eta_i$ if $x = (\xi_1, \dots, \xi_r)$ and $y = (\eta_1, \dots, \eta_r)$.

472A Besicovitch's Covering Lemma Suppose that $\epsilon > 0$ is such that $(5^r + 1)(1 - \epsilon - \epsilon^2)^r > (5 + \epsilon)^r$. Let $x_0, \dots, x_n \in \mathbb{R}^r$, $\delta_0, \dots, \delta_n > 0$ be such that

$$\|x_i - x_j\| > \delta_i, \quad \delta_j \leq (1 + \epsilon)\delta_i$$

whenever $i < j \leq n$. Then

$$\#(\{i : i \leq n, \|x_i - x_n\| \leq \delta_i + \delta_n\}) \leq 5^r.$$

proof Set $I = \{i : i \leq n, \|x_i - x_n\| \leq \delta_n + \delta_i\}$.

(a) It will simplify the formulae of the main argument if we suppose for the time being that $\delta_n = 1$; in this case $1 \leq (1+\epsilon)\delta_i$, so that $\delta_i \geq \frac{1}{1+\epsilon}$ for every $i \leq n$, while we still have $\delta_i < \|x_i - x_n\|$ for every $i < n$, and $\|x_i - x_n\| \leq 1 + \delta_i$ for every $i \in I$.

For $i \in I$, define x_i' by saying that

– if $\|x_i - x_n\| \leq 2 + \epsilon$, $x_i' = x_i$;

– if $\|x_i - x_n\| > 2 + \epsilon$, x_i' is to be that point of the closed line segment from x_n to x_i which is at distance $2 + \epsilon$ from x_n.

(b) The point is that $\|x_i' - x_j'\| > 1 - \epsilon - \epsilon^2$ whenever i, j are distinct members of I. **P** We may suppose that $i < j$.

case 1 Suppose that $\|x_i - x_n\| \leq 2 + \epsilon$ and $\|x_j - x_n\| \leq 2 + \epsilon$. In this case

$$\|x_i' - x_j'\| = \|x_i - x_j\| \geq \delta_i \geq \frac{1}{1+\epsilon} \geq 1 - \epsilon.$$

case 2 Suppose that $\|x_i - x_n\| \geq 2 + \epsilon \geq \|x_j - x_n\|$. In this case

$$\begin{aligned}\|x_i' - x_j'\| = \|x_i' - x_j\| &\geq \|x_i - x_j\| - \|x_i - x_i'\| \\ &\geq \delta_i - \|x_i - x_n\| + 2 + \epsilon \geq \delta_i - \delta_i - 1 + 2 + \epsilon = 1 + \epsilon.\end{aligned}$$

case 3 Suppose that $\|x_i - x_n\| \leq 2 + \epsilon \leq \|x_j - x_n\|$. Then

$$\begin{aligned}\|x_i' - x_j'\| = \|x_i - x_j'\| &\geq \|x_i - x_j\| - \|x_j - x_j'\| > \delta_i - \|x_j - x_n\| + 2 + \epsilon \\ &\geq \delta_i - \delta_j - 1 + 2 + \epsilon \geq \delta_i - \delta_i(1+\epsilon) + 1 + \epsilon \geq 1 + \epsilon - \epsilon(2+\epsilon) \\ &\text{(because } \delta_i < \|x_i - x_n\| \leq 2 + \epsilon) \\ &= 1 - \epsilon - \epsilon^2.\end{aligned}$$

case 4 Suppose that $2 + \epsilon \leq \|x_j - x_n\| \leq \|x_i - x_n\|$. Let y be the point on the line segment between x_i and x_n which is the same distance from x_n as x_j. In this case

$$\|y - x_j\| \geq \|x_i - x_j\| - \|x_i - y\| \geq \delta_i - \|x_i - x_n\| + \|x_j - x_n\| \geq \|x_j - x_n\| - 1.$$

Because the triangles (x_n, y, x_j) and (x_n, x_i', x_j') are similar,

$$\|x_i' - x_j'\| = \tfrac{2+\epsilon}{\|x_j - x_n\|}\|y - x_j\| \geq (2+\epsilon)\tfrac{\|x_j - x_n\| - 1}{\|x_j - x_n\|} \geq 1 + \epsilon$$

because $\|x_j - x_n\| \geq 2 + \epsilon$.

case 5 Suppose that $2 + \epsilon \leq \|x_i - x_n\| \leq \|x_j - x_n\|$. This time, let y be the point on the line segment from x_n to x_j which is the same distance from x_n as x_i is. We now have

$$\begin{aligned}\|y - x_i\| &\geq \|x_i - x_j\| - \|x_j - y\| > \delta_i - \|x_j - x_n\| + \|x_i - x_n\| \\ &\geq \delta_j - \epsilon\delta_i - (\delta_j + 1) + \|x_i - x_n\| \\ &= \|x_i - x_n\| - 1 - \epsilon\delta_i \geq \|x_i - x_n\|(1 - \epsilon) - 1,\end{aligned}$$

so that

$$\begin{aligned}\|x_i' - x_j'\| = \tfrac{2+\epsilon}{\|x_i - x_n\|}\|y - x_i\| &> (2+\epsilon)\tfrac{\|x_i - x_n\|(1-\epsilon) - 1}{\|x_i - x_n\|} \\ &\geq (2+\epsilon)\tfrac{(2+\epsilon)(1-\epsilon) - 1}{2+\epsilon} = 1 - \epsilon - \epsilon^2.\end{aligned}$$

So we have the required inequality in all cases. **Q**

(c) Now consider the balls $B(x_i', \frac{1-\epsilon-\epsilon^2}{2})$ for $i \in I$. These are disjoint, all have Lebesgue measure $2^{-r}\beta_r(1-\epsilon-\epsilon^2)^r$ where β_r is the measure of the unit ball $B(\mathbf{0},1)$, and are all included in the ball $B(x_n, 2+\epsilon+\frac{1-\epsilon}{2})$, which has measure $2^{-r}\beta_r(5+\epsilon)^r$. So we must have

$$2^{-r}\beta_r(1-\epsilon-\epsilon^2)^r\#(I) \leq 2^{-r}\beta_r(5+\epsilon)^r.$$

But ϵ was declared to be so small that this implies that $\#(I) \leq 5^r$, as claimed.

(e) This proves the lemma in the case $\delta_n = 1$. For the general case, replace each x_i by $\delta_n^{-1}x_i$ and each δ_i by δ_i/δ_n; the change of scale does not affect the hypotheses or the set I.

472B Theorem Let $A \subseteq \mathbb{R}^r$ be a bounded set, and $\mathcal{I}$ a family of non-trivial closed balls in $\mathbb{R}^r$ such that every point of A is the centre of a member of $\mathcal{I}$. Then there is a family $\langle \mathcal{I}_k\rangle_{k<5^r}$ of countable subsets of $\mathcal{I}$ such that each $\mathcal{I}_k$ is disjoint and $\bigcup_{k<5^r}\mathcal{I}_k$ covers A.

proof (a) For each $x \in A$ let $\delta_x > 0$ be such that $B(x,\delta_x) \in \mathcal{I}$. If either A is empty or $\sup_{x\in A}\delta_x = \infty$, the result is trivial. (In the latter case, take $x \in A$ such that $\delta_x \geq \operatorname{diam} A$ and set $\mathcal{I}_0 = \{B(x,\delta_x)\}$, $\mathcal{I}_k = \emptyset$ for $k > 0$.) So let us suppose henceforth that $\{\delta_x : x \in A\}$ is bounded in $\mathbb{R}$. In this case, $C = \bigcup_{x\in A} B(x,\delta_x)$ is bounded in $\mathbb{R}^r$.

Fix $\epsilon > 0$ such that $(5^r+1)(1-\epsilon-\epsilon^2)^r > (5+\epsilon)^r$.

(b) Choose inductively a sequence $\langle B_n\rangle_{n\in\mathbb{N}}$ in $\mathcal{I}\cup\{\emptyset\}$ as follows. Given $\langle B_i\rangle_{i<n}$, then if $A \subseteq \bigcup_{i<n} B_i$ set $B_n = \emptyset$. Otherwise, set $\alpha_n = \sup\{\delta_x : x \in A\setminus\bigcup_{i<n}B_i\}$, choose $x_n \in A\setminus\bigcup_{i<n}B_i$ such that $(1+\epsilon)\delta_{x_n} \geq \alpha_n$, set $B_n = B(x_n,\delta_{x_n})$ and continue.

Now whenever $n \in \mathbb{N}$, $I_n = \{i : i < n,\ B_i \cap B_n \neq \emptyset\}$ has fewer than 5^r members. **P** We may suppose that $B_n \neq \emptyset$, in which case $B_i = B(x_i,\delta_{x_i})$ for every $i \leq n$, and the x_i, δ_{x_i} are such that, whenever $i < j \leq n$,

$$x_j \notin B_i, \text{ i.e., } \|x_i - x_j\| > \delta_{x_i},$$

$$\delta_{x_j} \leq \alpha_i \leq (1+\epsilon)\delta_{x_i}.$$

But now 472A gives the result at once. **Q**

(c) We may therefore define a function $f : \mathbb{N} \to \{0,1,\dots,5^r-1\}$ by setting

$$f(n) = \min\{k : 0 \leq k < 5^r,\ f(i) \neq k \text{ for every } i \in I_n\}$$

for every $n \in \mathbb{N}$. Set $\mathcal{I}_k = \{B_i : i \in \mathbb{N},\ f(i) = k,\ B_i \neq \emptyset\}$ for each $k < 5^r$. By the choice of f, $i \notin I_j$, so that $B_i \cap B_j = \emptyset$, whenever $i < j$ and $f(i) = f(j)$; thus every $\mathcal{I}_k$ is disjoint. Since $B_i \subseteq C$ for every i, $\sum\{\mu B_i : f(i) = k\} \leq \mu^* C$ for every $k < 5^r$, and $\sum_{i=0}^{\infty}\mu B_i \leq 5^r\mu^* C$ is finite.

(d) **?** Suppose, if possible, that

$$A \not\subseteq \bigcup_{k<5^r}\bigcup\mathcal{I}_k = \bigcup_{n\in\mathbb{N}} B_n.$$

Take $x \in A \setminus \bigcup_{n\in\mathbb{N}} B_n$. Then, first, $A \not\subseteq \bigcup_{i<n} B_i$ for every n, so that α_n is defined; next, $\alpha_n \geq \delta_x$, so that $(1+\epsilon)\delta_{x_n} \geq \delta_x$ for every n. But this means that $\mu B_n \geq \beta_r\big(\frac{\delta_x}{1+\epsilon}\big)^r$ for every n, and $\sum_{n=0}^{\infty}\mu B_n = \infty$; which is impossible. **X**

(e) Thus $A \subseteq \bigcup_{k<5^r}\bigcup\mathcal{I}_k$, as required.

472C Theorem Let λ be a Radon measure on $\mathbb{R}^r$, A a subset of $\mathbb{R}^r$ and $\mathcal{I}$ a family of non-trivial closed balls in $\mathbb{R}^r$ such that every point of A is the centre of arbitrarily small members of $\mathcal{I}$. Then

(a) there is a countable disjoint $\mathcal{I}_0 \subseteq \mathcal{I}$ such that $\lambda(A\setminus\bigcup\mathcal{I}_0) = 0$;

(b) for every $\epsilon > 0$ there is a countable $\mathcal{I}_1 \subseteq \mathcal{I}$ such that $A \subseteq \bigcup\mathcal{I}_1$ and $\sum_{B\in\mathcal{I}_1}\lambda B \leq \lambda^* A + \epsilon$.

proof (a)(i) The first step is to show that if $A' \subseteq A$ is bounded then there is a finite disjoint set $\mathcal{J} \subseteq \mathcal{I}$ such that $\lambda^*(A' \cap \bigcup\mathcal{J}) \geq 6^{-r}\lambda^* A'$. **P** If $\lambda^* A' = 0$ take $\mathcal{J} = \emptyset$. Otherwise, by 472B, there is a family $\langle\mathcal{J}_k\rangle_{k<5^r}$ of disjoint countable subsets of $\mathcal{I}$ such that $\bigcup_{k<5^r}\mathcal{J}_k$ covers A'. Accordingly

$$\lambda^* A' \leq \sum_{k=0}^{5^r-1}\lambda^*(A' \cap \bigcup\mathcal{J}_k)$$

and there is some $k < 5^r$ such that $\lambda^*(A' \cap \bigcup \mathcal{J}_k) \geq 5^{-r}\lambda^* A'$. Let $\langle B_i \rangle_{i\in\mathbb{N}}$ be a sequence running over $\mathcal{J}_k$; then

$$\lim_{n\to\infty} \lambda^*(A' \cap \bigcup_{i\leq n} B_i) = \lambda^*(A' \cap \bigcup \mathcal{J}_k) \geq 5^{-r}\lambda^* A',$$

so there is some $n \in \mathbb{N}$ such that $\lambda^*(A' \cap \bigcup_{i\leq n} B_i) \geq 6^{-r}\lambda^* A'$, and we can take $\mathcal{J} = \{B_i : i \leq n\}$. **Q**

(ii) Now choose $\langle \mathcal{K}_n \rangle_{n\in\mathbb{N}}$ inductively, as follows. Start by fixing on a sequence $\langle m_n \rangle_{n\in\mathbb{N}}$ in $\mathbb{N}$ such that every member of $\mathbb{N}$ appears infinitely often as an m_n. Take $\mathcal{K}_0 = \emptyset$. Given that $\mathcal{K}_n$ is a finite disjoint subset of $\mathcal{I}$, set $\mathcal{I}' = \{B : B \in \mathcal{I},\ B \cap \bigcup \mathcal{K}_n = \emptyset\}$, $A_n = A \cap B(\mathbf{0}, m_n) \setminus \bigcup \mathcal{K}_n$. Because every point of A is the centre of arbitrarily small members of $\mathcal{I}$, and $\bigcup \mathcal{K}_n$ is closed, every member of A_n is the centre of (arbitrarily small) members of $\mathcal{I}'$, and (i) tells us that there is a finite disjoint set $\mathcal{J}_n \subseteq \mathcal{I}'$ such that $\lambda^*(A_n \cap \bigcup \mathcal{J}_n) \geq 6^{-r}\lambda^* A_n$. Set $\mathcal{K}_{n+1} = \mathcal{K} \cup \mathcal{J}_n$, and continue. At the end of the induction, set $\mathcal{I}_0 = \bigcup_{n\in\mathbb{N}} \mathcal{K}_n$; because $\langle \mathcal{K}_n \rangle_{n\in\mathbb{N}}$ is non-decreasing and every $\mathcal{K}_n$ is disjoint, $\mathcal{I}_0$ is disjoint, and of course $\mathcal{I}_0 \subseteq \mathcal{I}$.

The effect of this construction is to ensure that

$$\lambda^*(A \cap B(\mathbf{0}, m_n) \setminus \bigcup \mathcal{K}_{n+1}) = \lambda^*(A_n \setminus \bigcup \mathcal{J}_n) = \lambda^* A_n - \lambda^*(A_n \cap \bigcup \mathcal{J}_n)$$

(because $\bigcup \mathcal{J}_n$ is a closed set, therefore measured by λ)

$$\begin{aligned} &\leq (1 - 6^{-r})\lambda^* A_n \\ &= (1 - 6^{-r})\lambda^*(A \cap B(\mathbf{0}, m_n) \setminus \bigcup \mathcal{K}_n) \end{aligned}$$

for every n. So, for any $m \in \mathbb{N}$,

$$\lambda^*(A \cap B(\mathbf{0}, m) \setminus \bigcup \mathcal{K}_n) \leq \lambda^*(A \cap B(\mathbf{0}, m))(1 - 6^{-r})^{\#(\{j : j<n, m_j = m\})} \to 0$$

as $n \to \infty$, and $\lambda^*(A \cap B(\mathbf{0}, m) \setminus \bigcup \mathcal{I}_0) = 0$. As m is arbitrary, $\lambda^*(A \setminus \bigcup \mathcal{I}_0) = 0$, as required.

(b)(i) Let $E \supseteq A$ be such that $\lambda E = \lambda^* A$, and $H \supseteq E$ an open set such that $\lambda H \leq \lambda E + \frac{1}{2}\epsilon$ (256Bb). Set $\mathcal{I}' = \{B : B \in \mathcal{I},\ B \subseteq H\}$. Then every point of A is the centre of arbitrarily small members of $\mathcal{I}'$, so by (a) there is a disjoint family $\mathcal{I}_0 \subseteq \mathcal{I}'$ such that $\lambda(A \setminus \bigcup \mathcal{I}_0) = 0$. Of course

$$\sum_{B\in\mathcal{I}_0} \lambda B = \lambda(\bigcup \mathcal{I}_0) \leq \lambda H \leq \lambda^* A + \tfrac{1}{2}\epsilon.$$

(ii) For $m \in \mathbb{N}$ set $A_m = A \cap B(\mathbf{0}, m) \setminus \bigcup \mathcal{I}_0$. Then there is a $\mathcal{J}_m \subseteq \mathcal{I}$, covering A_m, such that $\sum_{B\in\mathcal{J}_m} \lambda B \leq 2^{-m-2}\epsilon$. **P** There is an open set $G \supseteq A_m$ such that $\lambda G \leq 5^{-r}2^{-m-2}\epsilon$. Now $\mathcal{I}'' = \{B : B \in \mathcal{I},\ B \subseteq G\}$ covers A_m, so there is a family $\langle \mathcal{J}_{mk} \rangle_{k<5^r}$ of disjoint countable subfamilies of $\mathcal{I}''$ such that $\mathcal{J}_m = \bigcup_{k<5^r} \mathcal{J}_{mk}$ covers A_m. For each k,

$$\sum_{B\in\mathcal{J}_{mk}} \lambda B = \lambda(\bigcup \mathcal{J}_{mk}) \leq \lambda G,$$

so

$$\sum_{B\in\mathcal{J}_m} \lambda B \leq 5^r \lambda G \leq 2^{-m-2}\epsilon.$$ **Q**

(iii) Setting $\mathcal{I}_1 = \mathcal{I}_0 \cup \bigcup_{m\in\mathbb{N}} \mathcal{J}_m$ we have a cover of A by members of $\mathcal{I}$, and

$$\begin{aligned} \sum_{B\in\mathcal{I}_1} \lambda B &\leq \sum_{B\in\mathcal{I}_0} \lambda B + \sum_{m=0}^{\infty} \sum_{B\in\mathcal{J}_m} \lambda B \\ &\leq \lambda^* A + \frac{1}{2}\epsilon + \sum_{m=0}^{\infty} 2^{-m-2}\epsilon = \lambda^* A + \epsilon. \end{aligned}$$

472D Besicovitch's Density Theorem Let λ be any Radon measure on $\mathbb{R}^r$. Then, for any locally λ-integrable real-valued function f,

(a) $f(y) = \lim_{\delta\downarrow 0} \frac{1}{\lambda B(y,\delta)} \int_{B(y,\delta)} f d\lambda$,

(b) $\lim_{\delta\downarrow 0} \frac{1}{\lambda B(y,\delta)} \int_{B(y,\delta)} |f(x) - f(y)| \lambda(dx) = 0$

for λ-almost every $y \in \mathbb{R}^r$.

Remark The theorem asserts that, for λ-almost every y, limits of the form $\lim_{\delta\downarrow 0} \frac{1}{\lambda B(y,\delta)} \dots$ are defined; in my usage, this includes the assertion that $\lambda B(y,\delta) > 0$ for all sufficiently small $\delta > 0$.

proof (Compare 261C and 261E.)

(a) Let Z be the support of λ (411Nd); then Z is λ-conegligible and $\lambda B(y,\delta) > 0$ whenever $y \in Z$ and $\delta > 0$. For $q < q'$ in $\mathbb{Q}$, $n \in \mathbb{N}$ set

$$A_{nqq'} = \{y : y \in Z \cap \operatorname{dom} f,\ \|y\| \le n,\ f(y) \le q,\ \limsup_{\delta\downarrow 0} \frac{1}{\lambda B(y,\delta)} \int_{B(y,\delta)} f d\lambda > q'\}.$$

Then $\lambda A_{nqq'} = 0$. **P** Let $\epsilon > 0$. Then there is an $\eta \in]0,\epsilon]$ such that $\int_F |f| d\lambda \le \epsilon$ whenever $F \subseteq B(\mathbf{0},n)$ and $\lambda F \le \eta$ (225A). Let E be a measurable envelope of $A_{nqq'}$ included in $\{y : y \in Z \cap \operatorname{dom} f,\ f(y) \le q\}$, and take an open set $G \supseteq E$ such that $\lambda(G \setminus E) \le \eta$ (256Bb). Let $\mathcal{I}$ be the family of non-singleton closed balls $B \subseteq G$ such that $\int_B f \ge q'\lambda B$. Then every point of $A_{nqq'}$ belongs to arbitrarily small members of $\mathcal{I}$, so there is a disjoint family $\mathcal{I}_0 \subseteq \mathcal{I}$ such that $\lambda(A_{nqq'} \setminus \bigcup \mathcal{I}_0) = 0$ (472C). Now $\lambda(E \setminus \bigcup \mathcal{I}_0) = 0$ and $\lambda((\bigcup \mathcal{I}_0) \setminus E) \le \eta \le \epsilon$, so

$$\begin{aligned} q'\lambda E &\le q'\lambda(\textstyle\bigcup \mathcal{I}_0) + \epsilon|q'| = \sum_{B\in\mathcal{I}_0} q'\lambda B + \epsilon|q'| \\ &\le \sum_{B\in\mathcal{I}_0} \int_B f d\lambda + \epsilon|q'| = \int_{\bigcup\mathcal{I}_0} f d\lambda + \epsilon|q'| \\ &\le \int_E f d\lambda + \epsilon(1+|q'|) \le q\lambda E + \epsilon(1+|q'|), \end{aligned}$$

and

$$(q'-q)\lambda^* A_{nqq'} = (q'-q)\lambda E \le (1+|q'|)\epsilon.$$

As ϵ is arbitrary, $\lambda^* A_{nqq'} = 0$. **Q**

As n, q and q' are arbitrary,

$$\limsup_{\delta\downarrow 0} \frac{1}{\lambda B(y,\delta)} \int_{B(y,\delta)} f \le f(y)$$

for λ-almost every $y \in Z$, therefore for λ-almost every $y \in \mathbb{R}^r$. Similarly, or applying the same argument to $-f$,

$$\liminf_{\delta\downarrow 0} \frac{1}{\lambda B(y,\delta)} \int_{B(y,\delta)} f \ge f(y)$$

for λ-almost every y, and

$$\lim_{\delta\downarrow 0} \frac{1}{\lambda B(y,\delta)} \int_{B(y,\delta)} f \text{ exists} = f(y)$$

for λ-almost every y.

(b) Now, for each $q \in \mathbb{Q}$ set $g_q(x) = |f(x) - q|$ for $x \in \operatorname{dom} f$. By (a), we have a λ-conegligible set D such that

$$\lim_{\delta\downarrow 0} \frac{1}{\lambda B(y,\delta)} \int_{B(y,\delta)} g_q d\lambda = g_q(y)$$

for every $y \in D$ and $q \in \mathbb{Q}$. Now, if $y \in D$ and $\epsilon > 0$, there is a $q \in \mathbb{Q}$ such that $|f(y) - q| \le \epsilon$, and a $\delta_0 > 0$ such that

$$|\frac{1}{\lambda B(y,\delta)} \int_{B(y,\delta)} g_q d\lambda - g_q(y)| \le \epsilon$$

whenever $0 < \delta \le \delta_0$. But in this case

$$\begin{aligned}\frac{1}{\lambda B(y,\delta)}&\int_{B(y,\delta)}|f(x)-f(y)|\lambda(dx)\\ &\leq \frac{1}{\lambda B(y,\delta)}\int_{B(y,\delta)}|f(x)-q|\lambda(dx)+\frac{1}{\lambda B(y,\delta)}\int_{B(y,\delta)}|q-f(y)|\lambda(dx)\\ &\leq 2\epsilon.\end{aligned}$$

As ϵ is arbitrary,

$$\lim_{\delta\downarrow 0}\frac{1}{\lambda B(y,\delta)}\int_{B(y,\delta)}|f(x)-f(y)|\lambda(dx)=0;$$

as this is true for every $y\in D$, the theorem is proved.

***472E Proposition** Let λ, λ' be Radon measures on $\mathbb{R}^r$, and $G\subseteq\mathbb{R}^r$ an open set. Let Z be the support of λ, and for $x\in Z\cap G$ set

$$M(x)=\sup\{\frac{\lambda' B}{\lambda B}: B\subseteq G \text{ is a non-trivial ball with centre } x\}.$$

Then

$$\lambda\{x: x\in Z,\, M(x)\geq t\}\leq\frac{5^r}{t}\lambda' G$$

for every $t>0$.

proof The function $M: Z\to[0,\infty]$ is lower semi-continuous. **P** If $M(x)>t\geq 0$, there is a $\delta>0$ such that $B(x,\delta)\subseteq G$ and $\lambda' B(x,\delta)>t\lambda B(x,\delta)$. Because λ is a Radon measure, there is an open set $V\supseteq B(x,\delta)$ such that $V\subseteq G$ and $\lambda' B(x,\delta)>t\lambda V$; because $B(x,\delta)$ is compact, there is an $\eta>0$ such that $B(x,\delta+2\eta)\subseteq V$. Now if $y\in Z$ and $\|y-x\|\leq\eta$,

$$B(x,\delta)\subseteq B(y,\delta+\eta)\subseteq V,$$

so $\lambda' B(y,\delta+\eta)>t\lambda B(y,\delta+\eta)$ and $M(y)>t$. **Q**

In particular, $H_t=\{x: x\in Z\cap G,\, M(x)>t\}$ is always measured by λ. Now, given $t>0$, let $\mathcal{I}$ be the set of non-trivial closed balls $B\subseteq G$ such that $\lambda' B>t\lambda B$. By 472B, there is a family $\langle\mathcal{I}_k\rangle_{k<5^r}$ of countable disjoint subsets of $\mathcal{I}$ such that $\bigcup_{k<5^r}\mathcal{I}_k$ covers H_t. So

$$\lambda H_t\leq\sum_{k=0}^{5^r-1}\sum_{B\in\mathcal{I}_k}\lambda B\leq\frac{1}{t}\sum_{k=0}^{5^r-1}\sum_{B\in\mathcal{I}_k}\lambda' B\leq\frac{5^r}{t}\lambda' G,$$

as claimed.

***472F Theorem** Let λ be a Radon measure on $\mathbb{R}^r$, and $f\in\mathcal{L}^p(\lambda)$ any function, where $1<p<\infty$. Let Z be the support of λ, and for $x\in Z$ set $f^*(x)=\sup_{\delta>0}\frac{1}{\lambda B(x,\delta)}\int_{B(x,\delta)}|f|d\lambda$. Then f^* is lower semi-continuous, and $\|f^*\|_p\leq 2\big(\frac{5^r p}{p-1}\big)^{1/p}\|f\|_p$.

proof (a) Replacing f by $|f|$ if necessary, we may suppose that $f\geq 0$. Z is λ-conegligible, so that f^* is defined λ-almost everywhere. Next, f^* is lower semi-continuous. **P** I repeat an idea from the proof of 472E. If $f^*(x)>t\geq 0$, there is a $\delta>0$ such that $\int_{B(x,\delta)}|f|d\lambda>t\lambda B(x,\delta)$. Because λ is a Radon measure, there is an open set $V\supseteq B(x,\delta)$ such that $\int_{B(x,\delta)}|f|d\lambda>t\lambda V$; because $B(x,\delta)$ is compact, there is an $\eta>0$ such that $B(x,\delta+2\eta)\subseteq V$; and now $f^*(y)>t$ for every $y\in Z\cap B(x,\eta)$. **Q**

(b) For $t>0$, set $H_t=\{x: x\in Z,\, f^*(x)>t\}$, $F_t=\{x: x\in\operatorname{dom} f,\, f(x)\geq t\}$. Then

$$\lambda H_t\leq\frac{2\cdot 5^r}{t}\int_{F_{t/2}}f d\lambda$$

for every $t>0$. **P** Set $g=f\times\chi F_{t/2}$. Because $(\frac{t}{2})^p\lambda F_{t/2}\leq\|f\|_p^p$ is finite, $\lambda F_{t/2}$ is finite, $\chi F_{t/2}\in\mathcal{L}^q(\lambda)$ (where $\frac{1}{p}+\frac{1}{q}=1$) and $g\in\mathcal{L}^1(\lambda)$ (244E). Let λ' be the indefinite-integral measure defined by g over λ (§234); then λ' is totally finite, and is a Radon measure (416S). Set

$$M(x) = \sup\{\frac{\lambda' B}{\lambda B} : B \subseteq \mathbb{R}^r \text{ is a non-trivial ball with centre } x\}$$

for $x \in Z$. Then $f^*(x) \leq M(x) + \frac{t}{2}$ for every $x \in Z$, just because

$$\int_B f d\lambda \leq \frac{t}{2}\lambda B + \int_B g\, d\lambda = \frac{t}{2}\lambda B + \lambda' B$$

for every closed ball B. Accordingly

$$\lambda H_t \leq \lambda\{x : M(x) > \frac{t}{2}\} \leq \frac{2\cdot 5^r}{t}\lambda' \mathbb{R}^r = \frac{2\cdot 5^r}{t}\int_{F_{t/2}} f d\lambda. \; \blacksquare$$

(c) As in part (c) of the proof of 286A, we now have

$$\begin{aligned}\int (f^*)^p d\lambda &= \int_0^\infty \lambda\{x : f^*(x)^p > t\}dt = p\int_0^\infty t^{p-1}\lambda\{x : f^*(x) > t\}dt \\ &\leq 2\cdot 5^r p \int_0^\infty t^{p-2}\int_{F_{t/2}} f d\lambda dt = 2\cdot 5^r p \int_{\mathbb{R}^r} f(x)\int_0^{2f(x)} t^{p-2} dt\lambda(dx) \\ &= 2\cdot 5^r p \int_{\mathbb{R}^r} \frac{2^{p-1}}{p-1} f(x)^p \lambda(dx) = \frac{2^p 5^r p}{p-1}\int f^p d\lambda.\end{aligned}$$

Taking pth roots, we have the result.

472X Basic exercises (a) Show that if λ, λ' are Radon measures on $\mathbb{R}^r$ which agree on closed balls, they are equal.

(b) Let λ be a Radon measure on $\mathbb{R}^r$. Let $A \subseteq \mathbb{R}^r$ be a non-empty set, and $\epsilon > 0$. Show that there is a sequence $\langle B_n\rangle_{n\in\mathbb{N}}$ of closed balls in $\mathbb{R}^r$, all of radius at most ϵ and with centres in A, such that $A \subseteq \bigcup_{n\in\mathbb{N}} B_n$ and $\sum_{n=0}^\infty \lambda B_n \leq \lambda^* A + \epsilon$.

(c) Let λ be a non-zero Radon measure on $\mathbb{R}^r$ and F its support. Show that we have a lower density ϕ (definition: 341C) for the subspace measure λ_F defined by setting $\phi E = \{x : x \in F, \lim_{\delta\downarrow 0}\frac{\lambda(E\cap B(x,\delta))}{\lambda B(x,\delta)} = 1\}$ whenever λ_F measures E.

472Y Further exercises (a) (i) Let $\mathcal{I}$ be a finite family of intervals (open, closed or half-open) in $\mathbb{R}$. Show that there are subfamilies $\mathcal{I}_0$, $\mathcal{I}_1 \subseteq \mathcal{I}$, both disjoint, such that $\mathcal{I}_0 \cup \mathcal{I}_1$ covers $\bigcup\mathcal{I}$. (*Hint*: induce on $\#(\mathcal{I})$.) Show that this remains true if any totally ordered set is put in place of $\mathbb{R}$. (ii) Show that if $\mathcal{I}$ is any family of non-trivial intervals in $\mathbb{R}$ such that none contains the centre of any other, then $\mathcal{I}$ is expressible as $\mathcal{I}_0 \cup \mathcal{I}_1$ where both $\mathcal{I}_0$ and $\mathcal{I}_1$ are disjoint.

(b) Let $m = m(r)$ be the largest number such that there are $u_1, \ldots, u_m \in \mathbb{R}^r$ such that $\|u_i\| = 1$ for every i, $\|u_i - u_j\| \geq 1$ for all $i \neq j$. Let $A \subseteq \mathbb{R}^r$ be a bounded set and $x \mapsto \delta_x : A \to]0,\infty[$ a bounded function; set $B_x = B(x,\delta_x)$ for $x \in A$. (i) Show that $m < 3^r$. (ii) Show that there is an $\epsilon \in \left]0, \frac{1}{10}\right]$ such that whenever $\|u_0\| = \ldots = \|u_m\| = 1$ there are distinct i, $j \leq m$ such that $u_i \cdot u_j > \frac{1}{2}(1+\epsilon)$. (iii) Suppose that u, $v \in \mathbb{R}^r$ are such that $\frac{1}{3} \leq \|u\| \leq 1$, $\|v\| \leq 1+\epsilon$ and $\|u - v\| > 1$. Show that the angle $u\widehat{\mathbf{0}}v$ has cosine at most $\frac{1}{2}(1+\epsilon)$. (*Hint*: maximise $\frac{a^2+b^2-c^2}{2ab}$ subject to $\frac{1}{3} \leq a \leq 1$, $b \leq 1+\epsilon$ and $c \geq 1$.) (iv) Suppose that $\langle x_n\rangle_{n\in\mathbb{N}}$ is a sequence in A such that $x_n \notin B_{x_i}$ for $i < n$ and $(1+\epsilon)\delta_{x_n} \geq \sup\{\delta_x : x \in A \setminus \bigcup_{i<n} B_{x_i}\}$ for every n. Show that $A \subseteq \bigcup_{n\in\mathbb{N}} B_{x_n}$. (v) Take $y \in \mathbb{R}^r$. Show that there is at most one n such that $\|y - x_n\| \leq \frac{1}{3}\delta_{x_n}$. (vi) Show that if $i < j$ and $\frac{1}{3}\delta_{x_i} \leq \|y - x_i\| \leq \delta_{x_i}$, $\|y - x_j\| \leq \delta_j$ then the cosine of the angle $x_i\widehat{y}x_j$ is at most $\frac{1}{2}(1+\epsilon)$. (vii) Show that $\#(\{i : y \in B_{x_i}\}) \leq m+1$.

Hence show that if $\mathcal{I}$ is any family of non-trivial closed balls such that every point of A is the centre of some member of $\mathcal{I}$, then there is a countable $\mathcal{I}_0 \subseteq \mathcal{I}$, covering A, such that no point of $\mathbb{R}^r$ belongs to more than 3^r members of $\mathcal{I}_0$.

(c) Use 472Yb to prove an alternative version of 472B, but with the constant 9^r in place of 5^r.

(d) Let λ be a Radon measure on $\mathbb{R}^r$, and f a λ-integrable real-valued function. Show that $f^*(x) = \sup_{\delta>0} \frac{1}{\lambda B(x,\delta)} \int_{B(x,\delta)} |f| d\lambda$ is defined and finite for λ-almost every $x \in \mathbb{R}^r$.

(e) Let λ, λ' be Radon measures on $\mathbb{R}^r$. (i) Show that $g(x) = \lim_{\delta \downarrow 0} \frac{\lambda' B_r(x)}{\lambda B_r(x)}$ is defined in $\mathbb{R}$ for λ-almost every x. (ii) Setting $\lambda_0 = \sup_{n\in\mathbb{N}} \lambda' \wedge n\lambda$ in the cone of Radon measures on $\mathbb{R}^r$ (437Yj), show that g is a Radon-Nikodým derivative of λ_0 with respect to λ. (*Hint*: show that if λ and λ' are mutually singular then $g = 0$ λ-a.e.)

472 Notes and comments I gave primacy to the 'weak' Vitali's theorem in 261B because I think it is easier than the 'strong' form in 472C, it uses the same ideas as the original one-dimensional theorem in 221A, and it is adequate for the needs of Volume 2. Any proper study of general measures on $\mathbb{R}^r$, however, will depend on the ideas in 472A-472C. You will see that in 472B, as in other forms of Vitali's theorem, there is a key step in which a sequence is chosen greedily. This time we must look much more carefully at the geometry of $\mathbb{R}^r$ because we can no longer rely on a measure to tell us what is happening. (Though you will observe that I still use the elementary properties of Euclidean volume in the argument of 472A.) Once we have reached 472C, however, we are in a position to repeat all the arguments of 261C-261E in much greater generality (472D), and, as a bonus, can refine 261F (472Xb). For more in this direction see Mattila 95 and Federer 69, §2.8.

It is natural to ask whether the constant '5^r' in 472A is best possible. The argument of 472A is derived from Sullivan 94, where a more thorough analysis is given. It seems that even for $r = 2$ the best constant is unknown. (For $r = 1$, the best constant is 2; see 472Ya.) Note that even for finite families $\mathcal{I}$ we should have to find the colouring number of a graph (counting two balls as linked if they intersect), so it may well be a truly difficult problem. The method in 472B amounts to using the greedy colouring algorithm after ordering the balls by size, and one does not expect such approaches to give exact colouring numbers. Of course the questions addressed here depend only on the existence of *some* function of r to do the job.

An alternative argument runs through a kind of pointwise version of 472A (472Yb-472Yc). It gives a worse constant but is attractive in other ways. For many of the applications of 472C, the result of 472Yb is already sufficient.

The constant $2\big(\frac{5^r p}{p-1}\big)^{1/p}$ in 472F makes no pretence to be 'best', or even 'good'. The only reason for giving a formula at all is to emphasize the remarkable fact that it does not depend on the measure λ. The theorems of this section are based on the metric geometry of Euclidean space, not on any special properties of Lebesgue measure. The constants *do* depend on the dimension, so that even in Hilbert space (for instance) we cannot expect any corresponding results.

473 Poincaré's inequality

In this section I embark on the main work of the chapter, leading up to the Divergence Theorem in §475. I follow the method in Evans & Gariepy 92. The first step is to add some minor results on differentiable and Lipschitz functions to those already set out in §262 (473B-473C). Then we need to know something about convolution products (473D), extending ideas in §§256 and 444; in particular, it will be convenient to have a fixed sequence $\langle \tilde{h}_n \rangle_{n\in\mathbb{N}}$ of smoothing functions with some useful special properties (473E).

The new ideas of the section begin with the Gagliardo-Nirenberg-Sobolev inequality, relating $\|f\|_{r/(r-1)}$ to $\|\operatorname{grad} f\|_1$. In its simplest form (473H) it applies only to functions with compact support; we need to work much harder to get results which we can use to estimate $\int_B |f|^{r/(r-1)}$ in terms of $\int_B \|\operatorname{grad} f\|$ and $\int_B f$ for balls B (473I, 473K).

473A Notation For the next three sections, $r \geq 2$ will be a fixed integer. For $x \in \mathbb{R}^r$ and $\delta \geq 0$, $B(x,\delta) = \{y : \|y - x\| \leq \delta\}$ will be the closed ball with centre x and radius δ. I will write $\partial B(x,\delta)$ for the

boundary of $B(x,\delta)$, the sphere $\{y : \|y-x\| = \delta\}$. $S_{r-1} = \partial B(\mathbf{0},1)$ will be the unit sphere. As in Chapter 26, I will use Greek letters to represent coordinates of vectors, so that $x = (\xi_1, \dots, \xi_r)$, etc.

μ will always be Lebesgue measure on $\mathbb{R}^r$. $\beta_r = \mu B(\mathbf{0},1)$ will be the r-dimensional volume of the unit ball, that is,

$$\begin{aligned}\beta_r &= \frac{\pi^k}{k!} \text{ if } r = 2k \text{ is even,}\\ &= \frac{2^{2k+1}k!\pi^k}{(2k+1)!} \text{ if } r = 2k+1 \text{ is odd}\end{aligned}$$

(252Q). ν will be normalized Hausdorff $r-1$-dimensional measure on $\mathbb{R}^r$, that is, $\nu = 2^{-r+1}\beta_{r-1}\mu_{H,r-1}$, where $\mu_{H,r-1}$ is $r-1$-dimensional Hausdorff measure on $\mathbb{R}^r$ as described in §264, and

$$\begin{aligned}\beta_{r-1} &= \frac{2^{2k}k!\pi^{k-1}}{(2k)!} \text{ if } r = 2k \text{ is even,}\\ &= \frac{\pi^k}{k!} \text{ if } r = 2k+1 \text{ is odd}\end{aligned}$$

is the Lebesgue measure of a ball of diameter 1 in $\mathbb{R}^{r-1}$ (264I). Recall from 265F and 265H that $\nu S_{r-1} = 2\pi\beta_{r-2} = r\beta_r$ (counting β_0 as 1).

473B Differentiable functions (a) Recall from §262 that a function ϕ from a subset of $\mathbb{R}^r$ to $\mathbb{R}^s$ (where $s \geq 1$) is differentiable at $x \in \mathbb{R}^r$, with derivative an $s \times r$ matrix T, if for every $\epsilon > 0$ there is a $\delta > 0$ such that $\|\phi(y) - \phi(x) - T(y-x)\| \leq \epsilon\|y-x\|$ whenever $\|y-x\| \leq \delta$; this includes the assertion that $B(x,\delta) \subseteq \operatorname{dom}\phi$. In this case, the coefficients of T are the partial derivatives $\frac{\partial\phi_j}{\partial\xi_i}(x)$ at x, where $\phi_1, \dots, \phi_s$ are the coordinate functions of ϕ, and $\frac{\partial}{\partial\xi_i}$ represents partial differentiation with respect to the ith coordinate (262Ic).

(b) When $s = 1$, so that we have a real-valued function f defined on a subset of $\mathbb{R}^r$, I will write $(\operatorname{grad} f)(x)$ for the derivative of f at x, the **gradient** of f. If we strictly adhere to the language of (a), $\operatorname{grad} f$ is a $1 \times r$ matrix $\begin{pmatrix}\frac{\partial f}{\partial\xi_1} & \dots & \frac{\partial f}{\partial\xi_r}\end{pmatrix}$; but it is convenient to treat it as a vector, so that $\operatorname{grad} f(x)$ (when defined) belongs to $\mathbb{R}^r$, and we can speak of $y \cdot \operatorname{grad} f(x)$ rather than $(\operatorname{grad} f(x))(y)$, etc.

(c) Chain rule for functions of many variables I find that I have not written out the following basic fact. Let $\phi : A \to \mathbb{R}^s$ and $\psi : B \to \mathbb{R}^p$ be functions, where $A \subseteq \mathbb{R}^r$ and $B \subseteq \mathbb{R}^s$. If $x \in A$ is such that ϕ is differentiable at x, with derivative S, and ψ is differentiable at $\phi(x)$, with derivative T, then the composition $\psi\phi$ is differentiable at x, with derivative TS.

P Recall that if we regard S and T as linear operators, they have finite norms (262H). Given $\epsilon > 0$, let $\eta > 0$ be such that $\eta\|T\| + \eta(\|S\| + \eta) \leq \epsilon$. Let $\delta_1, \delta_2 > 0$ be such that $\phi(y)$ is defined and $\|\phi(y) - \phi(x) - S(y-x)\| \leq \eta\|y-x\|$ whenever $\|y-x\| \leq \delta_1$, and $\psi(z)$ is defined and $\|\psi(z) - \psi\phi(x) - T(z-\phi(x))\| \leq \eta\|z-\phi(x)\|$ whenever $\|z-\phi(x)\| \leq \delta_2$. Set $\delta = \min(\delta_1, \frac{\delta_2}{\eta+\|S\|}) > 0$. If $\|y-x\| \leq \delta$, then $\phi(y)$ is defined and

$$\|\phi(y) - \phi(x)\| \leq \|S(y-x)\| + \|\phi(y) - \phi(x) - S(y-x)\| \leq (\|S\| + \eta)\|y-x\| \leq \delta_2,$$

so $\psi\phi(y)$ is defined and

$$\begin{aligned}&\|\psi\phi(y) - \psi\phi(x) - TS(y-x)\|\\ &\quad\leq \|\psi\phi(y) - \psi\phi(x) - T(\phi(y) - \phi(x))\| + \|T\|\|\phi(y) - \phi(x) - S(y-x)\|\\ &\quad\leq \eta\|\phi(y) - \phi(x) - S(y-x)\| + \|T\|\eta\|y-x\|\\ &\quad\leq \eta(\|S\| + \eta)\|y-x\| + \|T\|\eta\|y-x\| \leq \epsilon\|y-x\|;\end{aligned}$$

as ϵ is arbitrary, $\psi\phi$ is differentiable at x with derivative TS. **Q**

(d) It follows that if f and g are real-valued functions defined on a subset of $\mathbb{R}^r$, and $x \in \operatorname{dom} f \cap \operatorname{dom} g$ is such that $(\operatorname{grad} f)(x)$ and $(\operatorname{grad} g)(x)$ are both defined, then $\operatorname{grad}(f \times g)(x)$ is defined and equal to $f(x)\operatorname{grad} g(x) + g(x)\operatorname{grad} f(x)$. **P** Set $\phi(y) = \begin{pmatrix} f(y) \\ g(y) \end{pmatrix}$ for $y \in \operatorname{dom} f \cap \operatorname{dom} g$; then ϕ is differentiable at x with derivative the $2 \times r$ matrix $\begin{pmatrix} \operatorname{grad} f(x) \\ \operatorname{grad} g(x) \end{pmatrix}$ (262Ib). Set $\psi(z) = \zeta_1\zeta_2$ for $z = (\zeta_1, \zeta_2) \in \mathbb{R}^2$; then ψ is differentiable everywhere, with derivative the 1×2 matrix $(\,\zeta_2 \quad \zeta_1\,)$. So $f \times g = \psi\phi$ is differentiable at x with derivative

$$(\,g(x) \quad f(x)\,)\begin{pmatrix} \operatorname{grad} f(x) \\ \operatorname{grad} g(x) \end{pmatrix} = g(x)\operatorname{grad} f(x) + f(x)\operatorname{grad} g(x). \quad \textbf{Q}$$

(e) Let D be a subset of $\mathbb{R}^r$ and $\phi : D \to \mathbb{R}^s$ any function. Set $D_0 = \{x : x \in D, \phi \text{ is differentiable at } x\}$. Then the derivative of ϕ, regarded as a function from D_0 to $\mathbb{R}^{rs}$, is (Lebesgue) measurable. **P** Use 262P; the point is that, writing $T(x)$ for the derivative of ϕ at x, $T(x)$ is surely a derivative of $\phi\restriction D_0$, relative to D_0, at every point of D_0. **Q** (See also 473Ya.)

(f) A function $\phi : \mathbb{R}^r \to \mathbb{R}^s$ is **smooth** if it is differentiable arbitrarily often; that is, if all its repeated partial derivatives

$$\frac{\partial^m \phi_j}{\partial\xi_{i_1}\ldots\partial\xi_{i_m}}$$

are defined and continuous everywhere on $\mathbb{R}^r$. I will write $\mathcal{D}$ for the family of real-valued functions on $\mathbb{R}^r$ which are smooth and have compact support.

473C Lipschitz functions (a) If f and g are bounded real-valued Lipschitz functions, defined on any subsets of $\mathbb{R}^r$, then $f \times g$, defined on $\operatorname{dom} f \cap \operatorname{dom} g$, is Lipschitz. **P** Let γ_f, M_f, γ_g and M_g be such that $|f(x)| \le M_f$ and $|f(x)-f(y)| \le \gamma_f\|x-y\|$ for all $x, y \in \operatorname{dom} f$, while $|g(x)| \le M_g$ and $|g(x)-g(y)| \le \gamma_g\|x-y\|$ for all $x, y \in \operatorname{dom} g$. Then for any $x, y \in \operatorname{dom} f \cap \operatorname{dom} g$,

$$\begin{aligned} |f(x)g(x) - f(y)g(y)| &\le |f(x)||g(x) - g(y)| + |g(y)||f(x) - f(y)| \\ &\le (M_f\gamma_g + M_g\gamma_f)\|x - y\|. \end{aligned}$$

So $M_f\gamma_g + M_g\gamma_f$ is a Lipschitz constant for $f \times g$. **Q**

(b) Suppose that F_1, $F_2 \subseteq \mathbb{R}^r$ are closed sets with convex union C. Let $f : C \to \mathbb{R}$ be a function such that $f\restriction F_1$ and $f\restriction F_2$ are both Lipschitz. Then f is Lipschitz. **P** For each j, let γ_j be a Lipschitz constant for $f\restriction F_j$, and set $\gamma = \max(\gamma_1, \gamma_2)$, so that γ is a Lipschitz constant for both $f\restriction F_1$ and $f\restriction F_2$. Take any x, $y \in C$. If both belong to the same F_j, then $|f(x) - f(y)| \le \gamma\|x - y\|$. If $x \in F_j$ and $y \notin F_j$, then y must belong to F_{3-j}, and $(1-t)x + ty \in F_1 \cup F_2$ for every $t \in [0,1]$, because C is convex. Set $t_0 = \sup\{t : t \in [0,1], (1-t)x + ty \in F_j\}$, $z = (1-t_0)x + t_0y$; then $z \in F_1 \cap F_2$, because both are closed, so

$$|f(x) - f(y)| \le |f(x) - f(z)| + |f(z) - f(y)| \le \gamma\|x - z\| + \gamma\|z - y\| = \gamma\|x - y\|.$$

As x and y are arbitrary, γ is a Lipschitz constant for f. **Q**

(c) Suppose that $f : \mathbb{R}^r \to \mathbb{R}$ is Lipschitz. Recall that by Rademacher's theorem (262Q), $\operatorname{grad} f$ is defined almost everywhere. All the partial derivatives of f are (Lebesgue) measurable, by 473Be, so $\operatorname{grad} f$ is (Lebesgue) measurable on its domain. If γ is a Lipschitz constant for f, $\|\operatorname{grad} f(x)\| \le \gamma$ whenever $\operatorname{grad} f(x)$ is defined. **P** If $z \in \mathbb{R}^r$, then

$$\lim_{t\downarrow 0} \frac{1}{t}|f(x + tz) - f(x) - tz\,.\operatorname{grad} f(x)| = 0,$$

so

$$|z\,.\operatorname{grad} f(x)| = \lim_{t\downarrow 0} \frac{1}{t}|f(x + tz) - f(x)| \le \gamma\|z\|;$$

as z is arbitrary, $\|\operatorname{grad} f(x)\| \le \gamma$. **Q**

(d) Conversely, if $f : \mathbb{R}^r \to \mathbb{R}$ is differentiable and $\|\operatorname{grad} f(x)\| \leq \gamma$ for every x, then γ is a Lipschitz constant for f. **P** Take $x, y \in \mathbb{R}^r$. Set $g(t) = f((1-t)x+ty)$ for $t \in \mathbb{R}$. The function $t \mapsto (1-t)x+ty : \mathbb{R} \to \mathbb{R}^r$ is everywhere differentiable, with constant derivative $y - x$, so by 473Bc g is differentiable, with derivative $g'(t) = y - x \cdot gradf(g(t))$ for every t; in particular, $|g'(t)| \leq \gamma\|y - x\|$ for every t. Now, by the Mean Value Theorem, there is a $t \in [0, 1]$ such that $g(1) - g(0) = g'(t)$, so that $|f(y) - f(x)| = |g'(t)| \leq \gamma\|y - x\|$. As x and y are arbitrary, f is γ-Lipschitz. **Q**

(e) Note that if $f \in \mathcal{D}$ then all its partial derivatives are continuous functions with compact support, so are bounded (436Ia), and f is Lipschitz as well as bounded, by (d) here.

(f)(i) If $D \subseteq \mathbb{R}^r$ is bounded and $f : D \to \mathbb{R}$ is Lipschitz, then there is a Lipschitz function $g : \mathbb{R}^r \to \mathbb{R}$, with compact support, extending f. **P** By 262Bb there is a Lipschitz function $f_1 : \mathbb{R}^r \to \mathbb{R}$ which extends f. Let $\gamma > 0$ be such that $D \subseteq B(0, \gamma)$ and γ is a Lipschitz constant for f_1; set $M = |f_1(0)| + \gamma^2$; then $|f_1(x)| \leq M$ for every $x \in D$, so if we set $f_2(x) = \max(-M, \min(f(x), M))$ for $x \in \mathbb{R}^r$, f_2 is a bounded Lipschitz function extending f. Let $f_3(x) = \max(0, 1 - \frac{\|x\|}{\gamma})$ for $x \in \mathbb{R}^r$; then f_3 is a bounded Lipschitz function with compact support. By (a), $g = f_3 \times f_2$ is Lipschitz, and $g : \mathbb{R}^r \to \mathbb{R}$ is a function with compact support extending f. **Q**

(ii) It follows that if $D \subseteq \mathbb{R}^r$ is bounded and $f : D \to \mathbb{R}^s$ is Lipschitz, then there is a Lipschitz function $g : \mathbb{R}^r \to \mathbb{R}^s$, with compact support, extending f. **P** By 262Ba, we need only apply (i) to each coordinate of f. **Q**

473D Smoothing by convolution We shall need a miscellany of facts, many of them special cases of results in §§255 and 444, concerning convolutions on $\mathbb{R}^r$. Recall that I write $(f * g)(x) = \int f(y)g(x-y)\mu(dy)$ whenever f and g are real-valued functions defined almost everywhere in $\mathbb{R}^r$ and the integral is defined. Recall that $f * g = g * f$ (255Fb, 444Og). Now we have the following.

Lemma Suppose that f and g are Lebesgue measurable real-valued functions defined μ-almost everywhere in $\mathbb{R}^r$.

(a) If f is integrable and g is essentially bounded, then their convolution $f * g$ is defined everywhere in $\mathbb{R}^r$ and uniformly continuous, and $\sup_{x \in \mathbb{R}^r} |(f * g)(x)| \leq \|f\|_1 \|g\|_\infty$.

(b) If f is locally integrable and g is bounded and has compact support, then $f * g$ is defined everywhere in $\mathbb{R}^r$ and is continuous.

(c) If f and g are defined everywhere in $\mathbb{R}^r$ and $x \in \mathbb{R}^r \setminus (\{y : f(y) \neq 0\} + \{z : g(z) \neq 0\})$, then $(f * g)(x)$ is defined and equal to 0.

(d) If f is integrable and g is bounded, Lipschitz and defined everywhere, then $f * \operatorname{grad} g$ and $\operatorname{grad}(f * g)$ are defined everywhere and equal, where $f * \operatorname{grad} g = (f * \frac{\partial g}{\partial \xi_1}, \dots, f * \frac{\partial g}{\partial \xi_r})$. Moreover, $f * \operatorname{grad} g = \operatorname{grad}(f * g)$ is Lipschitz.

(e) If f is locally integrable, and $g \in \mathcal{D}$, then $f * g$ is defined everywhere and is smooth.

(f) If f is essentially bounded and $g \in \mathcal{D}$, then $f * g$ is Lipschitz as well as smooth.

(g) If f is integrable and $\phi : \mathbb{R}^r \to \mathbb{R}^r$ is a bounded measurable function with components $\phi_1, \dots, \phi_r$, and we write $(f * \phi)(x) = ((f * \phi_1)(x), \dots, (f * \phi_r)(x))$, then $\|(f * \phi)(x)\| \leq \|f\|_1 \sup_{y \in \mathbb{R}^r} \|\phi(y)\|$ for every $x \in \mathbb{R}^r$.

proof (a) See 255K.

(b) Suppose that $g(y) = 0$ when $\|y\| \geq n$. Given $x \in \mathbb{R}^r$, set $\tilde{f} = f \times \chi B(x, n + 1)$. Then $\tilde{f} * g$ is defined everywhere and continuous, by (a), while $(f * g)(z) = (\tilde{f} * g)(z)$ whenever $z \in B(x, 1)$; so $f * g$ is defined everywhere in $B(x, 1)$ and is continuous at x.

(c) We have only to note that $f(y)g(x - y) = 0$ for every y.

(d) Let γ be a Lipschitz constant for g. We know that $\operatorname{grad} g$ is defined almost everywhere, is measurable, and that $\|\operatorname{grad} g(x)\| \leq \gamma$ whenever it is defined (473Cc); so $(f * \operatorname{grad} g)(x)$ is defined for every x, by (a) here. Fix $x \in \mathbb{R}^r$. If $y, z \in \mathbb{R}^r$ set

$$\theta(y,z) = \frac{1}{\|z\|}\big(g(x-y+z) - g(x-y) - z\,.\,\operatorname{grad} g(x-y)\big)$$

whenever this is defined. Then $|\theta(y,z)| \leq 2\gamma$ whenever it is defined. Now suppose that $\langle z_n\rangle_{n\in\mathbb{N}}$ is a sequence in $\mathbb{R}^r \setminus \{\mathbf{0}\}$ converging to $\mathbf{0}$. Then $\lim_{n\to\infty}\theta(y,z_n) = 0$ whenever $\operatorname{grad} g(x-y)$ is defined, which almost everywhere. So $\lim_{n\to\infty}\int f(y)\theta(y,z_n)\mu(dy) = 0$, by Lebesgue's Dominated Convergence Theorem. But this means that

$$\frac{1}{\|z_n\|}\big((f*g)(x+z_n) - (f*g)(x) - ((f*\operatorname{grad} g)(x))\,.\,z_n\big) \to 0$$

as $n\to\infty$. As $\langle z_n\rangle_{n\in\mathbb{N}}$ is arbitrary, $\operatorname{grad}(f*g)(x)$ is defined and is equal to $(f*\operatorname{grad} g)(x)$.

Now $\operatorname{grad} g$ is bounded, because g is Lipschitz, so $\operatorname{grad}(f*g) = f*\operatorname{grad} g$ is also bounded, by (a), and $f*g$ must be Lipschitz (473Cd).

(e) By (b), $f*g$ is defined everywhere and is continuous. Now, for any $i\leq r$, $\frac{\partial}{\partial\xi_i}(f*g) = f*\frac{\partial g}{\partial\xi_i}$ everywhere. **P** Let $n\in\mathbb{N}$ be such that $g(y)=0$ if $\|y\|\geq n$. Given $x\in\mathbb{R}^r$, set $\tilde f = f\times\chi B(x,n+1)$. Then $(f*g)(z) = (\tilde f*g)(z)$ for every $z\in B(x,1)$, so that

$$\frac{\partial f*g}{\partial\xi_i}(x) = \frac{\partial\tilde f*g}{\partial\xi_i}(x) = (\tilde f*\frac{\partial g}{\partial\xi_i})(x)$$

(by (d))

$$= (f*\frac{\partial g}{\partial\xi_i})(x)$$

(because of course $\frac{\partial g}{\partial\xi_i}$ is also zero outside $B(\mathbf{0},n)$). **Q** Inducing on k,

$$\frac{\partial^k}{\partial\xi_{i_1}\dots\partial\xi_{i_k}}(f*g)(x) = (f*\frac{\partial^k g}{\partial\xi_{i_1}\dots\partial\xi_{i_k}})(x)$$

for every $x\in\mathbb{R}^r$ and every $i_1,\dots,i_k$; so we have the result.

(f) The point is just that all the partial derivatives of g, being smooth functions with compact support, are integrable, and that

$$|\frac{\partial}{\partial\xi_i}(f*g)(x)| = |(f*\frac{\partial g}{\partial\xi})(x)| \leq \|f\|_\infty\|\frac{\partial g}{\partial\xi_i}\|_1$$

for every x and every $i\leq r$. This means that $\operatorname{grad}(f*g)$ is bounded, so that $f*g$ is Lipschitz, by 473Cd.

(g) If x, $z\in\mathbb{R}^r$, then

$$\begin{aligned} z\,.\,(f*\phi)(x) &= \sum_{i=1}^r \zeta_i(f*\phi_i)(x) = \int f(y)\sum_{i=1}^r\zeta_i\phi_i(x-y)\mu(dy)\\ &\leq \int |f(y)|\,|\sum_{i=1}^r\zeta_i\phi_i(x-y)|\mu(dy)\\ &\leq \int |f(y)|\|z\|\|\phi(x-y)\|\mu(dy) \leq \|z\|\|f\|_1\sup_{y\in\mathbb{R}^r}\|\phi(y)\|. \end{aligned}$$

As z is arbitrary, $\|(f*\phi)(x)\|\leq\|f\|_1\sup_{y\in\mathbb{R}^r}\|\phi(y)\|$.

473E Lemma (a) Define $h:\mathbb{R}\to[0,1]$ by setting $h(t) = \exp(\frac{1}{t^2-1})$ for $|t|<1$, 0 for $|t|\geq 1$. Then h is smooth, and $h'(t)\leq 0$ for $t\geq 0$.

(b) For $n\geq 1$, define $\tilde h_n:\mathbb{R}^r\to\mathbb{R}$ by setting

$$\alpha_n = \int h((n+1)^2\|x\|^2)\mu(dx), \quad \tilde h_n(x) = \frac{1}{\alpha_n}h((n+1)^2\|x\|^2)$$

for every $x \in \mathbb{R}^r$. Then $\tilde{h}_n \in \mathcal{D}$, $\tilde{h}_n(x) \geq 0$ for every x, $\tilde{h}_n(x) = 0$ if $\|x\| \geq \frac{1}{n+1}$, and $\int \tilde{h}_n d\mu = 1$.

(c) If $f \in \mathcal{L}^0(\mu)$, then $f(x) = \lim_{n\to\infty}(f * \tilde{h}_n)(x) = f(x)$ for every $x \in \operatorname{dom} f$ at which f is continuous.

(d) If $f : \mathbb{R}^r \to \mathbb{R}$ is uniformly continuous (in particular, if it is either Lipschitz or a continuous function with compact support), then $\lim_{n\to\infty} \|f - f * \tilde{h}_n\|_\infty = 0$.

(e) If $f \in \mathcal{L}^0(\mu)$ is locally integrable, then $f(x) = \lim_{n\to\infty}(f * \tilde{h}_n)(x)$ for μ-almost every $x \in \mathbb{R}^r$.

(f) If $f \in \mathcal{L}^p(\mu)$, where $1 \leq p < \infty$, then $\lim_{n\to\infty} \|f - f * \tilde{h}_n\|_p = 0$.

proof (a) Set $h_0(t) = \exp(-\frac{1}{t})$ for $t > 0$, 0 for $t \leq 0$. A simple induction on n shows that the nth derivative $h_0^{(n)}$ of h_0 is of the form

$$h_0^{(n)}(t) = q_n(\tfrac{1}{t}) \exp(-\tfrac{1}{t}) \text{ for } t > 0,$$
$$= 0 \text{ for } t \leq 0,$$

where each q_n is a polynomial of degree $2n$; the inductive hypothesis depends on the fact that $\lim_{s\to\infty} q(s)e^{-s} = 0$ for every polynomial q. So h_0 is smooth. Now $h(t) = h_0(1 - t^2)$ so h also is smooth. If $0 \leq t < 1$ then

$$h'(t) = -\exp(\tfrac{1}{t^2-1}) \cdot \tfrac{2t}{(t^2-1)^2} < 0;$$

if $t > 1$ then $h'(t) = 0$; since h' is continuous, $h'(t) \geq 0$ for every $t \geq 0$.

(b) We need only observe that

$$x \mapsto (n+1)^2\|x\|^2 = (n+1)^2 \textstyle\sum_{i=1}^r \xi_i^2$$

is smooth and that the composition of smooth functions is smooth (by 473Bc).

(c) If f is continuous at x and $\epsilon > 0$, let $n_0 \in \mathbb{N}$ be such that $|f(y) - f(x)| \leq \epsilon$ whenever $y \in \operatorname{dom} f$ and $\|y - x\| \leq \frac{1}{n_0+1}$. Then for any $n \geq n_0$,

$$\begin{aligned}|(f * \tilde{h}_n)(x) - f(x)| &= |\int f(x-y)\tilde{h}_n(y)\mu(dy) - \int f(x)\tilde{h}_n(y)\mu(dy)| \\ &\leq \int |f(x-y) - f(x)|\tilde{h}_n(y)\mu(dy) \leq \int \epsilon\tilde{h}_n(y)\mu(dy) = \epsilon.\end{aligned}$$

As ϵ is arbitrary, we have the result.

(d) Repeat the argument of (c), but 'uniformly in x'; that is, given $\epsilon > 0$, take n_0 such that $|f(y) - f(x)| \leq \epsilon$ whenever x, $y \in \mathbb{R}^r$ and $\|y - x\| \leq \frac{1}{n_0+1}$, and see that $|(f * \tilde{h}_n)(x) - f(x)| \leq \epsilon$ for every $n \geq n_0$ and every x.

(e) We know from 472Db or 261E that, for almost every $x \in \mathbb{R}^r$,

$$\lim_{\delta\downarrow 0} \tfrac{1}{\mu B(x,\delta)} \textstyle\int_{B(x,\delta)} |f(y) - f(x)|\mu(dy) = 0.$$

Take any such x. Set $\gamma = f(x)$, Set $g(y) = |f(y) - \gamma|$ for every $y \in \operatorname{dom} f$. Let $\epsilon > 0$. Then there is some $\delta > 0$ such that $\frac{q(t)}{\beta_r t^r} \leq \epsilon$ whenever $0 < t \leq \delta$, where

$$q(t) = \textstyle\int_{B(x,t)} g\, d\mu = \int_0^t \int_{\partial B(x,s)} g(y)\nu(dy)dt$$

by 265G, so $q'(t) = \int_{\partial B(y,t)} g\, d\nu$ for almost every $t \in [0, \delta]$, by 222E. If $n + 1 \geq \frac{1}{\delta}$, then

$$\begin{aligned}(g * \tilde{h}_n)(x) &= \int g(y)\tilde{h}_n(x-y)\mu(dy) = \int_{B(x,\delta)} g(y)\tilde{h}_n(x-y)\mu(dy) \\ &= \frac{1}{\alpha_n}\int_0^\delta \int_{\partial B(x,t)} g(y)h((n+1)^2t^2)\nu(dy)dt\end{aligned}$$

(265G again)

$$= \frac{1}{\alpha_n}\int_0^\delta h((n+1)^2t^2)q'(t)dt$$
$$= -\frac{1}{\alpha_n}\int_0^\delta 2(n+1)^2h'((n+1)^2t^2)q(t)dt$$

(integrating by parts (225F), because $q(0) = h((n+1)^2\delta^2) = 0$ and both q and h are absolutely continuous)

$$\leq -\frac{\epsilon}{\alpha_n}\int_0^\delta 2(n+1)^2h'((n+1)^2t^2)\beta_r t^r dt$$

(because $0 \leq q(t) \leq \epsilon\beta_r t^r$ and $h'((n+1)^2t^2) \leq 0$ for $0 \leq t \leq \delta$)

$$= \epsilon$$

(applying the same calculations with $\chi\mathbb{R}^r$ in place of g). But now, since $(\gamma\chi\mathbb{R}^r * \tilde{h}_n)(x) = \gamma$ for every n,

$$|(f * \tilde{h}_n)(x) - \gamma| = |\int (f(y)-\gamma)\tilde{h}_n(x-y)\mu(dy)| \leq \int |f(y)-\gamma|\tilde{h}_n(x-y)\mu(dy) \leq \epsilon$$

whenever $n+1 \geq \frac{1}{\delta}$. As ϵ is arbitrary, $f(x) = \gamma = \lim_{n\to\infty}(f * \tilde{h}_n)(x)$; and this is true for μ-almost every x.

(f) Apply 444T with ν the indefinite-integral measure over μ defined by $\tilde{h}_n$; use 444P for the identification of $\nu * f$ with $\tilde{h}_n * f = f * \tilde{h}_n$.

473F Lemma For any measure space (X, Σ, λ) and any non-negative $f_1, \dots, f_k \in \mathcal{L}^0(\lambda)$,

$$\int \prod_{i=1}^k f_i^{1/k} d\lambda \leq \prod_{i=1}^k \big(\int f_i d\lambda\big)^{1/k}.$$

proof Induce on k. Note that we can suppose that every f_i is integrable; for if any $\int f_i$ is zero, then $f_i = 0$ a.e. and the result is trivial; and if all the $\int f_i$ are greater than zero and any of them is infinite, the result is again trivial.

The induction starts with the trivial case $k = 1$. For the inductive step to $k \geq 2$, we have

$$\int \prod_{i=1}^k f_i^{1/k} d\lambda \leq \| \prod_{i=1}^{k-1} f_i^{1/k}\|_{k/(k-1)} \|f_k^{1/k}\|_k$$

(by Hölder's inequality, 244E)

$$= \big(\int \prod_{i=1}^{k-1} f_i^{1/(k-1)} d\lambda\big)^{(k-1)/k} \big(\int f_k d\lambda\big)^{1/k}$$
$$\leq \big(\prod_{i=1}^{k-1} (\int f_i d\lambda)^{1/(k-1)}\big)^{(k-1)/k} \big(\int f_k d\lambda\big)^{1/k}$$

(by the inductive hypothesis)

$$= \prod_{i=1}^k (\int f_i d\lambda)^{1/k},$$

as required.

473F Lemma Let (X, Σ, λ) be a σ-finite measure space and $k \geq 2$ an integer. Write λ_k for the product measure on X^k. For $x = (\xi_1, \dots, \xi_k) \in X^k$, $t \in X$, $1 \leq i \leq k$ set $S_i(x,t) = (\xi_1', \dots, \xi_k')$ where $\xi_i' = t$ and $\xi_j' = \xi_j$ for $j \neq i$. Then if $h \in \mathcal{L}^1(\lambda_k)$ is non-negative, and we set $h_i(x) = \int S_i(x,t)\lambda(dt)$ whenever this is defined in $\mathbb{R}$, we have

$$\int (\prod_{i=1}^k h_i)^{1/(k-1)} d\lambda_k \leq (\int h\, d\lambda_k)^{k/(k-1)}.$$

proof Induce on k.

(a) If $k = 2$, we have

$$\begin{aligned}\int h_1 \times h_2 d\lambda_k &= \iint \big(\int h(\tau_1, \xi_2) d\tau_1\big)\big(\int h(\xi_1, \tau_2) d\tau_2\big) d\xi_1 d\xi_2 \\ &= \iiint\int h(\tau_1, \xi_2) h(\xi_1, \tau_2) d\tau_1 d\tau_2 d\xi_1 d\xi_2 \\ &= \iint h(\tau_1, \xi_2) d\tau_1 d\xi_2 \cdot \iint h(\xi_1, \tau_2) d\tau_2 d\xi_1 = \big(\int h \, d\lambda_2\big)^2\end{aligned}$$

by Fubini's theorem (252B) used repeatedly, because (by 253D) $(\tau_1, \tau_2, \xi_1, \xi_2) \mapsto h(\xi_1, \tau_2) h(\tau_1, \xi_2)$ is λ_4-integrable. (See 251W for a sketch of the manipulations needed to apply 252B, as stated, to the integrals above.)

(b) For the inductive step to $k \geq 3$, argue as follows. For $y \in X^{k-1}$, set $g(y) = \int h(y,t) dt$ whenever this is defined in $\mathbb{R}$, identifying X^k with $X^{k-1} \times X$, so that $g(y) = h_k(y,t)$ whenever either is defined. If $1 \leq i < k$, we can consider $S_i(y,t)$ for $y \in X^{k-1}$ and $t \in X$, and we have

$$\int g(S_i(y,t)) dt = \iint h(S_i(y,t), u) du dt = \int h_i(y,t) dt$$

for almost every $y \in X^{k-1}$. So

$$\begin{aligned}\int (\prod_{i=1}^{k} h_i)^{1/(k-1)} d\lambda_k &= \iint (\prod_{i=1}^{k-1} h_i(y,t))^{1/(k-1)} g(y)^{1/(k-1)} dt \, \lambda_{k-1}(dy) \\ &= \int g(y)^{1/(k-1)} \int (\prod_{i=1}^{k-1} h_i(y,t))^{1/(k-1)} dt \, \lambda_{k-1}(dy) \\ &\leq \int g(y)^{1/(k-1)} \prod_{i=1}^{k-1} \big(\int h_i(y,t) dt\big)^{1/(k-1)} \lambda_{k-1}(dy)\end{aligned}$$

(473F)

$$= \int g(y)^{1/(k-1)} \prod_{i=1}^{k-1} g_i(y)^{1/(k-1)} \lambda_{k-1}(dy)$$

(where g_i is defined from g in the same way as h_i is defined from h)

$$\leq \big(\int g(y) \lambda_{k-1}(dy)\big)^{1/(k-1)} \big(\int \prod_{i=1}^{k-1} g_i(y)^{1/(k-2)} \lambda_{k-1}(dy)\big)^{(k-2)/(k-1)}$$

(by Hölder's inequality again, this time with $\frac{1}{k-1} + \frac{k-2}{k-1} = 1$)

$$\leq \big(\int g(y) \lambda_{k-1}(dy)\big)^{1/(k-1)} \cdot \int g(y) \lambda_{k-1}(dy)$$

(by the inductive hypothesis)

$$= \big(\int g(y) \lambda_{k-1}(dy)\big)^{k/(k-1)} = \big(\int h(x) \lambda_k(dx)\big)^{k/(k-1)},$$

and the induction proceeds.

473H Gagliardo-Nirenberg-Sobolev inequality Suppose that $f : \mathbb{R}^r \to \mathbb{R}$ is a Lipschitz function with compact support. Then $\|f\|_{r/(r-1)} \leq \int \|\operatorname{grad} f\| d\mu$.

proof By 473Cc, $\operatorname{grad} f$ is measurable and bounded, so $\|\operatorname{grad} f\|$ also is; since it must have compact support, it is integrable.

For $1 \leq i \leq r$, $x = (\xi_1, \ldots, \xi_r) \in \mathbb{R}^r$ and $t \in \mathbb{R}$ write $S_i(x,t) = (\xi_1', \ldots, \xi_r')$ where $\xi_i' = t$ and $\xi_j' = \xi_j$ for $j \neq i$. Set $h_i(x) = \int_{-\infty}^{\infty} \|\operatorname{grad} f(S_i(x,t))\| dt$ when this is defined, which will be the case for almost every x. Now, whenever $h_i(x)$ is defined,

$$|f(x)| = |f(S_i(x,\xi_i))| = |\int_{-\infty}^{\xi_i} \tfrac{\partial}{\partial t} f(S_i(x,t))dt| \leq h_i(x).$$

(Use 225E and the fact that a Lipschitz function on any bounded interval in $\mathbb{R}$ is absolutely continuous.) So $|f| \leq_{\text{a.e.}} h_i$ for every $i \leq r$. Accordingly

$$\int |f(x)|^{r/(r-1)}\mu(dx) \leq \int \prod_{i=1}^r h_i(x)^{1/(r-1)}\mu(dx) \leq \big(\int \|\operatorname{grad} f(x)\|\mu(dx)\big)^{r/(r-1)}$$

by 473F. Raising both sides to the power $(r-1)/r$ we have the result.

473I Lemma For any Lipschitz function $f : B(\mathbf{0},1) \to \mathbb{R}$,

$$\int_{B(\mathbf{0},1)} |f|^{r/(r-1)}d\mu \leq \big(2^{r+2}(1+\sqrt{r})\int_{B(\mathbf{0},1)} \|\operatorname{grad} f\| + |f|d\mu\big)^{r/(r-1)}.$$

proof (a) Set $g(x) = \max(0, 2\|x\|^2 - 1)$ for $x \in B(\mathbf{0},1)$. Then $\operatorname{grad} g$ is defined at every point x such that $\|x\| < 1$ and $\|x\| \neq \sqrt{2}$, and at all such points $\frac{\partial g}{\partial \xi_i}$ is either 0 or $4\xi_i$ for each i, so that $\|\operatorname{grad} g(x)\| \leq 4\|x\| \leq 4$. Hence (or otherwise) g is Lipschitz. So $f_1 = f \times g$ is Lipschitz (473Ca).

By Rademacher's theorem again, $\operatorname{grad} f_1$ is defined almost everywhere in $B(\mathbf{0},1)$. Now

$$\begin{aligned}\int_{B(\mathbf{0},1)} \|\operatorname{grad} f_1\| &= \int_{B(\mathbf{0},1)} \|f(x)\operatorname{grad} g(x) + g(x)\operatorname{grad} f(x)\|\mu(dx)\\ &\leq \int_{B(\mathbf{0},1)} 4|f| + \|\operatorname{grad} f\|d\mu.\end{aligned} \tag{473Bd}$$

(b) It will be convenient to have an elementary fact out in the open. Set $\phi(x) = \frac{x}{\|x\|^2}$ for $x \in \mathbb{R}^r \setminus \{\mathbf{0}\}$; note that $\phi^2(x) = x$. Then $\phi\restriction \mathbb{R}^r \setminus B(\mathbf{0},\delta)$ is Lipschitz, for any $\delta > 0$. **P** If $\|x\| = \alpha \geq \delta$, $\|y\| = \beta \geq \delta$, then we have

$$\begin{aligned}\|\phi(x) - \phi(y)\|^2 &= \tfrac{1}{\alpha^4}\|x\|^2 - \tfrac{2}{\alpha^2\beta^2}x\boldsymbol{.}y + \tfrac{1}{\beta^4}\|y\|^2\\ &= \tfrac{1}{\alpha^2\beta^2}\big(\|y\|^2 - 2x\boldsymbol{.}y + \|x\|^2\big) \leq \tfrac{1}{\delta^4}\|x-y\|^2,\end{aligned}$$

so $\frac{1}{\delta^2}$ is a Lipschitz constant for $\phi\restriction \mathbb{R}^r \setminus B(\mathbf{0},\delta)$. **Q**

(c) Set $f_2(x) = f(x)$ if $\|x\| \leq 1$, $f_1\phi(x)$ if $\|x\| \geq 1$. Then f_2 is well-defined (because $f_1(x) = f(x)$ if $\|x\| = 1$), is zero outside $B(\mathbf{0},\sqrt{2})$ (because $g(x) = 0$ if $\|x\| \leq \frac{1}{\sqrt{2}}$), and is Lipschitz. **P** By 473Cb, it will be enough to show that $f_2\restriction F$ is Lipschitz, where $F = \{x : \|x\| \geq 1\}$. But (b) shows that $\phi\restriction F$ is 1-Lipschitz on F, so any Lipschitz constant for f_1 is also a Lipschitz constant for $f_2\restriction F$. **Q**

If $\|x\| > 1$, then, for any $i \leq r$,

$$\begin{aligned}\tfrac{\partial f_2}{\partial \xi_i}(x) &= \sum_{j=1}^r \tfrac{\partial f_1}{\partial \xi_j}(\phi(x)) \cdot \tfrac{\partial}{\partial \xi_i}(\tfrac{\xi_j}{\|x\|^2})\\ &= \tfrac{\partial f_1}{\partial \xi_i}(\phi(x)) \cdot \tfrac{1}{\|x\|^2} - \sum_{j=1}^r \tfrac{\partial f}{\partial \xi_j}(\phi(x)) \cdot \tfrac{\xi_i\xi_j}{\|x\|^4}\end{aligned}$$

wherever the right-hand side is defined, that is, wherever all the partial derivatives $\frac{\partial f_1}{\partial \xi_i}(\phi(x))$ are defined. But $H = B(\mathbf{0},1) \setminus \operatorname{dom}(\operatorname{grad} f_1)$ is negligible, and does not meet $\{x : \|x\| < \sqrt{2}\}$, so $\phi\restriction H$ is Lipschitz and $\phi[H] = \phi^{-1}[H]$ is negligible (262D); while $\operatorname{grad} f_1(\phi(x))$ is defined whenever $\|x\| > 1$ and $x \notin \phi^{-1}[H]$. So the formula here is valid for almost every $x \in F$, and

$$|\frac{\partial f_2}{\partial \xi_i}(x)| \leq \|\operatorname{grad} f_1(\phi(x))\| \cdot \frac{1}{\|x\|^2} + \|\operatorname{grad} f_1(\phi(x))\| \cdot \frac{|\xi_i|}{\|x\|^4} \sqrt{\sum_{j=1}^{r} \xi_j^2}$$

$$= \|\operatorname{grad} f_1(\phi(x))\| \frac{\|x\|+|\xi_i|}{\|x\|^3}$$

for almost every $x \in F$. But (since we know that $\operatorname{grad} f_2$ is defined almost everywhere, by Rademacher's theorem, as usual) we have

$$\|\operatorname{grad} f_2(x)\| \leq \frac{1+\sqrt{r}}{\|x\|^2} \|\operatorname{grad} f_1(\phi(x))\| \leq (1+\sqrt{r}) \|\operatorname{grad} f_1(\phi(x))\|$$

for almost every $x \in F$.

(c) We are now in a position to estimate

$$\int_F \|\operatorname{grad} f_2\| d\mu = \int_{B(\mathbf{0},\sqrt{2})} \|\operatorname{grad} f_2\| d\mu - \int_{B(\mathbf{0},1)} \|\operatorname{grad} f_2\| d\mu$$

(because $\operatorname{grad} f_1(x) = \mathbf{0}$ if $\|x\| < \sqrt{2}$)

$$= \int_1^{\sqrt{2}} \int_{\partial B(\mathbf{0},t)} \|\operatorname{grad} f_2(x)\| \nu(dx) dt$$

(265G, as usual)

$$\leq (1+\sqrt{r}) \int_1^{\sqrt{2}} \int_{\partial B(\mathbf{0},t)} \|\operatorname{grad} f_1(\tfrac{1}{t^2}x)\| \nu(dx) dt$$

(by (b) above)

$$\leq (1+\sqrt{r}) \int_1^{\sqrt{2}} \int_{\partial B(\mathbf{0},1/t)} t^{2r-2} \|\operatorname{grad} f_1(y)\| \nu(dy) dt$$

substituting $x = t^2 y$ in the inner integral; the point being that as the function $y \mapsto t^2 y$ changes all distances by a scalar multiple t^2, it must transform Hausdorff $r-1$-dimensional measure by a multiple t^{2r-2}. But now, substituting $s = \frac{1}{t}$ in the outer integral, we have

$$\begin{aligned}
\int_F \|\operatorname{grad} f_2\| d\mu &\leq (1+\sqrt{r}) \int_{1/\sqrt{2}}^1 \frac{1}{s^{2r}} \int_{\partial B(\mathbf{0},s)} \|\operatorname{grad} f_1(y)\| \nu(dy) ds \\
&\leq 2^r (1+\sqrt{r}) \int_{1/\sqrt{2}}^1 \int_{\partial B(\mathbf{0},s)} \|\operatorname{grad} f_1(y)\| \nu(dy) ds \\
&= 2^r (1+\sqrt{r}) \int_{B(\mathbf{0},1)} \|\operatorname{grad} f_1\| d\mu \\
&\leq 2^r (1+\sqrt{r}) \int_{B(\mathbf{0},1)} 4|f| + \|\operatorname{grad} f\| d\mu.
\end{aligned}$$

by (a) above.

(d) Accordingly

$$\begin{aligned}
\int_{\mathbb{R}^r} \|\operatorname{grad} f_2\| d\mu &\leq \int_{B(\mathbf{0},1)} \|\operatorname{grad} f\| d\mu + \int_F \|\operatorname{grad} f_2\| d\mu \\
&\leq 2^{r+2} (1+\sqrt{r}) \int_{B(\mathbf{0},1)} |f| + \|\operatorname{grad} f\| d\mu.
\end{aligned}$$

But now we can apply 473H to see that

$$\int_{B(\mathbf{0},1)} |f|^{r/(r-1)}d\mu \leq \int |f_2|^{r/r-1}d\mu \leq (\int \|\operatorname{grad} f_2\|d\mu)^{r/(r-1)}$$
$$\leq \big(2^{r+2}(1+\sqrt{r})\int_{B(\mathbf{0},1)} |f| + \|\operatorname{grad} f\|d\mu\big)^{r/(r-1)},$$

as claimed.

473J Lemma Let $f : \mathbb{R}^r \to \mathbb{R}$ be a Lipschitz function. Then

$$\int_{B(y,\delta)} |f(x) - f(z)|\mu(dx) \leq \frac{2^r}{r}\delta^r \int_{B(y,\delta)} \|\operatorname{grad} f(x)\|\|x-z\|^{1-r}\mu(dx)$$

whenever $y \in \mathbb{R}^r$, $\delta > 0$ and $z \in B(y,\delta)$.

proof (a) To begin with, suppose that f is smooth. In this case, for any x, $z \in B(y,\delta)$,

$$|f(x) - f(z)| = \big|\int_0^1 \frac{d}{dt} f(z + t(x-z))dt\big|$$
$$= \big|\int_0^1 (x-z)\,.\operatorname{grad} f(z+t(x-z))dt\big|$$
$$\leq \|x-z\| \int_0^1 \|\operatorname{grad} f(z+t(x-z))\|dt.$$

So, for $\eta > 0$,

$$\int_{B(y,\delta)\cap\partial B(z,\eta)} |f(x) - f(z)|\nu(dx)$$
$$\leq \eta \int_0^1 \int_{B(y,\delta)\cap\partial B(z,\eta)} \|\operatorname{grad} f(z+t(x-z))\|\nu(dx)dt$$

(grad f is continuous and bounded, and the subspace measure induced by ν on $\partial B(z,\eta)$ is a (quasi-)Radon measure (471E, 471Dh), so its product with Lebesgue measure also is (417T), and there is no difficulty with the change in order of integration)

$$= \eta \int_0^1 \frac{1}{t^{r-1}} \int_{B(y,\delta)\cap\partial B(z,t\eta)} \|\operatorname{grad} f(w)\|\nu(dw)dt$$

(because if $\phi(x) = z + t(x-z)$, then $\nu\phi^{-1}[E] = \frac{1}{t^{r-1}}\nu E$ whenever ν measures E and $t > 0$)

$$= \eta^r \int_0^1 \int_{B(y,\delta)\cap\partial B(z,t\eta)} \|\operatorname{grad} f(w)\|\|w-z\|^{1-r}\nu(dw)dt$$
$$= \eta^{r-1} \int_0^\eta \int_{B(y,\delta)\cap\partial B(z,s)} \|\operatorname{grad} f(w)\|\|w-z\|^{1-r}\nu(dw)ds$$

(substituting $s = t\eta$)

$$= \eta^{r-1} \int_{B(y,\delta)\cap B(z,\eta)} \|\operatorname{grad} f(w)\|\|w-z\|^{1-r}\mu(dw)$$

by 265G. By 265G again,

$$\begin{aligned}\int_{B(y,\delta)} |f(x)-f(z)|\mu(dx) &= \int_0^{2\delta}\int_{B(y,\delta)\cap\partial B(z,\eta)} |f(x)-f(z)|\nu(dx)d\eta\\ &\le \int_0^{2\delta}\eta^{r-1}\int_{B(y,\delta)\cap B(z,\eta)} \|\operatorname{grad} f(w)\|\|w-z\|^{1-r}\mu(dw)d\eta\\ &\le \int_0^{2\delta}\eta^{r-1}\int_{B(y,\delta)} \|\operatorname{grad} f(w)\|\|w-z\|^{1-r}\mu(dw)d\eta\\ &= \frac{2^r}{r}\delta^r\int_{B(y,\delta)} \|\operatorname{grad} f(w)\|\|w-z\|^{1-r}\mu(dw).\end{aligned}$$

(b) Now turn to the general case in which f is not necessarily differentiable everywhere, but is known to be Lipschitz. We need to know that $\int_{B(y,\delta)}\|x-z\|^{1-r}\mu(dx)$ is finite; this is because

$$\int_{B(y,\delta)}\|x-z\|^{1-r}\mu(dx) \le \int_{B(z,2\delta)}\|x-z\|^{1-r}\mu(dx) = \int_0^{2\delta} t^{1-r}\nu(\partial B(z,t))dt$$

(265G once more)

$$= \int_0^{2\delta} t^{1-r}r\beta_r t^{r-1}dt = 2\delta r\beta_r.$$

Now take the sequence $\langle\tilde{h}_n\rangle_{n\in\mathbb{N}}$ from 473E. Then $\langle f*\tilde{h}_n\rangle_{n\in\mathbb{N}}$ converges uniformly to f (473Ed), while $\langle\operatorname{grad}(f*\tilde{h}_n)\rangle_{n\in\mathbb{N}} = \langle\tilde{h}_n*\operatorname{grad} f\rangle_{n\in\mathbb{N}}$ (473Dd) is uniformly bounded (473Cc, 473Dg) and converges almost everywhere to $\operatorname{grad} f$ (473Ee). But this means that, setting $f_n = f*\tilde{h}_n$,

$$\begin{aligned}\int_{B(y,\delta)} |f(x)-f(z)|\mu(dx) &= \lim_{n\to\infty}\int_{B(y,\delta)} |f_n(x)-f_n(z)|\mu(dx)\\ &\le \lim_{n\to\infty}\frac{2^r}{r}\delta^r\int_{B(y,\delta)} \|\operatorname{grad} f_n(x)\|\|x-z\|^{1-r}\mu(dx)\end{aligned}$$

(because every f_n is differentiable, by 473De)

$$= \frac{2^r}{r}\delta^r\int_{B(y,\delta)} \|\operatorname{grad} f(x)\|\|x-z\|^{1-r}\mu(dx)$$

by Lebesgue's Dominated Convergence Theorem.

473K Poincaré's inequality for balls Let $B\subseteq\mathbb{R}^r$ be a non-trivial closed ball, and $f : B\to\mathbb{R}$ a Lipschitz function. Set $\gamma = \frac{1}{\mu B}\int_B f d\mu$. Then

$$\big(\int_B |f-\gamma|^{r/(r-1)}d\mu\big)^{(r-1)/r} \le c\int_B \|\operatorname{grad} f\|d\mu,$$

where $c = 2^{r+2}(1+\sqrt{r})(1+2^{r+1})$.

proof (a) To begin with (down to the end of (b)) suppose that B is the unit ball $B(\mathbf{0},1)$. Then, for any $x\in B$,

$$\begin{aligned}|f(x)-\gamma| &= \frac{1}{\mu B}\big|\int_B f(x)-f(z)\mu(dz)\big|\\ &\le \frac{1}{\mu B}\int_B |f(x)-f(z)|\mu(dz)\\ &\le \frac{2^r}{r}\cdot\frac{1}{\mu B}\int_B \|\operatorname{grad} f(z)\|\|z-x\|^{1-r}\mu(dz),\end{aligned}$$

by 473J. Also

$$\int_{B(z,2)} \|x-z\|^{1-r}\mu(dx) = \int_0^2 \int_{\partial B(z,t)} \|x-z\|^{1-r}\nu(dx)dt$$

(265G)

$$= \int_0^2 t^{1-r}\nu(\partial B(z,t))dt = \int_0^1 t^{1-r}t^{r-1}\nu(\partial B(\mathbf{0},1))dt$$
$$= 2\nu(\partial B(\mathbf{0},1)) = 2r\beta_r$$

by 265H. So

$$\begin{aligned}\int_B |f(x)-\gamma|\mu(dx) &\le \frac{2^r}{r}\cdot\frac{1}{\mu B}\int_B\int_B \|\operatorname{grad} f(z)\|\|z-x\|^{1-r}\mu(dz)\mu(dx)\\ &= \frac{2^r}{r\beta_r}\int_B\int_B \|\operatorname{grad} f(z)\|\|z-x\|^{1-r}\mu(dx)\mu(dz)\\ &\le \frac{2^r}{r\beta_r}\int_B \|\operatorname{grad} f(z)\|\int_{B(z,2)}\|z-x\|^{1-r}\mu(dx)\mu(dz)\\ &\le 2^{r+1}\int_B \|\operatorname{grad} f(z)\|\mu(dz).\end{aligned}$$

(b) Now apply 473I to $g = f(x)-\gamma$. We have

$$\begin{aligned}\int_B |f-\gamma|^{r/(r-1)}d\mu &\le \big(2^{r+2}(1+\sqrt{r})\int_B \|\operatorname{grad} f\| + |g|d\mu\big)^{r/(r-1)}\\ &\le \big(2^{r+2}(1+\sqrt{r})(1+2^{r+1})\int_B \|\operatorname{grad} f\|d\mu\big)^{r/(r-1)}\end{aligned}$$

(by (a))

$$= \big(c\int_B \|\operatorname{grad} f\|d\mu\big)^{r/(r-1)}.$$

(c) For the general case, express B as $B(y,\delta)$, and set $h(x) = f(y+\delta x)$ for $x \in B(\mathbf{0},1)$. Then $\operatorname{grad} h(x) = \delta \operatorname{grad} f(y+\delta x)$ for almost every $x \in B(\mathbf{0},1)$. Now

$$\textstyle\int_{B(\mathbf{0},1)} h\,d\mu = \frac{1}{\delta^r}\int_{B(y,\delta)} f d\mu,$$

so

$$\textstyle\frac{1}{\mu B(\mathbf{0},1)}\int_{B(\mathbf{0},1)} h d\mu = \frac{1}{\mu B(y,\delta)}\int_{B(y,\delta)} f d\mu = \gamma.$$

We therefore have

$$\begin{aligned}\int_{B(y,\delta)} |f-\gamma|^{r/(r-1)}d\mu &= \delta^r\int_{B(\mathbf{0},1)} |h-\gamma|^{r/(r-1)}d\mu\\ &\le \delta^r\big(c\int_{B(\mathbf{0},1)}\|\operatorname{grad} h\|d\mu\big)^{r/(r-1)}\end{aligned}$$

(by (a)-(b) above)

$$\begin{aligned}&= \delta^r\big(\tfrac{\delta c}{\delta^r}\int_{B(y,\delta)}\|\operatorname{grad} f\|d\mu\big)^{r/(r-1)}\\ &= \big(c\int_{B(y,\delta)}\|\operatorname{grad} f\|d\mu\big)^{r/(r-1)}.\end{aligned}$$

Raising both sides to the power $(r-1)/r$ we have the result as stated.

Remark As will be plain from the way in which the proof here is constructed, there is no suggestion that the formula offered for c gives anything near the best possible value.

473L Corollary Let $B \subseteq \mathbb{R}^r$ be a non-trivial closed ball, and $f : B \to [0,1]$ a Lipschitz function. Set

$$F_0 = \{x : x \in B,\, f(x) \leq \tfrac{1}{4}\}, \quad F_1 = \{x : x \in B,\, f(x) \geq \tfrac{3}{4}\}.$$

Then

$$\big(\min(\mu F_0, \mu F_1)\big)^{(r-1)/r} \leq 4c \int_B \|\operatorname{grad} f\| d\mu,$$

where $c = 2^{r+2}(1+\sqrt{r})(1+2^{r+1})$.

proof Setting $\gamma = \frac{1}{\mu B}\int_B f d\mu$,

$$\int_B |f-\gamma|^{r/(r-1)} d\mu \geq \tfrac{1}{4^{r/(r-1)}}\mu F_0 \text{ if } \gamma \geq \tfrac{1}{2},$$
$$\geq \tfrac{1}{4^{r/(r-1)}}\mu F_1 \text{ if } \gamma \leq \tfrac{1}{2}.$$

So 473K tells us that

$$\tfrac{1}{4}\big(\min(\mu F_0, \mu F_1)\big)^{(r-1)/r} \leq c \int_B \|\operatorname{grad} f\| d\mu,$$

as required.

473M The case $r = 1$ The general rubric for this section declares that r is taken to be at least 2, which is clearly necessary for the formula in 475J to be appropriate. For the sake of an application in the next section, however, I mention the elementary corresponding result when $r = 1$. In this case, B is just a closed interval, and $\operatorname{grad} f$ is the ordinary deriivative of f; interpreting $(\int_B |f-\gamma|^{r/(r-1)})^{(r-1)/r}$ as $\|f \times \chi B - \gamma \chi B\|_{r/(r-1)}$, it is natural to look at

$$\|f \times \chi B - \gamma \chi B\|_\infty = \sup_{x \in B} |f(x) - \gamma| \leq \sup_{x,y \in B} |f(x) - f(y)| \leq \int_B |f'| d\mu,$$

giving a version of 473K for $r = 1$. We see that the formula for c remains valid in the case $r = 1$, with a good deal to spare. As for 473L, if $\int_B |f'| < \frac{1}{2}$ then at least one of F_0, F_1 must be empty.

473X Basic exercises (a) Set $f(x) = \max(0, -\ln\|x\|)$, $f_k(x) = \min(k, f(x))$ for $x \in \mathbb{R}^2 \setminus \{0\}$, $k \in \mathbb{N}$. Show that $\lim_{k\to\infty} \|f - f_k\|_2 = \lim_{k\to\infty} \|\operatorname{grad} f - \operatorname{grad} f_k\|_1 = 0$, so that all the inequalities 473H-473L are valid for f.

(b) Let $k \in [1, r]$ be an integer, and set $m = \frac{(r-1)!}{(k-1)!(r-k)!}$. Let $e_1, \ldots, e_r$ be the standard orthonormal basis of $\mathbb{R}^r$ and $\mathcal{J}$ the family of subsets of $\{1, \ldots, r\}$ with k members. For $J \in \mathcal{J}$ let V_J be the linear span of $\{e_i : i \in J\}$, $\pi_J : \mathbb{R}^r \to V_J$ the orthogonal projection and ν_J the normalized k-dimensional Hausdorff measure on V_J. Show that if $A \subseteq \mathbb{R}^r$ then $(\mu^* A)^m \leq \prod_{J\in\mathcal{J}} \nu_J^* \pi_J[A]$. (*Hint*: start with $A \subseteq [0,1]^r$ and note that $([0,1]^r)^m$ can be identified with $\prod_{J\in\mathcal{J}} [0,1]^J$.)

473Y Further exercises (a) Let $D \subseteq \mathbb{R}^r$ be any set and $\phi : D \to \mathbb{R}^s$ any function. Show that $D_0 = \{x : x \in D, \phi \text{ is differentiable at } x\}$ is a Borel subset of $\mathbb{R}^r$, and that the derivative of ϕ is a Borel measurable function. (Compare 225J.)

473 Notes and comments The point of all the inequalities 473H-473L is that they bound some measure of variance of a function f by the integral of $\|\operatorname{grad} f\|$. If $r = 2$, indeed, we are looking at $\|f\|_2$ (473H) or $\int_B |f|^2$ (473I) or something essentially equal to the variance of probability theory (473K). In higher dimensions we need to look at $\|\,\|_{r/(r-1)}$ in place of $\|\,\|_2$, and when $r = 1$ we can interpret the inequalities in terms of the supremum norm $\|\,\|_\infty$ (473M). In all cases we want to develop inequalities which will enable us to discuss a function in terms of its first derivative. In one dimension, this is the familiar Fundamental Theorem of Calculus (Chapter 22). We find there a straightforward criterion ('absolute continuity') to determine whether a given function of one variable is an indefinite integral, and that if so it is the indefinite integral of its own derivative. Even in two dimensions, this simplicity disappears. The essential problem is that a

function can be the indefinite integral of an integrable gradient function without being bounded (473Xa). The principal results of this section are stated for Lipschitz functions, but in fact they apply much more widely. The argument suggested in 473Xa involves approximating the unbounded function f by Lipschitz functions f_k in a sharp enough sense to make it possible to read off all the inequalities for f from the corresponding inequalities for the f_k. This idea leads naturally to the concept of 'Sobolev space', which I leave on one side for the moment; see EVANS & GARIEPY 92, chap. 4, for details.

474 The distributional perimeter

The next step is a dramatic excursion, defining (for appropriate sets E) a perimeter *measure* for which a version of the Divergence Theorem is true (474E). I begin the section with elementary notes on the divergence of a vector field (474B-474C). I then define 'locally finite perimeter' (474D), 'perimeter measure' and 'outward normal' (474F) and 'reduced boundary' (474H). The definitions rely on the Riesz representation theorem, and we have to work very hard to relate them to any geometrically natural idea of 'boundary'. Even half-spaces (474I) demand some attention. From Poincaré's inequality (473K) we can prove isoperimetric inequalities for perimeter measures (474L). With some effort we can locate the reduced boundary as a subset of the topological boundary (474Xc), and obtain asymptotic inequalities on the perimeter measures of small balls (474N). With much more effort we can find a geometric description of outward normal functions in terms of 'Federer exterior normals' (474Q), and get a tight asymptotic description of the perimeter measures of small balls (474R). I end with the Compactness Theorem for sets of bounded perimeter (474S).

474A Notation I had better repeat some of the notation from §473. $r \geq 2$ is a fixed integer. μ is Lebesgue measure on $\mathbb{R}^r$, and $\beta_r = \mu B(\mathbf{0}, 1)$ is the volume of the unit ball. $S_{r-1} = \partial B(\mathbf{0}, 1)$ is the unit sphere. ν is normalized $r-1$-dimensional Hausdorff measure on $\mathbb{R}^r$. We shall sometimes need to look at Lebesgue measure on $\mathbb{R}^{r-1}$, which I will denote μ_{r-1}.

$\mathcal{D}$ is the set of smooth functions $f : \mathbb{R}^r \to \mathbb{R}$ with compact support; $\mathcal{D}_r$ the set of smooth functions $\phi : \mathbb{R}^r \to \mathbb{R}^r$ with compact support, that is, the set of functions $\phi = (\phi_1, \ldots, \phi_r) : \mathbb{R}^r \to \mathbb{R}^r$ such that $\phi_i \in \mathcal{D}$ for every i.

I continue to use the sequence $\langle \tilde{h}_n \rangle_{n \in \mathbb{N}}$ from 473E; these functions all belong to $\mathcal{D}$, are non-negative everywhere and zero outside $B(\mathbf{0}, \frac{1}{n+1})$, are even, and have integral 1.

474B The divergence of a vector field (a) For a function ϕ from a subset of $\mathbb{R}^r$ to $\mathbb{R}^r$, write $\operatorname{div} \phi = \sum_{i=1}^r \frac{\partial \phi_i}{\partial \xi_i}$, where $\phi = (\phi_1, \ldots, \phi_r)$; for definiteness, let us take the domain of $\operatorname{div} \phi$ to be the set of points at which ϕ is differentiable (in the strict sense of 262Fa). Note that $\operatorname{div} \phi \in \mathcal{D}$ for every $\phi \in \mathcal{D}_r$. We need the following elementary facts.

(b) If $f : \mathbb{R}^r \to \mathbb{R}$ and $\phi : \mathbb{R}^r \to \mathbb{R}^r$ are functions, then $\operatorname{div}(f \times \phi) = \phi \boldsymbol{.} \operatorname{grad} f + f \times \operatorname{div} \phi$ at any point at which f and ϕ are both differentiable. (Use 473Bc-473Bd.)

(c) If $\phi : \mathbb{R}^r \to \mathbb{R}^r$ is a Lipschitz function with compact support, then $\int \operatorname{div} \phi \, d\mu = 0$. **P** $\operatorname{div} \phi$ is defined almost everywhere (by Rademacher's theorem, 262Q), measurable (473Be), bounded (473Cc) and with compact support, so

$$\int \operatorname{div} \phi \, d\mu = \sum_{i=1}^r \int \frac{\partial \phi_i}{\partial \xi_i} d\mu$$

is defined in $\mathbb{R}$. For each $i \leq r$, Fubini's theorem tells us that we can replace integration with respect to μ by a repeated integral, in which the inner integral is

$$\int_{-\infty}^{\infty} \frac{\partial \phi_i}{\partial \xi_i}(\xi_1, \ldots, \xi_r) d\xi_i = 0$$

because $\phi_i(\xi_1, \ldots, \xi_r) = 0$ whenever $|\xi_i|$ is large enough. So $\int \frac{\partial \phi_i}{\partial \xi_i} d\mu$ is also zero. Summing over i, we have the result. **Q**

(d) If $\phi : \mathbb{R}^r \to \mathbb{R}^r$ and $f : \mathbb{R}^r \to \mathbb{R}$ are Lipschitz functions, one of which has compact support, then

$$\int \phi \boldsymbol{.} \operatorname{grad} f \, d\mu + \int f \times \operatorname{div} \phi \, d\mu = 0.$$

P f and ϕ are both differentiable almost everywhere. So

$$\int \phi \boldsymbol{.} \operatorname{grad} f \, d\mu + \int f \times \operatorname{div} \phi \, d\mu = \int \operatorname{div}(f \times \phi) d\mu = 0$$

by (c) above. **Q**

(e) If $f \in \mathcal{L}^\infty(\mu)$, $g \in \mathcal{L}^1(\mu)$ is even (that is, $g(-x)$ is defined and equal to $g(x)$ for every $x \in \operatorname{dom} g$), and $\phi : \mathbb{R}^r \to \mathbb{R}^r$ is a Lipschitz function with compact support, then $\int (f * g) \times \operatorname{div} \phi = \int f \times \operatorname{div}(g * \phi)$, where $g * \phi = (g * \phi_1, \dots, g * \phi_r)$. **P** For each i,

$$\int (f * g) \times \frac{\partial \phi_i}{\partial \xi_i} d\mu = \iint f(x) g(y) \frac{\partial \phi_i}{\partial \xi_i}(x + y) \mu(dy) \mu(dx)$$

(255G/444Od)

$$= \iint f(x) g(-y) \frac{\partial \phi_i}{\partial \xi_i}(x + y) \mu(dy) \mu(dx)$$

(because g is even)

$$= \int f \times (g * \frac{\partial \phi_i}{\partial \xi_i}) d\mu = \int f \times \frac{\partial}{\partial \xi_i}(g * \phi_i) d\mu$$

by 473Dd. Now take the sum over i of both sides. **Q**

(f) If $g \in \mathcal{L}^1(\mu)$ and $\phi : \mathbb{R}^r \to \mathbb{R}^r$ is a bounded Lebesgue measurable function, then

$$\|(g * \phi)(x)\| \leq \|g\|_1 \sup_{y \in \mathbb{R}^r} \|\phi(y)\|$$

for every $x \in \mathbb{R}^r$. **P** We can find $z = (\zeta_1, \dots, \zeta_r) \in S_{r-1}$ such that

$$\|(g * \phi)(x)\| = (g * \phi)(x) \boldsymbol{.} z = \sum_{i=1}^r \int \zeta_i g(x - y) \phi_i(y) \mu(dy)$$

$$\leq \int |g(x - y)| \|\phi(y)\| \mu(dy) \leq \|g\|_1 \sup_{y \in \mathbb{R}^r} \|\phi(y)\|. \; \textbf{Q}$$

474C Invariance under isometries: Proposition Suppose that $T : \mathbb{R}^r \to \mathbb{R}^r$ is any isometry, and that ϕ is a function from a subset of $\mathbb{R}^r$ to $\mathbb{R}^r$. Then

$$\operatorname{div}(T^{-1} \phi T) = (\operatorname{div} \phi) T.$$

proof Set $z = T(\mathbf{0})$. By 4A4Jb, the isometry $x \mapsto Tx - z$ is linear and preserves inner products, so there is an orthogonal matrix S such that $T(x) = z + Sx$ for every $x \in \mathbb{R}^r$. Now suppose that $x \in \mathbb{R}^r$ is such that $(\operatorname{div} \phi)(Tx)$ is defined. Then $T(y) - T(x) - S(y - x) = 0$ for every y, so T is differentiable at x, with derivative S, and ϕT is differentiable at x, with derivative DS, where D is the derivative of ϕ at $T(x)$, by 473Bc. Also $T^{-1}(y) = S^{-1}(y - z)$ for every y, so T^{-1} is differentiable at $\phi(T(x))$ with derivative S^{-1}, and $T^{-1} \phi T$ is differentiable at x, with derivative $S^{-1} DS$. Now if D is $\langle \delta_{ij} \rangle_{1 \leq i,j \leq r}$ and S is $\langle \sigma_{ij} \rangle_{1 \leq i,j \leq r}$ and $S^{-1} DS$ is $\langle \tau_{ij} \rangle_{1 \leq i,j \leq r}$, then S^{-1} is the transpose $\langle \sigma_{ji} \rangle_{1 \leq i,j \leq r}$ of S, because S is orthogonal, so

$$\operatorname{div}(T^{-1} \phi T)(x) = \sum_{i=1}^r \tau_{ii} = \sum_{i=1}^r \sum_{j=1}^r \sigma_{ji} \sum_{k=1}^r \delta_{jk} \sigma_{ki}$$

$$= \sum_{j=1}^r \sum_{k=1}^r \delta_{jk} \sum_{i=1}^r \sigma_{ji} \sigma_{ki} = \sum_{j=1}^r \delta_{jj} = \operatorname{div} \phi(x)$$

because $\sum_{i=1}^r \sigma_{ji} \sigma_{jk} = 1$ if $j = k$ and 0 otherwise. If $\operatorname{div}(T^{-1} \phi T)(x)$ is defined, then (because T^{-1} is also an isometry)

$$(\operatorname{div}\phi)(Tx) = \operatorname{div}(TT^{-1}\phi TT^{-1})(Tx) = \operatorname{div}(T^{-1}\phi T)(T^{-1}Tx) = \operatorname{div}(T^{-1}\phi T)(x).$$

So the functions $\operatorname{div}(T^{-1}\phi T)$ and $(\operatorname{div}\phi)T$ are identical.

474D Locally finite perimeter: Definition Let $E \subseteq \mathbb{R}^r$ be a Lebesgue measurable set. Its **perimeter** per E is

$$\sup\{|\textstyle\int_E \operatorname{div}\phi\, d\mu| : \phi : \mathbb{R}^r \to B(\mathbf{0},1) \text{ is a Lipschitz function with compact support}\}.$$

E has **locally finite perimeter** if

$$\sup\{|\textstyle\int_E \operatorname{div}\phi\, d\mu| : \phi : \mathbb{R}^r \to \mathbb{R}^r \text{ is a Lipschitz function, } \|\phi\| \leq \chi B(\mathbf{0},n)\}$$

is finite for every $n \in \mathbb{N}$.

474E Theorem Suppose that $E \subseteq \mathbb{R}^r$ has locally finite perimeter.

(i) There are a Radon measure λ_E^∂ on $\mathbb{R}^r$ and a function $\psi : \mathbb{R}^r \to S_{r-1}$ such that

$$\textstyle\int_E \operatorname{div}\phi\, d\mu = \int \phi \bullet \psi\, d\lambda_E^\partial$$

for every Lipschitz function $\phi : \mathbb{R}^r \to \mathbb{R}^r$ with compact support.

(ii) This formula uniquely determines λ_E^∂, which can also be defined by saying that

$$\lambda_E^\partial(G) = \sup\{|\textstyle\int_E \operatorname{div}\phi\, d\mu| : \phi : \mathbb{R}^r \to \mathbb{R}^r \text{ is Lipschitz, } \|\phi\| \leq \chi G\}$$

whenever $G \subseteq \mathbb{R}^r$ is open.

(iii) If $\hat\psi$ is another function satisfying the formula in (i), then $\hat\psi = \psi$ λ_E^∂-almost everywhere.

proof (a) For each $l \in \mathbb{N}$, set

$$\gamma_l = \sup\{|\textstyle\int_E \operatorname{div}\phi\, d\mu| : \phi : \mathbb{R}^r \to \mathbb{R}^r \text{ is Lipschitz, } \|\phi\| \leq \chi B(\mathbf{0},l)\}.$$

Write C_k for the space of continuous functions with compact support from $\mathbb{R}^r$ to $\mathbb{R}$. By 473Dc and 473De, $f * \tilde h_n \in \mathcal{D}$ for every $f \in C_k$, $n \in \mathbb{N}$. Now the point is that

$$L_i(f) = -\lim_{n\to\infty} \textstyle\int_E \frac{\partial}{\partial\xi_i}(f * \tilde h_n)d\mu$$

is defined for every $f \in C_k$, $i \leq r$. **P** Applying 473Ed, we see that $\|f - f * \tilde h_n\|_\infty \to 0$ as $n \to \infty$. But this means that $\|(f * \tilde h_m) - (f * \tilde h_n)\|_\infty \to 0$ as $m, n \to \infty$. Set $\phi^{(n)}(x) = (f * \tilde h_n)(x)e_i$, where e_i is the unit vector $(0,\dots,1,\dots,0)$ with a 1 in the ith place. We have some $l \in \mathbb{N}$ such that $|f| \leq l\chi B(\mathbf{0},l)$; in which case $\phi^{(n)}(x) = \mathbf{0}$ whenever $\|x\| > l+1$ and $n \in \mathbb{N}$. This means that

$$\begin{aligned}|\textstyle\int_E \frac{\partial}{\partial\xi_i}(f * \tilde h_m)d\mu - \int_E \frac{\partial}{\partial\xi_i}(f * \tilde h_n)d\mu| &= |\textstyle\int \operatorname{div}(\phi^{(m)} - \phi^{(n)})d\mu| \\ &\leq \gamma_{l+1} \sup_{x\in\mathbb{R}^r} \|\phi^{(m)}(x) - \phi^{(n)}(x)\| \\ &\text{(applying the definition of } \gamma_{l+1} \text{ to a suitable multiple of } \phi^{(m)} - \phi^{(n)}) \\ &= \gamma_{l+1}\|(f * \tilde h_m) - (f * \tilde h_n)\|_\infty \to 0\end{aligned}$$

as $m, n \to \infty$. Thus $\langle \int_E \frac{\partial}{\partial\xi_i}(f * \tilde h_n)d\mu\rangle_{n\in\mathbb{N}}$ is a Cauchy sequence and must have a limit. **Q**

If f is Lipschitz, then $\lim_{n\to\infty} \|f - f * \tilde h_n\|_\infty = 0$ and $|f - f * \tilde h_n| \leq \|f - f * \tilde h_n\|_\infty \chi B(\mathbf{0}, l+1)$ for every n, so $\lim_{n\to\infty} \int_E \frac{\partial}{\partial\xi_i}(f - f * \tilde h_n)d\mu = 0$, and $L_i(f) = -\int_E \frac{\partial f}{\partial\xi_i}d\mu$.

Note that the argument shows also that $|L_i(f)| \leq \gamma_{l+1}\|f\|_\infty$ if $f(x) = 0$ for $x \in \mathbb{R}^r \setminus B(\mathbf{0},l)$.

(b) Because all the functionals $f \mapsto \int_E \frac{\partial}{\partial\xi_i}(f * \tilde h_n)d\mu$ are linear, L_i is linear. Moroever, by the last remark in (a), it is order-bounded when regarded as a linear functional on the Riesz space C_k, so is expressible as a difference $L_i^+ - L_i^-$ of positive linear functionals (356B).

By the Riesz Representation Theorem (436J), we have Radon measures λ_i^+, λ_i^- on $\mathbb{R}^r$ such that $L_i^+(f) = \int f d\lambda_i^+$, $L_i^-(f) = \int f d\lambda_i^-$ for every $f \in C_k$. If we set $L = \sum_{i=1}^r L_i^+ + L_i^-$, there is another Radon measure $\tilde{\lambda}$ on $\mathbb{R}^r$ such that $L(f) = \int f d\tilde{\lambda}$ for every $f \in C_k$. Now each λ_i^+, λ_i^- is an indefinite-integral measure with respect to $\tilde{\lambda}$. **P** Because all these measures are σ-finite and the completions of their restrictions to the Borel σ-algebra, 234G tells us that it is enough to check that $\lambda_i^+(F) = \lambda_i^-(F) = 0$ whenever $\tilde{\lambda}F = 0$. But this is immediate from 416E(a-v). **Q**

For each $i \leq r$, let g_i^+, g_i^- be Radon-Nikodým derivatives of λ_i^+, λ_i^- with respect to $\tilde{\lambda}$. Adjusting them on a $\tilde{\lambda}$-negligible set if necessary, we may suppose that they are all bounded non-negative Borel measurable functions from $\mathbb{R}^r$ to $\mathbb{R}$. (Recall from 256C that $\tilde{\lambda}$ must be the completion of its restriction to the Borel σ-algebra.) Set $g_i = g_i^+ - g_i^-$ for each i. Then

$$\begin{aligned} -\int_E \frac{\partial f}{\partial \xi_i} d\mu &= L_i^+(f) - L_i^-(f) = \int f d\lambda_i^+ - \int f d\lambda_i^- \\ &= \int f \times g_i^+ d\tilde{\lambda} - \int f \times g_i^- d\tilde{\lambda} = \int f \times g_i d\tilde{\lambda} \end{aligned}$$

for every Lipschitz function f with compact support (235M). Set $g = \sqrt{\sum_{i=1}^r g_i^2}$. For $i \leq r$, set $\psi_i(x) = -\frac{g_i(x)}{g(x)}$ when $g(x) \neq 0$, $\frac{1}{\sqrt{r}}$ when $g(x) = 0$, so that $\psi = (\psi_1, \dots, \psi_r) : \mathbb{R}^r \to S_{r-1}$ is Borel measurable. Let λ_E^∂ be the indefinite-integral measure over $\tilde{\lambda}$ defined by g; then λ_E^∂ is a Radon measure on $\mathbb{R}^r$ (256E/416S).

(c) Now take any Lipschitz function $\phi : \mathbb{R}^r \to \mathbb{R}^r$ with compact support. Express it as $(\phi_1, \dots, \phi_r)$ where $\phi_i : \mathbb{R}^r \to \mathbb{R}$ is a Lipschitz function with compact support for each i. Then

$$\begin{aligned} \int_E \operatorname{div} \phi \, d\mu &= \sum_{i=1}^r \int_E \frac{\partial \phi_i}{\partial \xi_i} d\mu = -\sum_{i=1}^r L_i(\phi_i) \\ &= -\sum_{i=1}^r L_i^+(\phi_i) + \sum_{i=1}^r L_i^-(\phi_i) = -\sum_{i=1}^r \int \phi_i d\tilde{\lambda}_i^+ + \sum_{i=1}^r \int \phi_i d\tilde{\lambda}_i^- \\ &= -\sum_{i=1}^r \int \phi_i \times g_i^+ d\tilde{\lambda} + \sum_{i=1}^r \int \phi_i \times g_i^- d\tilde{\lambda} \end{aligned}$$

(by 235M)

$$= -\sum_{i=1}^r \int \phi_i \times g_i d\tilde{\lambda} = \sum_{i=1}^r \int \phi_i \times \psi_i d\lambda_E^\partial$$

(by 235M again, because $\psi_i \times g = -g_i$)

$$= \int \phi \boldsymbol{.} \psi \, d\lambda_E^\partial.$$

So we have λ_E^∂ and ψ satisfying (i).

(d) Now suppose that $G \subseteq \mathbb{R}^r$ is open. If $\phi : \mathbb{R}^r \to \mathbb{R}^r$ is a Lipschitz function with compact support and $\|\phi\| \leq \chi G$, then

$$|\textstyle\int_E \operatorname{div} \phi \, d\mu| = |\int \phi \boldsymbol{.} \psi \, d\lambda_E^\partial| \leq \int \|\phi\| d\lambda_E^\partial \leq \lambda_E^\partial(G).$$

On the other hand, if $\gamma < \lambda_E^\partial(G)$, let $G_0 \subseteq G$ be a bounded open set such that $\gamma < \lambda_E^\partial(G_0)$, and set $\epsilon = \frac{1}{2}(\lambda_E^\partial(G_0) - \gamma)$. Let $K \subseteq G_0$ be a compact set such that $\lambda_E^\partial(G_0 \setminus K) \leq \epsilon$. Let $\delta > 0$ be such that $\|x - y\| \geq 2\delta$ whenever $y \in K$ and $x \in \mathbb{R}^r \setminus G_0$, and set $H = \{x : \inf_{y \in K} \|x - y\| < \delta\}$. Now there are $f_1, \dots, f_r \in C_k$ such that

$$\textstyle\sum_{i=1}^r f_i^2 \leq \chi H, \quad \int \sum_{i=1}^r f_i \times \psi_i d\lambda_E^\partial \geq \gamma.$$

P For each $i \leq r$, we can find a sequence $\langle g_{mi} \rangle_{m \in \mathbb{N}}$ in C_k such that $\int |g_{mi} - (\psi_i \times \chi K)| d\lambda_E^\partial \leq 2^{-m}$ for every $m \in \mathbb{N}$ (416I); multiplying the g_{mi} by a function which takes the value 1 on K and 0 outside H if necessary, we can suppose that $g_{mi}(x) = 0$ for $x \notin H$. Set

$$f_{mi} = \frac{g_{mi}}{\max(1, \sqrt{\sum_{j=1}^r g_{mj}^2})} \in C_k$$

for each m and i. Now $\lim_{m\to\infty} f_{mi}(x) = \psi_i(x)$ for every $i \le r$ whenever $\lim_{m\to\infty} g_{mi}(x) = \psi_i(x)$ for every $i \le r$, which is the case for λ_E^∂-almost every $x \in K$. Also $\sum_{i=1}^r f_{mi}^2 \le \chi H$ for every m, so $|\sum_{i=1}^r f_{mi} \times \psi_i| \le \chi H$ for every m, while

$$\lim_{m\to\infty} \sum_{i=1}^r \int_K f_{mi} \times \psi_i d\lambda_E^\partial = \sum_{i=1}^r \int_K \psi_i^2 d\lambda_E^\partial = \lambda_E^\partial(K).$$

At the same time,

$$|\sum_{i=1}^r \int_{\mathbb{R}^r \setminus K} f_{mi} \times \psi_i d\lambda_E^\partial| \le \lambda_E^\partial(H \setminus K) \le \epsilon$$

for every m, so

$$\sum_{i=1}^r \int f_{mi} \times \psi_i d\lambda_E^\partial \ge \lambda_E^\partial(G_0) - 2\epsilon = \gamma$$

for all m large enough, and we may take $f_i = f_{mi}$ for such an m. **Q**

Now, for $n \in \mathbb{N}$, set

$$\phi_n = (f_1 * \tilde{h}_n, \dots, f_r * \tilde{h}_n) \in \mathcal{D}_r.$$

For all n large enough, we shall have $\|x - y\| \ge \frac{1}{n+1}$ for every $x \in \mathbb{R}^r \setminus G_0$ and $y \in H$, so that $\phi_n(x) = 0$ if $x \notin G_0$. By 473Dg,

$$\|\phi_n(x)\| \le \sup_{y\in\mathbb{R}} \sqrt{\sum_{i=1}^r f_i(y)^2} \le 1$$

for every x and n, so that $\|\phi_n\| \le \chi G_0$ for all n large enough. Next, $\phi_n(x) \to (f_1(x), \dots, f_r(x))$ for every $x \in \mathbb{R}^r$ (473Ed), so

$$\int_E \operatorname{div} \phi_n d\mu = \int \phi_n \bullet \psi \, d\lambda_E^\partial \to \int \sum_{i=1}^r f_i \times \psi_i d\lambda_E^\partial \ge \gamma$$

as $n \to \infty$, by Lebesgue's Dominated Convergence Theorem. As γ is arbitrary,

$$\sup\{\int_E \operatorname{div} \phi \, d\mu : \phi \in \mathcal{D}_r, \, \|\phi\| \le \chi G\} \ge \lambda_E^\partial(G),$$

and the two must be equal.

(e) Thus λ_E^∂ must satisfy (ii). By 416Eb, it is uniquely defined. Now suppose that $\hat{\psi}$ is another function from a λ_E^∂-conegligible set to $\mathbb{R}^r$ and satisfies (i). Then

$$\int \phi \bullet \psi \, d\lambda_E^\partial = \int \phi \bullet \hat{\psi} \, d\lambda_E^\partial$$

for every Lipschitz function $\phi : \mathbb{R}^r \to \mathbb{R}^r$ with compact support. Take any $i \le r$ and any compact set $K \subseteq \mathbb{R}^r$. For $m \in \mathbb{N}$, set $f_m(x) = \max(0, 1 - 2^m \inf_{y\in K} \|y - x\|)$ for $x \in \mathbb{R}^r$, so that $\langle f_m \rangle_{m\in\mathbb{N}}$ is a sequence of Lipschitz functions with compact support and $\lim_{m\to\infty} f_m = \chi K$. Set

$$\phi_m = (0, \dots, f_m, \dots, 0),$$

where the non-zero term is in the ith position. Then

$$\begin{aligned}\int_K \psi_i d\lambda_E^\partial &= \lim_{m\to\infty} \int f_m \times \psi_i d\lambda_E^\partial = \lim_{m\to\infty} \int \phi_m \bullet \psi \, d\lambda_E^\partial \\ &= \lim_{m\to\infty} \int \phi_m \bullet \hat{\psi} \, d\lambda_E^\partial = \int_K \hat{\psi}_i d\lambda_E^\partial.\end{aligned}$$

By the Monotone Class Theorem (136B), or otherwise, $\int_F \hat{\psi}_i d\lambda_E^\partial = \int_F \psi_i d\lambda_E^\partial$ for every bounded Borel set F, so that $\hat{\psi}_i = \psi_i$ λ_E^∂-a.e.; as i is arbitrary, $\psi = \hat{\psi}$ λ_E^∂-a.e. This completes the proof.

474F Definitions In the context of 474E, I will call λ_E^∂ the **perimeter measure** of E, and if ψ is a function from a λ_E^∂-conegligible subset of $\mathbb{R}^r$ to S_{r-1} which has the property in (i) of the theorem, I will call it an **outward-normal** function for E.

The words 'perimeter' and 'outward normal' are intended to suggest geometric interpretations; much of this section and the next will be devoted to validating this suggestion.

Observe that if E has locally finite perimeter, then $\operatorname{per} E = \lambda_E^\partial(\mathbb{R}^r)$.

474G The reduced boundary Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter; let λ_E^∂ be its perimeter measure and ψ an outward-normal function for E. The **reduced boundary** $\partial^\$ E$ is the set of those $y \in \mathbb{R}^r$ such that, for some $z \in S_{r-1}$,

$$\lim_{\delta \downarrow 0} \frac{1}{\lambda_E^\partial B(y,\delta)} \int_{B(y,\delta)} \|\psi(x) - z\| \, d\lambda_E^\partial = 0.$$

(When requiring that the limit be defined, I mean to insist that $\lambda_E^\partial B(y,\delta)$ should be non-zero for every $\delta > 0$, that is, that y belongs to the support of $\partial\lambda_E^\$$. **Warning!** Some authors use the phrase 'reduced boundary' for a slightly larger set.) Note that, writing $\psi = (\psi_1, \dots, \psi_r)$ and $z = (\zeta_1, \dots, \zeta_r)$, we must have

$$\zeta_i = \lim_{\delta \downarrow 0} \frac{1}{\lambda_E^\partial B(y,\delta)} \int_{B(y,\delta)} \psi_i d\lambda_E^\partial,$$

so that z is uniquely defined; call it $\psi_E(y)$. Of course $\partial^\$ E$ and ψ_E are determined entirely by the set E, because λ_E^∂ is uniquely determined and ψ is determined up to a λ_E^∂-negligible set (474E).

By Besicovitch's Density Theorem (472D),

$$\lim_{\delta \downarrow 0} \frac{1}{\lambda_E^\partial B(x,\delta)} \int_{B(x,\delta)} |\psi_i(x) - \psi_i(y)| \lambda_E^\partial(dx) = 0$$

for λ_E^∂-almost every $y \in \mathbb{R}^r$, for every $i \le r$; and for any such y, $\psi_E(y)$ is defined and equal to $\psi(y)$. Thus $\partial^\$ E$ is λ_E^∂-conegligible and ψ_E is an outward-normal function for E. I will call $\psi_E : \partial^\$ E \to S_{r-1}$ the **canonical outward-normal function** of E.

474H Invariance under isometries: Proposition Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter. Let λ_E^∂ be its perimeter measure, and ψ an outward normal function for E. If $T : \mathbb{R}^r \to \mathbb{R}^r$ is any isometry, then $T[E]$ has locally finite perimeter, $\lambda_{T[E]}^\partial$ is the image measure $\lambda_E^\partial T^{-1}$, and $S\psi T^{-1}$ is an outward normal function for $T[E]$, where S is the derivative of T.

proof (a) As noted in 474C, the derivative of T is constant, and is an orthogonal matrix. Suppose that $n \in \mathbb{N}$. Let $\phi : \mathbb{R}^r \to \mathbb{R}^r$ be a Lipschitz function such that $\|\phi\| \le \chi B(\mathbf{0}, n)$. Then

$$\left| \int_{T[E]} \operatorname{div} \phi \, d\mu \right| = \left| \int_E (\operatorname{div} \phi) T \, d\mu \right|$$

(263D, because $|\det S| = 1$)

$$= \left| \int_E \operatorname{div}(T^{-1}\phi T) d\mu \right|$$

(474C)

$$= \left| \int_E \operatorname{div}(S^{-1}\phi T) d\mu \right|$$

(because $S^{-1}\phi T$ and $T^{-1}\phi T$ differ by a constant, and must have the same derivative)

$$\le \lambda_E^\partial(T^{-1}[B(\mathbf{0}, n)])$$

because $S^{-1}\phi T$ is a Lipschitz function and

$$\|S^{-1}\phi T\| = \|\phi T\| \le \chi T^{-1}[B(\mathbf{0}, n)].$$

Since $T^{-1}[B(\mathbf{0}, n)]$ is bounded, $\lambda_E^\partial(T^{-1}[B(\mathbf{0}, n)])$ is finite for every n, and $T[E]$ has locally finite perimeter.

(b) We can therefore speak of its perimeter measure $\lambda_{T[E]}^\partial$. Let $G \subseteq \mathbb{R}^r$ be an open set. If $\phi : \mathbb{R}^r \to \mathbb{R}^r$ is a Lipschitz function and $\|\phi\| \le \chi T[G]$, then

$$\left| \int_{T[E]} \operatorname{div} \phi \, d\mu \right| = \left| \int_E \operatorname{div}(S^{-1}\phi T) d\mu \right| \le \lambda_E^\partial(G)$$

because $S^{-1}\phi T$ is a Lipschitz function dominated by χG. As ϕ is arbitrary, $\lambda_{T[E]}^\partial(T[G]) \le \lambda_E^\partial(G)$. Applying the same argument in reverse, with T^{-1} in the place of T, we see that $\lambda_E^\partial(G) \le \lambda_{T[E]}^\partial(T[G])$, so the two are

equal. Now this means that the Radon measures $\lambda^\partial_{T[E]}$ and $\lambda^\partial_E T^{-1}$ (418I) agree on open sets, and must be identical (416Eb).

(c) Now consider $S\psi T^{-1}$. Since ψ is defined λ^∂_E-almost everywhere and takes values in S_{r-1}, ψT and $S\psi T^{-1}$ are defined $\lambda^\partial_{T[E]}$-almost everywhere and take values in S_{r-1}. If $\phi : \mathbb{R}^r \to \mathbb{R}^r$ is a Lipschitz function with compact support,

$$\begin{aligned}\int_{T[E]} \operatorname{div}\phi\, d\mu &= \int_E (\operatorname{div}\phi)T\, d\mu = \int_E \operatorname{div}(T^{-1}\phi T)d\mu \\ &= \int_E \operatorname{div}(S^{-1}\phi T)d\mu = \int (S^{-1}\phi T)\boldsymbol{.}\psi\, d\lambda^\partial_E \\ &= \int (\phi T)\boldsymbol{.}(S\psi)d\lambda^\partial_E\end{aligned}$$

(because S is orthogonal)

$$= \int \phi\boldsymbol{.}(S\psi T^{-1})d(\lambda^\partial_E T^{-1})$$

(235I)

$$= \int \phi\boldsymbol{.}(S\psi T^{-1})d\lambda^\partial_{T[E]}$$

Accordingly $S\psi T^{-1}$ is an outward-normal function for $T[E]$.

474I Half-spaces It will be useful, and perhaps instructive, to check the most elementary special case.

Proposition Let $H \subseteq \mathbb{R}^r$ be a half-space $\{x : x\boldsymbol{.}v \leq \alpha\}$, where $v \in S^{r-1}$. Then H has locally finite perimeter; its perimeter measure λ^∂_H is defined by saying

$$\lambda^\partial_H(F) = \nu(F \cap \partial H)$$

whenever $F \subseteq \mathbb{R}^r$ is such that ν measures $F \cap \partial H$, and the constant function with value v is an outward-normal function for H.

proof (a) Suppose, to begin with, that v is the unit vector $(0, \dots, 1)$ and that $\alpha = 0$, so that $H = \{x : \xi_r \leq 0\}$. Let $\phi : \mathbb{R}^r \to \mathbb{R}^r$ be a Lipschitz function with compact support. Then for any $i < r$

$$\int_H \frac{\partial \phi_i}{\partial \xi_i}\mu(dx) = 0$$

because we can regard this as a multiple integral in which the inner integral is with respect to ξ_i and is therefore always zero. On the other hand, integrating with respect to the rth coordinate first,

$$\begin{aligned}\int_H \frac{\partial \phi_r}{\partial \xi_r}\mu(dx) &= \int_{\mathbb{R}^{r-1}} \int_{-\infty}^0 \frac{\partial \phi_r}{\partial \xi_r}(z,t)dt\, \mu_{r-1}(dz) \\ &= \int_{\mathbb{R}^{r-1}} \phi_r(z,0)\mu_{r-1}(dz) = \int_{\partial H} \phi_r(x)\nu(dx)\end{aligned}$$

(identifying ν on $\mathbb{R}^{r-1} \times \{0\}$ with μ_{r-1} on $\mathbb{R}^{r-1}$)

$$= \int_{\partial H} \phi\boldsymbol{.}v\, d\nu = \int \phi\boldsymbol{.}v\, d\lambda$$

where λ is the indefinite-integral measure over ν defined by the function $\chi(\partial H)$. Note that (by 234Da) λ can also be regarded as $\nu_{\partial H}\iota^{-1}$, where $\nu_{\partial H}$ is the subspace measure on ∂H and $\iota : \partial H \to \mathbb{R}^r$ is the identity map. Now $\nu_{\partial H}$ can be identified with Lebesgue measure on $\mathbb{R}^{r-1}$, by 265B or otherwise, so in particular is a Radon measure, and λ also is a Radon measure, by 418I or otherwise.

This means that λ and the constant function with value v satisfy the conditions of 474E, and must be the perimeter measure of H and an outward-normal function.

(b) For the general case, let S be an orthogonal matrix such that $S(0,\dots,1) = v$, and set $T(x) = Sx + \alpha v$ for every x, so that $H = T[\{x : \xi_r \leq 0\}]$. By 474H, the perimeter measure of H is λT^{-1} and the constant function with value v is an outward-normal function for H. Now the Radon measure $\lambda_H^\partial = \lambda T^{-1}$ is defined by saying that

$$\lambda_H^\partial F = \lambda T^{-1}[F] = \nu(T^{-1}[F] \cap \{x : \xi_r = 0\}) = \nu(F \cap T[\{x : \xi_r = 0\}]) = \nu(F \cap \partial H)$$

whenever $\nu(F \cap \partial H)$ is defined, because ν (being a scalar multiple of a Hausdorff measure) must be invariant under the isometry T.

474J Lemma Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter. Let λ_E^∂ be the perimeter measure of E, and ψ_E its canonical outward-normal function. Then $\mathbb{R}^r \setminus E$ also has locally finite perimeter; its perimeter measure is λ_E^∂, its reduced boundary is $\partial^\$ E$, and its canonical outward-normal function is $-\psi_E$.

proof By 474Bc,

$$\int_{\mathbb{R}^r \setminus E} \operatorname{div} \phi \, d\mu = -\int_E \operatorname{div} \phi \, d\mu = \int \phi \boldsymbol{.} (-\psi_E) \, d\lambda_E^\partial$$

for every Lipschitz function $\phi : \mathbb{R}^r \to \mathbb{R}^r$ with compact support. The uniqueness assertions in 474E tell us that $\mathbb{R}^r \setminus E$ has locally finite perimeter, that its perimeter measure is λ_E^∂, and that $-\psi_E$ is an outward-normal function for $\mathbb{R}^r \setminus E$. Referring to the definition of 'reduced boundary' in 474G, we see at once that $\partial^\$(\mathbb{R}^r \setminus E) = \partial^\$ E$ and that $\psi_{\mathbb{R}^r \setminus E} = -\psi_E$.

474K Lemma Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter; let λ_E^∂ be its perimeter measure, and ψ an outward-normal function for E. Let $\phi : \mathbb{R}^r \to \mathbb{R}^r$ be a Lipschitz function with compact support, and $g \in \mathcal{D}$ an even function. Then

$$\int \phi \boldsymbol{.} \operatorname{grad}(g * \chi E) d\mu + \int (g * \phi) \boldsymbol{.} \psi \, d\lambda_E^\partial = 0.$$

proof

$$\int \phi \boldsymbol{.} \operatorname{grad}(g * \chi E) d\mu = -\int (g * \chi E) \times \operatorname{div} \phi \, d\mu$$

(474Bd, using 473Df to see that $g * \chi E$ is Lipschitz)

$$= -\int \chi E \times \operatorname{div}(g * \phi) d\mu$$

(474Be)

$$= -\int (g * \phi) \boldsymbol{.} \psi \, d\lambda_E^\partial$$

(because $g * \phi$ is smooth and has compact support, so is Lipschitz), as required.

474L Two isoperimetric inequalities: Theorem Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter, and λ_E^∂ its perimeter measure.

(a) If E is bounded, then $(\mu E)^{(r-1)/r} \leq \operatorname{per} E$.

(b) If $B \subseteq \mathbb{R}^r$ is a closed ball, then

$$\min(\mu(B \cap E), \mu(B \setminus E))^{(r-1)/r} \leq 2c\lambda_E^\partial(\operatorname{int} B),$$

where $c = 2^{r+2}(1 + \sqrt{r})(1 + 2^{r+1})$.

proof (a) Let $\epsilon > 0$. By 473Ef, there is an $n \in \mathbb{N}$ such that $\|f - \chi E\|_{r/(r-1)} \leq \epsilon$, where $f = \chi E * \tilde{h}_n$. Note that f is smooth (473De) and has compact support, because E is bounded. Let $\eta > 0$ be such that

$$\int \|\operatorname{grad} f\| d\mu \leq \int \frac{\|\operatorname{grad} f\|^2}{\sqrt{\eta + \|\operatorname{grad} f\|^2}} \, d\mu + \epsilon,$$

and set $\phi = \frac{\operatorname{grad} f}{\sqrt{\eta + \|\operatorname{grad} f\|^2}}$. Then $\phi \in \mathcal{D}_r$ and $\|\phi(x)\| \leq 1$ for every $x \in \mathbb{R}^r$. Now we can estimate

$$\begin{aligned}\int \|\operatorname{grad} f\| d\mu &\leq \int \phi \boldsymbol{.} \operatorname{grad} f \, d\mu + \epsilon \\ &= -\int (\tilde{h}_n * \phi) \boldsymbol{.} \psi \, d\lambda_E^\partial + \epsilon\end{aligned}$$

(where ψ is an outward-normal function for E, by 474K)

$$\leq \int \|\tilde{h}_n * \phi\| d\lambda_E^\partial + \epsilon \leq \operatorname{per} E + \epsilon$$

because $\|(\tilde{h}_n * \phi)(x)\| \leq 1$ for every $x \in \mathbb{R}^r$, by 473Dg. Accordingly

$$(\mu E)^{(r-1)/r} = \|\chi E\|_{r/(r-1)} \leq \|f\|_{r/(r-1)} + \epsilon \leq \int \|\operatorname{grad} f\| d\mu + \epsilon$$

(473H)

$$\leq \operatorname{per} E + 2\epsilon.$$

As ϵ is arbitrary, we have the result.

(b)(i) Set $\alpha = \min(\mu(B \cap E), \mu(B \setminus E))$. If $\alpha = 0$, the result is trivial; so suppose that $\alpha > 0$. Take any $\epsilon \in]0, \alpha]$. Let B_1 be a closed ball, with the same centre as B and strictly smaller non-zero radius, such that $\mu(B \setminus B_1) \leq \epsilon$; then $\alpha - \epsilon \leq \min(\mu(B_1 \cap E), \mu(B_1 \setminus E))$. For $f \in \mathcal{L}^{r/(r-1)}(\mu)$ set

$$\gamma_0(f) = \frac{1}{\mu B_1} \int_{B_1} f d\mu, \quad \gamma_1(f) = \|(f \times \chi B_1) - \gamma_0(f) \chi B_1\|_{r/(r-1)};$$

then both γ_0 and γ_1 are continuous functions on $\mathcal{L}^{r/(r-1)}(\mu)$ if we give it its usual pseudometric $(f, g) \mapsto \|f - g\|_{r/(r-1)}$. Now $\gamma_1(\chi(E \cap B)) \geq \frac{1}{2}(\alpha - \epsilon)^{(r-1)/r}$. **P** We have

$$\gamma_0(\chi(E \cap B)) = \tfrac{\mu(B_1 \cap E)}{\mu B_1},$$

$$\begin{aligned}\gamma_1(\chi(E \cap B))^{r/(r-1)} &= \int_{B_1} |\chi(E \cap B) - \gamma_0(\chi(E \cap B))|^{r/(r-1)} \\ &= \mu(B_1 \cap E)\big(1 - \tfrac{\mu(B_1 \cap E)}{\mu B_1}\big)^{r/(r-1)} + \mu(B_1 \setminus E)\big(\tfrac{\mu(B_1 \cap E)}{\mu B_1}\big)^{r/(r-1)} \\ &= \mu(B_1 \cap E)\big(\tfrac{\mu(B_1 \setminus E)}{\mu B_1}\big)^{r/(r-1)} + \mu(B_1 \setminus E)\big(\tfrac{\mu(B_1 \cap E)}{\mu B_1}\big)^{r/(r-1)}.\end{aligned}$$

Either $\mu(B_1 \cap E) \geq \frac{1}{2}\mu B_1$ or $\mu(B_1 \setminus E) \geq \frac{1}{2}\mu B_1$; suppose the former. Then

$$\gamma_1(\chi(E \cap B))^{r/(r-1)} \geq \frac{1}{2^{r/(r-1)}} \mu(B_1 \setminus E) \geq \frac{1}{2^{r/(r-1)}}(\alpha - \epsilon)$$

and $\gamma_1(\chi(E \cap B)) \geq \frac{1}{2}(\alpha - \epsilon)^{r/(r-1)}$. Exchanging $B_1 \cap E$ and $B_1 \setminus E$ we have the same result if $\mu(B_1 \cap E) \geq \frac{1}{2}\mu B_1$. **Q**

(ii) Express B as $B(y, \delta)$ and B_1 as $B(y, \delta_1)$. Take $n_0 \geq \frac{2}{\delta - \delta_1}$. Because γ_1 is $\| \|_{r/(r-1)}$-continuous, there is an $n \geq n_0$ such that $\gamma_1(f) \geq \frac{1}{2}(\alpha - \epsilon)^{(r-1)/r} - \epsilon$, where $f = \tilde{h}_n * \chi(E \cap B)$ (473Ef); as in part (a) of the proof, $f \in \mathcal{D}$. Let $\eta > 0$ be such that

$$\int_{B_1} \frac{\|\operatorname{grad} f\|^2}{\sqrt{\eta + \|\operatorname{grad} f\|^2}} d\mu \geq \int_{B_1} \|\operatorname{grad} f\| d\mu - \epsilon.$$

Let $m \geq n_0$ be such that $\int \phi \boldsymbol{.} \operatorname{grad} f \, d\mu \geq \int_{B_1} \|\operatorname{grad} f\| d\mu - 2\epsilon$, where

$$\phi = \tilde{h}_m * \big(\frac{\operatorname{grad} f}{\sqrt{\eta + \|\operatorname{grad} f\|^2}} \times \chi B_1\big).$$

Note that $\phi(x) = 0$ if $\|x - y\| \geq \frac{1}{2}(\delta + \delta_1)$, so that $(\tilde{h}_n * \phi)(x) = 0$ if $x \notin \operatorname{int} B$. By 473Dg, $\|\phi(x)\| \leq 1$ for every x and $\|(\tilde{h}_n * \phi)(x)\| \leq 1$ for every x, so $\|\tilde{h}_n * \phi\| \leq \chi(\operatorname{int} B)$.

Now we have

$$\begin{aligned}\int \phi \boldsymbol{.} \operatorname{grad} f \, d\mu &= \int \phi \boldsymbol{.} \operatorname{grad}(\tilde{h}_n * \chi(E \cap B)) \, d\mu \\ &= -\int (\tilde{h}_n * \chi(E \cap B)) \times \operatorname{div} \phi \, d\mu \end{aligned}$$

(474Bd)

$$= -\int_{E \cap B} \operatorname{div}(\tilde{h}_n * \phi) d\mu$$

(474Be)

$$= -\int_E \operatorname{div}(\tilde{h}_n * \phi) d\mu \leq \lambda_E^{\partial}(\operatorname{int} B)$$

(474E).

(iii) Accordingly

$$\frac{1}{2}(\alpha - \epsilon)^{(r-1)/r} - \epsilon \leq \gamma_1(f) \leq c \int_{B_1} \| \operatorname{grad} f \| d\mu$$

(473K)

$$\leq c\Big(\int \phi \boldsymbol{.} \operatorname{grad} f \, d\mu + 2\epsilon \Big) \leq c(\lambda_E^{\partial}(\operatorname{int} B) + 2\epsilon).$$

As ϵ is arbitrary, $\alpha^{(r-1)/r} \leq 2c\lambda_E^{\partial}(\operatorname{int} B)$, as claimed.

474M Lemma Suppose that $E \subseteq \mathbb{R}^r$ has locally finite perimeter, with perimeter measure λ_E^{∂} and an outward-normal function ψ. Then for any $y \in \mathbb{R}^r$ and any Lipschitz function $\phi : \mathbb{R}^r \to \mathbb{R}^r$,

$$\int_{E \cap B(y,\delta)} \operatorname{div} \phi \, d\mu = \int_{B(y,\delta)} \phi \boldsymbol{.} \psi \, d\lambda_E^{\partial} + \int_{E \cap \partial B(y,\delta)} \phi(x) \boldsymbol{.} \frac{1}{\delta}(x - y) \, \nu(dx)$$

for almost every $\delta > 0$.

proof (a) For $t > 0$, set

$$w(t) = \int_{E \cap \partial B(y,t)} \phi(x) \boldsymbol{.} \frac{1}{t}(x - y) \, \nu(dx)$$

when this is defined. By 265G, applied to functions of the form

$$x \mapsto \begin{cases} \phi(x) \boldsymbol{.} \frac{x-y}{\|x-y\|} & \text{if } x \in E \text{ and } 0 < \|x - y\| \leq \alpha, \\ 0 & \text{otherwise,} \end{cases}$$

w is defined almost everywhere in $]0, \infty[$ and is measurable (for Lebesgue measure on $\mathbb{R}$).

Let $\delta > 0$ be any point in the Lebesgue set of w (223D). Then

$$\lim_{t \downarrow 0} \frac{1}{t} \int_{\delta}^{\delta+t} |w(s) - w(\delta)| ds \leq 2 \lim_{t \downarrow 0} \frac{1}{2t} \int_{\delta-t}^{\delta+t} |w(s) - w(\delta)| = 0.$$

Let $\epsilon > 0$. Then there is an $\eta > 0$ such that

$$\frac{1}{\eta} \int_{\delta}^{\delta+\eta} |w(s) - w(\delta)| ds \leq \epsilon, \quad \int_{B(y,\delta+\eta) \setminus B(y,\delta)} \|\phi\| d\lambda_E^{\partial} \leq \epsilon,$$

$$\int_{B(y,\delta+\eta) \setminus B(y,\delta)} \| \operatorname{div} \phi \| d\mu \leq \epsilon.$$

(b) Set

$$\begin{aligned} g(x) &= 1 \text{ if } \|x-y\| \leq \delta, \\ &= 1 - \frac{1}{\eta}(\|x-y\| - \delta) \text{ if } \delta \leq \|x-y\| \leq \delta+\eta, \\ &= 0 \text{ if } \|x-y\| \geq \delta+\eta. \end{aligned}$$

Then g is continuous, and $\operatorname{grad} g(x) = \mathbf{0}$ if $\|x-y\| < \delta$ or $\|x-y\| > \delta+\eta$; while if $\delta < \|x-y\| < \delta+\eta$, $\operatorname{grad} g(x) = -\frac{x-y}{\eta\|x-y\|}$. This means that

$$\begin{aligned} \int_E \phi \boldsymbol{.} \operatorname{grad} g \, d\mu &= -\frac{1}{\eta}\int_\delta^{\delta+\eta} \int_{E\cap\partial B(y,t)} \frac{1}{t}(x-y) \boldsymbol{.} \phi(x)\, \nu(dx)dt \\ &= -\frac{1}{\eta}\int_\delta^{\delta+\eta} w(t)dt. \end{aligned}$$

By the choice of η,

$$|\textstyle\int_E \phi \boldsymbol{.} \operatorname{grad} g \, d\mu + w(\delta)| \leq \epsilon.$$

(c) By 474E and 474Bb we have

$$\int (g\times\phi)\boldsymbol{.}\psi \, d\lambda_E^\partial = \int_E \operatorname{div}(g\times\phi)d\mu$$

(of course $g\times\phi$ is Lipschitz, by 473Ca and 262Ba)

$$= \int_E \phi \boldsymbol{.} \operatorname{grad} g \, d\mu + \int_E g \times \operatorname{div}\phi \, d\mu.$$

Next, by the choice of η,

$$|\textstyle\int((g\times\phi)-\phi)\boldsymbol{.}\psi d\lambda_E^\partial| \leq \int_{B(y,\delta+\eta)\setminus B(y,\delta)} \|\phi\| d\lambda_E^\partial \leq \epsilon$$

and

$$\begin{aligned} \Big|\int_E \phi \boldsymbol{.} \operatorname{grad} g \, d\mu + \int_{E\cap\partial B(y,\delta)} \phi(x) \boldsymbol{.} \tfrac{1}{\delta}(x-y)\nu(dx)\Big| \\ = \Big|-\int_\delta^{\delta+\eta}\int_{\partial B(y,t)} \tfrac{x-y}{\eta\|x-y\|} \boldsymbol{.} \phi(x)\nu(dx)dt + w(\delta)\Big| \end{aligned}$$

(265G)

$$= \Big|-\frac{1}{\eta}\int_\delta^{\delta+\eta} w(t)dt + w(\delta)\Big| \leq \epsilon$$

and

$$\begin{aligned} \Big|\int_E g\times\operatorname{div}\phi\, d\mu - \int_{E\cap B(y,\delta)} \operatorname{div}\phi\, d\mu\Big| \\ \leq \int_{B(y,\delta+\eta)\setminus B(y,\delta)} \|\operatorname{div}\phi\| d\mu \leq \epsilon. \end{aligned}$$

Putting these together, we have

$$|\textstyle\int_{E\cap B(y,\delta)} \operatorname{div}\phi\, d\mu - \int_{B(y,\delta)} \phi\boldsymbol{.}\psi \, d\lambda_E^\partial - \int_{E\cap\partial B(y,\delta)} \phi(x)\boldsymbol{.}\frac{1}{\delta}(x-y)\nu(dx)| \leq 3\epsilon.$$

As ϵ is arbitrary, this gives the result.

474N Lemma Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter, and λ_E^∂ its perimeter measure. Then, for any $y \in \partial^\$ E$,

(i) $\liminf_{\delta\downarrow 0} \frac{\mu(B(y,\delta)\cap E)}{\mu B(y,\delta)} \geq \frac{1}{(3r)^r\beta_r}$;

(ii) $\liminf_{\delta\downarrow 0} \frac{\mu(B(y,\delta)\setminus E)}{\mu B(y,\delta)} \geq \frac{1}{(3r)^r\beta_r}$;

(iii) $\liminf_{\delta\downarrow 0} \frac{\lambda_E^\partial B(y,\delta)}{\delta^{r-1}} \geq \frac{1}{2c(3r)^r}$,

where $c = 2^{r+2}(1+\sqrt{r})(1+2^{r+1})$;

(iv) $\limsup_{\delta\downarrow 0} \frac{\lambda_E^\partial B(y,\delta)}{\delta^{r-1}} \leq 4\pi\beta_{r-2}$.

proof (a) Let ψ_E be the canonical outward-normal function of E (474G). Take $y \in \partial^\$ E$. Set

$$\Phi = \{\phi : \phi \text{ is a Lipschitz function from } \mathbb{R}^r \text{ to } B(\mathbf{0},1)\}.$$

Because the space $L^1(\mu)$ is separable in its usual (norm) topology (244I), so is $\{(\operatorname{div}\phi \times \chi B_1)^\bullet : \phi \in \Phi\}$, (4A2P(a-iv)), and there must be a countable set $\Phi_0 \subseteq \Phi$ such that

whenever $\phi \in \Phi$ and $m \in \mathbb{N}$ there is a $\hat\phi \in \Phi_0$ such that $\int_{B(y,1)} |\operatorname{div}\phi - \operatorname{div}\hat\phi| d\mu \leq 2^{-m}$.

Now, for each $\phi \in \Phi_0$,

$$\begin{aligned}|\int_{E\cap B(y,\delta)} \operatorname{div}\phi\, d\mu| &= |\int_{B(y,\delta)} \phi\cdot\psi_E\, d\lambda_E^\partial + \int_{E\cap\partial B(y,\delta)} \phi(x)\cdot\tfrac{1}{\delta}(x-y)\nu(dx)| \\ &\leq \lambda_E^\partial B(y,\delta) + \nu(E\cap\partial B(y,\delta))\end{aligned}$$

for almost every $\delta > 0$, by 474M. But this means that, for almost every $\delta \in]0,1]$,

$$\begin{aligned}\operatorname{per}(E\cap B(y,\delta)) &= \sup_{\phi\in\Phi} |\int_{E\cap B(y,\delta)} \operatorname{div}\phi\, d\mu| \\ &= \sup_{\phi\in\Phi_0} |\int_{E\cap B(y,\delta)} \operatorname{div}\phi\, d\mu| \leq \lambda_E^\partial B(y,\delta) + \nu(E\cap\partial B(y,\delta)).\end{aligned}$$

(b) It follows that, for some $\delta_0 > 0$,

$$\operatorname{per}(E\cap B(y,\delta)) \leq 3\nu(E\cap\partial B(y,\delta))$$

for almost every $\delta \in]0,\delta_0]$. **P** Applying 474M with $\phi(x) = \psi_E(y)$ for every x, we have

$$0 = \int_{B(y,\delta)} \psi_E(y)\cdot\psi_E(x)\lambda_E^\partial(dx) + \int_{E\cap\partial B(y,\delta)} \psi_E(y)\cdot\tfrac{1}{\delta}(x-y)\nu(dx)$$

for almost every $\delta \in [0,1]$. But by the definition of $\psi_E(y)$,

$$\lim_{\delta\downarrow 0} \frac{1}{\lambda_E^\partial B(y,\delta)} \int_{B(y,\delta)} \psi_E(y)\cdot\psi_E\, d\lambda_E^\partial = \lim_{\delta\downarrow 0} \frac{1}{\lambda_E^\partial B(y,\delta)} \int_{B(y,\delta)} \psi_E(y)\cdot\psi_E(y)\, d\lambda_E^\partial = 1.$$

So there is some $\delta_0 > 0$ such that, for almost every $\delta \in]0,\delta_0]$,

$$\begin{aligned}\lambda_E^\partial B(y,\delta) &\leq 2\int_{B(y,\delta)} \psi_E(y)\cdot\psi_E\, d\lambda_E^\partial \\ &= -2\int_{E\cap\partial B(y,\delta)} \psi_E(y)\cdot\tfrac{1}{\delta}(x-y)\nu(dx) \leq 2\nu(E\cap\partial B(y,\delta)).\end{aligned} \tag{1}$$

But this means that, for almost every such δ,

$$\operatorname{per}(E\cap B(y,\delta)) \leq \lambda_E^\partial B(y,\delta) + \nu(E\cap\partial B(y,\delta)) \leq 3\nu(E\cap\partial B(y,\delta)). \text{ } \mathbf{Q}$$

(c) Set $g(t) = \mu(E\cap B(y,t))$ for $t \geq 0$. By 265G, $g(t) = \int_0^t \nu(E\cap\partial B(y,s))ds$ for every t, so g is absolutely continuous on $[0,1]$ and $g'(t) = \nu(E\cap\partial B(y,t))$ for almost every t. Now we can estimate

$$g(t)^{(r-1)/r} = \mu(E \cap B(y,t))^{(r-1)/r} \leq \operatorname{per}(E \cap B(y,t))$$

(474La)

$$\leq 3\nu(E \cap \partial B(y,t)) = 3g'(t)$$

for almost every $t \in [0, \delta_0]$. So

$$\frac{d}{dt}\big(g(t)^{1/r}\big) = \frac{1}{r} g(t)^{(1-r)/r} g'(t) \geq \frac{1}{3r}$$

for almost every $t \in [0, \delta_0]$; since $t \mapsto g(t)^{1/r}$ is non-decreasing, $g(t)^{1/r} \geq \frac{t}{3r}$ (222C) and $g(t) \geq (3r)^{-r} t^r$ for every $t \in [0, \delta_0]$.

(d) Accordingly

$$\liminf_{\delta \downarrow 0} \frac{\mu(B(y,\delta) \cap E)}{\mu B(y,\delta)} \geq \inf_{0<\delta\leq\delta_0} \frac{\mu(B(y,\delta)\cap E)}{\mu B(y,\delta)} = \inf_{0<\delta\leq\delta_0} \frac{g(\delta)}{\beta_r \delta^r} \geq \frac{1}{(3r)^r \beta_r}.$$

This proves (i).

(e) Because $\lambda^{\partial}_{\mathbb{R}^r \setminus E} = \lambda^{\partial}_E$ and $-\psi_E$ is the canonical outward-normal function of $\mathbb{R}^r \setminus E$ (474J), y also belongs to $\partial^{\$}(\mathbb{R}^r \setminus E)$, so the second formula of this lemma follows from the first.

(f) By 474Lb,

$$\lambda^{\partial}_E B(y,\delta) \geq \frac{1}{2c} \min\big(\mu(B(y,\delta) \cap E), \mu(B(y,\delta) \setminus E)\big)^{(r-1)/r}$$

for every $\delta \geq 0$. So

$$\begin{aligned}\liminf_{\delta \downarrow 0} \frac{\lambda^{\partial}_E B(y,\delta)}{\delta^{r-1}} &\geq \frac{1}{2c} \liminf_{\delta \downarrow 0} \min\big(\frac{\mu(B(y,\delta) \cap E)}{\delta^r}, \frac{\mu(B(y,\delta) \setminus E)}{\delta^r}\big)^{(r-1)/r} \\ &\geq \frac{1}{2c(3r)^r}.\end{aligned}$$

Thus (iii) is true.

(g) Returning to the inequality (1) in the proof of (b) above, we have a $\delta_0 > 0$ such that

$$\lambda^{\partial}_E B(y,\delta) \leq 2\nu(E \cap \partial B(y,\delta)) \leq 2\nu(\partial B(y,\delta)) = 4\pi\beta_{r-2}\delta^{r-1}$$

for almost every $\delta \in]0, \delta_0]$. But this means that, for any $\delta \in [0, \delta_0[$,

$$\lambda^{\partial}_E B(y,\delta) \leq \inf_{t>\delta} \lambda^{\partial}_E B(y,t) \leq \inf_{t>\delta} 4\pi\beta_{r-2}t^{r-1} = 4\pi\beta_{r-2}\delta^{r-1},$$

and (iv) is true.

474O Definition Let $A \subseteq \mathbb{R}^r$ be any set, and $y \in \mathbb{R}^r$. A **Federer exterior normal to** A **at** y is a $v \in S_{r-1}$ such that,

$$\lim_{\delta \downarrow 0} \frac{\mu^*((H \triangle A) \cap B(y,\delta))}{\mu B(y,\delta)} = 0,$$

where H is the half-space $\{x : (x-y) \boldsymbol{.} v \leq 0\}$.

474P Lemma If $A \subseteq \mathbb{R}^r$ and $y \in \mathbb{R}^r$, there can be at most one Federer exterior normal to A at y.

proof Suppose that v, $v' \in S_{r-1}$ are two Federer exterior normals to E at y. Set

$$H = \{x : (x-y) \boldsymbol{.} v \leq 0\}, \quad H' = \{x : (x-y) \boldsymbol{.} v' \leq 0\}.$$

Then

$$\lim_{\delta \downarrow 0} \frac{\mu((H \triangle H') \cap B(y,\delta))}{\mu B(y,\delta)} \leq \lim_{\delta \downarrow 0} \frac{\mu^*((H \triangle A) \cap B(y,\delta))}{\mu B(y,\delta)} + \lim_{\delta \downarrow 0} \frac{\mu^*((H' \triangle A) \cap B(y,\delta))}{\mu B(y,\delta)} = 0.$$

But for any $\delta > 0$,

$$(H \triangle H') \cap B(y,\delta) = y + \delta((H_0 \triangle H_0') \cap B(\mathbf{0},1)),$$

where

$$H_0 = \{x : x \boldsymbol{.} v \leq 0\}, \quad H_0' = \{x : x \boldsymbol{.} v' \leq 0\}.$$

So

$$0 = \lim_{\delta \downarrow 0} \frac{\mu((H \triangle H') \cap B(y,\delta))}{\mu B(y,\delta)} = \frac{\mu((H_0 \triangle H_0') \cap B(\mathbf{0},1))}{\mu B(\mathbf{0},1)} = \frac{\mu((H_0 \triangle H_0') \cap B(\mathbf{0},n))}{\mu B(\mathbf{0},n)}$$

for every $n \geq 1$, and $\mu(H_0 \triangle H_0') = 0$. Since μ is strictly positive, and H_0 and H_0' are both the closures of their interiors, they must be identical; and it follows that $v = v'$.

474Q Theorem Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter, λ_E^∂ its perimeter measure, ψ_E its canonical outward-normal function, and y any point of its reduced boundary $\partial^\$ E$. Then $\psi_E(y)$ is the Federer exterior normal to E at y.

proof (a) To begin with (down to the end of (i) below) suppose that $y = \mathbf{0}$ and that $\psi_E(y) = (0, \ldots, 0, 1) = v$ say. Set

$$c_0 = \frac{2^{r+2}\pi\beta_{r-1}}{r\beta_r}, \quad c' = 2^{r+1}(1 + \sqrt{r-1})(1 + 2^r),$$

(counting β_0 as 1, if $r = 2$),

$$c_1 = 1 + \max\big(4\pi\beta_{r-2}, (3r)^r 2^{r+3}(1 + \sqrt{r})(1 + 2^{r+1})\big),$$

$$c_2 = 2^{(r+1)/2} c_1, \quad c_3 = \frac{c_2}{2} + \frac{8c'}{\beta_{r-1}}.$$

For $\delta > 0$ let C_δ be the solid cylinder

$$\{x : \textstyle\sum_{i=1}^{r-1} \xi_i^2 \leq \delta^2, \, |\xi_r| \leq \delta\}.$$

For $\gamma \in \mathbb{R}$ set

$$\tilde{H}(\gamma) = \{x : \xi_r \leq \gamma\}.$$

For each $\delta > 0$, choose $\gamma_\delta \in \mathbb{R}$ such that

$$\mu((E \triangle \tilde{H}(\gamma_\delta)) \cap C_\delta) \leq \delta \mu C_\delta + \inf_{\gamma \in \mathbb{R}} \mu((E \triangle \tilde{H}(\gamma)) \cap C_\delta).$$

(b) Take any $\epsilon > 0$ such that

$$\epsilon < \frac{1}{\sqrt{2}}, \quad 4c'\epsilon < \frac{1}{8}\beta_{r-1}, \quad c_2\epsilon^3 < \frac{1}{4}\beta_{r-1}.$$

Then there is a $\delta_0 \in]0,1]$ such that

$$\frac{1}{\lambda_E^\partial B(\mathbf{0},\delta)} \int_{B(\mathbf{0},\delta)} \|\psi_E(x) - v\| \lambda_E^\partial(dx) \leq \epsilon^3,$$

$$\frac{1}{c_1}\delta^{r-1} \leq \lambda_E^\partial B(\mathbf{0},\delta) \leq c_1 \delta^{r-1}$$

for every $\delta \in \left]0, \delta_0\sqrt{2}\right]$ (using 474N(iii) and 474N(iv) for the inequalities bounding $\lambda_E^\partial B(\mathbf{0},\delta)$). Then

$$B(\mathbf{0},\delta) \subseteq C_\delta \subseteq B(\mathbf{0},\delta\sqrt{2}),$$

so

$$\begin{aligned}\int_{C_\delta} \|\psi_E(x) - v\| \lambda_E^\partial(dx) &\leq \int_{B(\mathbf{0},\delta\sqrt{2})} \|\psi_E(x) - v\| \lambda_E^\partial(dx) \\ &\leq \epsilon^3 \lambda_E^\partial B(\mathbf{0},\delta\sqrt{2}) \leq 2^{(r-1)/2} c_1 \epsilon^3 \delta^{r-1} = \frac{1}{2} c_2 \epsilon^3 \delta^{r-1}\end{aligned}$$

whenever $0 < \delta \leq \delta_0$.

For each $n \in \mathbb{N}$, set $f_n = \tilde{h}_n * \chi E$, where $\tilde{h}_n$ is the smoothing function of 473E, so that f_n is smooth and Lipschitz (473Df) and $\operatorname{grad} f_n$ is bounded (473Cc). For $n \in \mathbb{N}$, $t \in \mathbb{R}$ set

$$F_n = \{x : x \in \mathbb{R}^r,\ f_n(x) \geq \tfrac{3}{4}\}, \quad F_n' = \{x : x \in \mathbb{R}^r,\ f_n(x) \leq \tfrac{1}{4}\},$$

$$f_{nt}(z) = f_n(z,t) \text{ for } z \in \mathbb{R}^{r-1},$$

identifying $\mathbb{R}^r$ with $\mathbb{R}^{r-1} \times \mathbb{R}$,

$$F_{nt} = \{z : z \in \mathbb{R}^{r-1},\ f_{nt}(z) \geq \tfrac{3}{4}\}, \quad F_{nt}' = \{z : z \in \mathbb{R}^{r-1},\ f_{nt}(z) \leq \tfrac{1}{4}\}.$$

Write $V_\delta \subseteq \mathbb{R}^{r-1}$ for the ball $\{z : \|z\| \leq \delta\}$, so that C_δ is $V_\delta \times [-\delta, \delta]$. Set

$$\gamma_{\delta n} = \sup\big(\{-\delta\} \cup \{t : t \in [-\delta,\delta],\ \mu_{r-1}(F_{nt} \cap V_\delta) \geq \tfrac{3}{4}\mu V_\delta\}\big),$$

$$G_{\delta n} = \{t : t \in [-\delta,\delta],\ \textstyle\int_{V_\delta} \|\operatorname{grad} f_{nt}\| d\mu_{r-1} > \epsilon^2(\delta + \frac{1}{n+1})^{r-2}\}.$$

The aim of the main part of the proof is to show that, for small δ and large n, $C_\delta \cap F_n$ is well approximated by $C_\delta \cap \tilde{H}(\gamma_{\delta n})$.

(c) For the time being (down to the end of (f) below) fix $\delta > 0$ and $n \in \mathbb{N}$ such that

$$\delta + \tfrac{1}{n+1} \leq \delta_0, \quad 4c'\epsilon(\delta + \tfrac{1}{n+1})^{r-1} \leq \tfrac{1}{8}\beta_{r-1}\delta^{r-1},$$

$$c_2\epsilon^3(\delta + \tfrac{1}{n+1})^{r-1} < \tfrac{1}{4}\beta_{r-1}\delta^{r-1}.$$

For $f : \mathbb{R}^r \to \mathbb{R}$ set

$$\operatorname{grad}_{r-1} f = \operatorname{grad} f - (v \boldsymbol{.} \operatorname{grad} f)v = (\tfrac{\partial f}{\partial \xi_1}, \dots, \tfrac{\partial f}{\partial \xi_{r-1}}, 0);$$

for definiteness, take the domain of $\operatorname{grad}_{r-1} f$ to be the set of points at which f is differentiable. Then

$$\textstyle\int_{C_\delta} \|\operatorname{grad}_{r-1} f_n\| + \max(\frac{\partial f_n}{\partial \xi_r}, 0) d\mu \leq c_2\epsilon^3(\delta + \frac{1}{n+1})^{r-1}.$$

P? Suppose, if possible, otherwise. Note that because $\mu C_\delta = 2\beta_{r-1}\delta^r$ (by Fubini's theorem), $\lim_{\delta' \uparrow \delta} \mu C_{\delta'} = \mu C_\delta$, so there is some $\delta' < \delta$ such that

$$\textstyle\int_{C_{\delta'}} \|\operatorname{grad}_{r-1} f_n\| + \max(\frac{\partial f_n}{\partial \xi_r}, 0) d\mu > c_2\epsilon^3(\delta + \frac{1}{n+1})^{r-1}.$$

For $1 \leq i < r$, set

$$\begin{aligned} \theta_i(x) &= \frac{\frac{\partial f_n}{\partial \xi_i}(x)}{\|\operatorname{grad}_{r-1} f_n(x)\|} \text{ when } x \in C_{\delta'} \text{ and } \operatorname{grad}_{r-1} f_n(x) \neq 0, \\ &= 0 \text{ otherwise;} \end{aligned}$$

and set

$$\begin{aligned} \theta_r(x) &= \frac{\max(\frac{\partial f_n}{\partial \xi_r}(x), 0)}{|\frac{\partial f_n}{\partial \xi_r}(x)|} \text{ when } x \in C_{\delta'} \text{ and } \tfrac{\partial f_n}{\partial \xi_r}(x) \neq 0, \\ &= 0 \text{ otherwise.} \end{aligned}$$

Then $\theta : \mathbb{R}^r \to \mathbb{R}^r$ is Lebesgue measurable and $\|\theta\| \leq \sqrt{2}\chi C_{\delta'}$, so all the θ_i are μ-integrable, while

$$\textstyle\int \theta \boldsymbol{.} \operatorname{grad} f_n d\mu = \int_{C_{\delta'}} \|\operatorname{grad}_{r-1} f_n\| + \max(\frac{\partial f_n}{\partial \xi_r}, 0) d\mu > c_2\epsilon^3(\delta + \frac{1}{n+1})^{r-1}.$$

By 473Ef, $\langle \|\theta_i - \theta_i * \tilde{h}_k\|_1 \rangle_{k \in \mathbb{N}} \to 0$ for each i; since $\operatorname{grad} f_n$ is bounded,

$$\int (\tilde{h}_k * \theta) \cdot \operatorname{grad} f_n \, d\mu > c_2 \epsilon^3 (\delta + \tfrac{1}{n+1})^{r-1}$$

for any k large enough; if we ensure also that $\frac{1}{k+1} \leq \delta - \delta'$, and set $\phi = \tilde{h}_k * \theta$, we shall get a smooth function ϕ, with $\|\phi\| \leq \sqrt{2}\chi C_\delta$ (by 473Dc and 473Dg), such that

$$\int \phi \cdot \operatorname{grad} f_n d\mu > c_2 \epsilon^3 (\delta + \tfrac{1}{n+1})^{r-1}.$$

Moreover,

$$(\tilde{h}_n * \phi)(x) \cdot v = (\tilde{h}_n * (\tilde{h}_k * \theta_r))(x) \geq 0$$

for every x, because $\tilde{h}_n$, $\tilde{h}_k$ ant θ_r are all non-negative.

Now ϕ is smooth (473De) and has compact support, so

$$\begin{aligned} c_2 \epsilon^3 (\delta + \tfrac{1}{n+1})^{r-1} &< \int \phi \cdot \operatorname{grad} f_n d\mu = \int \phi \cdot \operatorname{grad}(\tilde{h}_n * \chi E) d\mu \\ &= -\int (\tilde{h}_n * \phi) \cdot \psi_E \, d\lambda_E^\partial \end{aligned}$$

(474K)

$$\leq \int (\tilde{h}_n * \phi) \cdot (v - \psi_E) \, d\lambda_E^\partial \leq 2 \int_{C_{\delta + (1/n+1)}} \|v - \psi_E\| \, d\lambda_E^\partial$$

(because $\|(\tilde{h}_n * \phi)(x)\| \leq \sqrt{2}$ for every x, by 473Dg again, and $(\tilde{h}_n * \phi)(x) = 0$ if $x \notin C_{\delta+(1/n+1)}$)

$$\leq c_2 \epsilon^3 (\delta + \tfrac{1}{n+1})^{r-1};$$

which is absurd. **XQ**

(d) Observe that

$$\operatorname{grad}_{r-1} f_n(z,t) = (\operatorname{grad} f_{nt}(z), 0)$$

for all z and t. So (c) tells us that

$$\begin{aligned} \int_{-\delta}^{\delta} \int_{V_\delta} \|\operatorname{grad} f_{nt}(z)\| \mu_{r-1}(dz) dt &= \int_{C_\delta} \|\operatorname{grad}_{r-1} f_n(x)\| \mu(dx) \\ &\leq c_2 \epsilon^3 (\delta + \tfrac{1}{n+1})^{r-1}. \end{aligned}$$

So, writing μ_1 for Lebesgue measure on $\mathbb{R}$, $\mu_1 G_{\delta n} \leq c_2 \epsilon (\delta + \frac{1}{n+1})$.

If $t \in [-\delta, \delta] \setminus G_{\delta n}$, then

$$\min(\mu_{r-1}(F'_{nt} \cap V_\delta), \mu_{r-1}(F_{nt} \cap V_\delta)) \leq 4c' \epsilon (\delta + \tfrac{1}{n+1})^{r-1}.$$

P If $r > 2$,

$$\min\big(\mu_{r-1}(F'_{nt} \cap V_\delta), \mu_{r-1}(F_{nt} \cap V_\delta)\big)^{(r-2)/(r-1)} \leq 4c' \int_{V_\delta} \|\operatorname{grad} f_{nt}\| d\mu_{r-1}$$

(473L)

$$\leq 4c' \epsilon^2 (\delta + \tfrac{1}{n+1})^{r-2},$$

so that

$$\min(\mu_{r-1}(F'_{nt}\cap V_\delta),\mu_{r-1}(F_{nt}\cap V_\delta)) \le (4c'\epsilon^2)^{(r-1)/(r-2)}(\delta+\tfrac{1}{n+1})^{r-1}$$
$$\le 4c'\epsilon(\delta+\tfrac{1}{n+1})^{r-1}$$

because $4c'\ge 1$ and $\frac{2(r-1)}{r-2}\ge 1$ and $\epsilon\le 1$. If $r=2$, then

$$\int_{V_\delta}\|\operatorname{grad} f_{nt}\|d\mu_{r-1}\le\epsilon^2<\tfrac{1}{2},$$

so at least one of $F'_{nt}\cap V_\delta$, $F_{nt}\cap V_\delta$ is empty, as noted in 473M, and $\min(\mu_{r-1}(F'_{nt}\cap V_\delta),\mu_{r-1}(F_{nt}\cap V_\delta))=0$. **Q**

(e) The next thing to note is that $\mu_{r-1}(F'_{ns}\cap V_\delta)<\frac{3}{4}\mu_{r-1}V_\delta$ whenever $-\delta\le s<\gamma_{\delta n}$. **P?** Otherwise, we have $-\delta\le s\le t\le\delta$ such that

$$\mu_{r-1}(F'_{ns}\cap V_\delta)\ge\tfrac{3}{4}\mu_{r-1}V_\delta,\quad \mu_{r-1}(F_{nt}\cap V_\delta)\ge\tfrac{3}{4}\mu_{r-1}V_\delta,$$

so that

$$\mu_{r-1}(F'_{ns}\cap F_{nt}\cap V_\delta)\ge\tfrac{1}{2}\mu_{r-1}V_\delta.$$

But for any $z\in F'_{ns}\cap F_{nt}\cap V_\delta$, $f_n(z,s)\le\frac14$ and $f_n(z,t)\ge\frac34$, so

$$\int_{-\delta}^{\delta}\max(\tfrac{\partial f_n}{\partial\xi_r}(z,\xi),0)d\xi\ge\int_s^t\tfrac{\partial f_n}{\partial\xi_r}(z,\xi)d\xi=f_n(z,t)-f_n(z,s)\ge\tfrac12.$$

Accordingly

$$\int_{C_\delta}\max(\tfrac{\partial f_n}{\partial\xi_r}(x),0)\mu(dx)=\int_{V_\delta}\int_{-\delta}^{\delta}\max(\tfrac{\partial f_n}{\partial\xi_r}(z,\xi),0)d\xi\,\mu_{r-1}(dz)$$
$$\ge\tfrac12\mu_{r-1}(F'_{ns}\cap F_{nt}\cap V_\delta)\ge\tfrac14\mu_{r-1}V_\delta$$
$$=\tfrac14\beta_{r-1}\delta^{r-1}>c_2\epsilon^3(\delta+\tfrac{1}{n+1})^{r-1}$$

by the choice of δ and n; but this contradicts (c). **XQ**

(f) Now

$$\mu((F_n\triangle\tilde H(\gamma_{\delta n}))\cap C_\delta)\le 9\mu(C_\delta\setminus(F_n\cup F'_n))+c_2\epsilon(\delta+\tfrac{1}{n+1})\mu_{r-1}V_\delta$$
$$+16c'\epsilon\delta(\delta+\tfrac{1}{n+1})^{r-1}.$$

P Set

$$\tilde G=\{t:-\delta\le t\le\delta,\ \mu_{r-1}(V_\delta\setminus(F_{nt}\cup F'_{nt}))\ge\tfrac18\mu_{r-1}V_\delta\},$$

$$\hat G=\{t:-\delta\le t\le\delta,\ \mu_{r-1}(F_{nt}\cap V_\delta)\le 4c'\epsilon(\delta+\tfrac{1}{n+1})^{r-1}\},$$

$$\hat G'=\{t:-\delta\le t\le\delta,\ \mu_{r-1}(F'_{nt}\cap V_\delta)\le 4c'\epsilon(\delta+\tfrac{1}{n+1})^{r-1}\};$$

so that $G_{\delta n}\cup\hat G\cup\hat G'=[-\delta,\delta]$, by (d). Then

$$\tfrac18\mu_{r-1}V_\delta\cdot\mu_1\tilde G\le\mu(C_\delta\setminus(F_n\cup F'_n)),$$

$$\mu(F_n \cap (V_\delta \times \hat{G})) \leq 8c'\epsilon\delta(\delta + \tfrac{1}{n+1})^{r-1},$$

$$\mu(F'_n \cap (V_\delta \times \hat{G}')) \leq 8c'\epsilon\delta(\delta + \tfrac{1}{n+1})^{r-1}.$$

So if we set

$$W = (C_\delta \setminus (F_n \cup F'_n)) \cup (V_\delta \times (\tilde{G} \cup G_{\delta n} \cup \{\gamma_{\delta n}\})) \cup (F_n \cap (V_\delta \times \hat{G})) \cup (F'_n \cap (V_\delta \times \hat{G}')),$$

we shall have

$$\begin{aligned}\mu W &\leq \mu(C_\delta \setminus (F_n \cup F'_n)) + \mu_1\tilde{G} \cdot \mu_{r-1}V_\delta + \mu_1 G_{\delta n} \cdot \mu_{r-1}V_\delta + 16c'\epsilon\delta(\delta + \tfrac{1}{n+1})^{r-1} \\ &\leq 9\mu(C_\delta \setminus (F_n \cup F'_n)) + c_2\epsilon(\delta + \tfrac{1}{n+1})\mu_{r-1}V_\delta + 16c'\epsilon\delta(\delta + \tfrac{1}{n+1})^{r-1}\end{aligned}$$

(using the first part of (d) to estimate $\mu_1 G_{\delta n}$).

? Suppose, if possible, that there is a point $(z,t) \in (F_n \triangle \tilde{H}(\gamma_{\delta n})) \cap C_\delta \setminus W$. Since $t \notin G_{\delta n}$, (d) tells us that

$$\min(\mu_{r-1}(F'_{nt} \cap V_\delta), \mu_{r-1}(F_{nt} \cap V_\delta)) \leq 4c'\epsilon(\delta + \tfrac{1}{n+1})^{r-1} \leq \tfrac{1}{8}\mu_{r-1}V_\delta$$

by the choice of δ and n. So $t \in \hat{G} \cup \hat{G}'$. Also, since $t \notin \tilde{G}$, $\mu_{r-1}F_{nt} + \mu_{r-1}F'_{nt} \geq \frac{7}{8}\mu_{r-1}V_\delta$; so (since $t \neq \gamma_{\delta n}$) either $\mu_{r-1}F_{nt} \geq \frac{3}{4}\mu_{r-1}V_\delta$ and $t < \gamma_{\delta n}$, or $\mu_{r-1}F'_{nt} \geq \frac{3}{4}\mu_{r-1}V_\delta$ and $t > \gamma_{\delta n}$ (by (e)). Now

$$\begin{aligned}t < \gamma_{\delta n} &\implies \mu_{r-1}(F_{nt} \cap V_\delta) \geq \tfrac{3}{4}\mu_{r-1}V_\delta \\ &\implies \mu_{r-1}(F'_{nt} \cap V_\delta) \leq 4c'\epsilon(\delta + \tfrac{1}{n+1})^{r-1} \\ &\implies t \in \hat{G}' \\ &\implies (z,t) \notin F'_n \\ &\text{(because } (z,t) \notin F'_n \cap (V_\delta \times \hat{G}')) \\ &\implies (z,t) \in F_n \\ &\text{(because } (z,t) \notin C_\delta \setminus (F_n \cup F'_n)) \\ &\implies (z,t) \in F_n \cap \tilde{H}(\gamma_{\delta n}) \cap C_\delta,\end{aligned}$$

which is impossible. And similarly

$$\begin{aligned}t > \gamma_{\delta n} &\implies \mu_{r-1}(F'_{nt} \cap V_\delta) \geq \tfrac{3}{4}\mu_{r-1}V_\delta \\ &\implies \mu_{r-1}(F_{nt} \cap V_\delta) \leq 4c'\epsilon(\delta + \tfrac{1}{n+1})^{r-1} \\ &\implies t \in \hat{G} \\ &\implies (z,t) \notin F_n \\ &\implies (z,t) \notin F_n \cup \tilde{H}(\gamma_{\delta n}),\end{aligned}$$

which is equally impossible. **X**

Thus $(F_n \triangle \tilde{H}(\gamma_{\delta n})) \cap C_\delta \subseteq W$ has measure at most

$$9\mu(C_\delta \setminus (F_n \cup F'_n)) + c_2\epsilon(\delta + \tfrac{1}{n+1})\mu_{r-1}V_\delta + 16c'\epsilon\delta(\delta + \tfrac{1}{n+1})^{r-1},$$

as claimed. **Q**

(g) All this has been with fixed δ and n. Now take $\delta \in]0, \delta_0[$ and let $n \to \infty$. In this case, $f_n \to \chi E$ a.e. (473Ee), so

$$\lim_{n\to\infty} \mu((E \triangle F_n) \cap C_\delta = \lim_{n\to\infty} \mu(C_\delta \setminus (F_n \cup F_n')) = 0,$$

and

$$\begin{aligned}\limsup_{n\to\infty} \mu((E \triangle \tilde{H}(\gamma_{\delta n})) \cap C_\delta) &= \limsup_{n\to\infty} \mu((F_n \triangle \tilde{H}(\gamma_{\delta n})) \cap C_\delta) \\ &\leq c_2 \epsilon \delta \mu_{r-1} V_\delta + 16 c' \epsilon \delta^r = c_3 \epsilon \mu C_\delta.\end{aligned}$$

Now

$$\begin{aligned}\mu((E \triangle \tilde{H}(\gamma_\delta)) \cap C_\delta) &\leq \delta \mu C_\delta + \inf_{n\in\mathbb{N}} \mu((E \triangle \tilde{H}(\gamma_{\delta n})) \cap C_\delta) \\ &\leq (\delta + c_3 \epsilon) \mu C_\delta\end{aligned}$$

by the choice of γ_δ ((a) above). Since ϵ is arbitrary, this means that

$$\limsup_{\delta\downarrow 0} \frac{1}{\mu C_\delta} \mu((E \triangle \tilde{H}(\gamma_\delta)) \cap C_\delta) = 0.$$

(h) Now $\lim_{\delta\downarrow 0} \frac{\gamma_\delta}{\delta} = 0$. **P** Let $\epsilon \in]0, 1]$. Then by (g) above and 474N there is a $\delta_0 > 0$ such that

$$\mu((E \triangle \tilde{H}(\gamma_\delta)) \cap C_\delta) < \frac{\epsilon^r}{4\beta_{r-1}(3r)^r} \mu C_\delta,$$

$$\mu(B(\mathbf{0}, \delta) \cap E) \geq \frac{1}{2(3r)^r \beta_r} \mu B(\mathbf{0}, \delta),$$

$$\mu B(\mathbf{0}, \delta) \setminus E) \geq \frac{1}{2(3r)^r \beta_r} \mu B(\mathbf{0}, \delta)$$

whenever $0 < \delta \leq \delta_0$. **?** Suppose, if possible, that $0 < \delta \leq \delta_0$ and $\gamma_\delta \leq -\epsilon\delta$. Then

$$\begin{aligned}\mu(E \cap B(\mathbf{0}, \epsilon\delta)) &\leq \mu(E \cap C_\delta \setminus \tilde{H}(\gamma_\delta)) \\ &< \frac{\epsilon^r}{4\beta_{r-1}(3r)^r} \mu C_\delta = \frac{1}{2\beta_r (3r)^r} \mu B(\mathbf{0}, \epsilon\delta)\end{aligned}$$

which is impossible. **X** So $-\epsilon\delta \leq \gamma_\delta$ for all $\delta \in]0, \delta_0]$. In the same way, $\gamma_\delta \leq \epsilon\delta$ for all $\delta \in]0, \delta_0]$. As ϵ is arbitrary, we have the result. **Q**

(i) This means that

$$\lim_{\delta\downarrow 0} \frac{\mu((E \triangle \tilde{H}(0)) \cap C_\delta)}{\mu C_\delta} \leq \lim_{\delta\downarrow 0} \frac{\mu((E \triangle \tilde{H}(\gamma_\delta)) \cap C_\delta)}{\mu C_\delta} + \lim_{\delta\downarrow 0} \frac{\gamma_\delta}{\delta} = 0,$$

and

$$\lim_{\delta\downarrow 0} \frac{\mu((E \triangle \tilde{H}(0)) \cap B_\delta)}{\mu B_\delta} \leq \frac{2\beta_{r-1}}{\beta_r} \lim_{\delta\downarrow 0} \frac{\mu((E \triangle \tilde{H}(0)) \cap C_\delta)}{\mu C_\delta} = 0.$$

(j) Thus v is a Federer exterior normal to E at $\mathbf{0}$ if $\psi_E(\mathbf{0}) = v$. For the general case, let S be an orthogonal matrix such that $S\psi_E(y) = v$, and set $T(x) = S(x - y)$ for every x, so that $T(y) = \mathbf{0}$. The point is of course that $\mathbf{0} \in \partial^{\$} T[E]$ and $\psi_{T[E]}(\mathbf{0}) = v$. **P** Because $\lambda^\partial_{T[E]} = \lambda^\partial_E T^{-1}$ and $S\psi_E T^{-1}$ is an outward-normal function for $T[E]$ (474H),

$$\frac{1}{\lambda^\partial_{T[E]}B(\mathbf{0},\delta)}\int_{B(\mathbf{0},\delta)}\|S\psi_E T^{-1}(x)-v\|\lambda^\partial_{T[E]}(x)$$
$$=\frac{1}{\lambda^\partial_E T^{-1}[B(\mathbf{0},\delta)]}\int_{T[B(y,\delta)]}\|S\psi_E T^{-1}(x)-v\|(\lambda^\partial_E T^{-1})(dx)$$
$$=\frac{1}{\lambda^\partial_E B(y,\delta)}\int_{B(y,\delta)}\|S\psi_E(x)-v\|\lambda^\partial_E(dx)$$

(by 235I, because T^{-1} is inverse-measure-preserving for $\lambda^\partial_E T^{-1}$ and λ^∂_E)

$$=\frac{1}{\lambda^\partial_E B(y,\delta)}\int_{B(y,\delta)}\|\psi_E(x)-S^{-1}v\|\lambda^\partial_E(dx)$$
$$=\frac{1}{\lambda^\partial_E B(y,\delta)}\int_{B(y,\delta)}\|\psi_E(x)-\psi_E(y)\|\lambda^\partial_E(dx)\to 0$$

as $\delta\downarrow 0$. **Q**

Now consider

$$H=\{x:(x-y)\boldsymbol{.}\psi_E(y)\le 0\}=\{x:T(x)\boldsymbol{.}v\le 0\}=T^{-1}[\tilde H(0)].$$

Then

$$\frac{\mu((H\triangle E)\cap B(y,\delta))}{\mu B(y,\delta)}=\frac{\mu((\tilde H(0)\triangle T[E])\cap B(\mathbf{0},\delta))}{\mu B(\mathbf{0},\delta)}\to 0$$

as $\delta\downarrow 0$, so $\psi_E(y)$ is a Federer exterior normal to E at y, as required.

474R Corollary Let $E\subseteq\mathbb{R}^r$ be a set with locally finite perimeter, and λ^∂_E its perimeter measure. Let y be any point of the reduced boundary of E. Then

$$\lim_{\delta\downarrow 0}\frac{\lambda^\partial_E B(y,\delta)}{\beta_{r-1}\delta^{r-1}}=1.$$

proof (a) Set $v=\psi_E(y)$ and $H=\{x:(x-y)\boldsymbol{.}v\le 0\}$, as in 474Q. Now

$$\int_{H\cap\partial B(y,\delta)}v\boldsymbol{.}\tfrac{1}{\delta}(x-y)\nu(dx)=-\beta_{r-1}\delta^{r-1}$$

for almost every $\delta>0$. **P** Set $\phi(x)=v$ for every $x\in\mathbb{R}^r$. By 474I, ϕ is an outward-normal function for H, so 474M tells us that, for almost every $\delta>0$,

$$\int_{H\cap\partial B(y,\delta)}v\boldsymbol{.}\tfrac{1}{\delta}(x-y)\,\nu(dx)=\int_{H\cap B(y,\delta)}\operatorname{div}\phi\,d\mu-\int_{B(y,\delta)}v\boldsymbol{.}v\,d\lambda^\partial_H$$
$$=-\lambda^\partial_H B(y,\delta)=-\nu(B(y,\delta)\cap\partial H)$$

(using the identification of λ^∂_H in 474I)

$$=-\beta_{r-1}\delta^{r-1}$$

(identifying ν on the hyperplane ∂H with Lebesgue measure on $\mathbb{R}^{r-1}$, as usual). **Q**

(b) Now, given $\epsilon>0$, there is a $\delta_0>0$ such that whenever $0<\delta\le\delta_0$ there is an η such that $\delta\le\eta\le\delta(1+\epsilon)$ and $|\lambda^\partial_E B(y,\eta)-\beta_{r-1}\eta^{r-1}|\le\epsilon\delta^{r-1}$. **P** Let $\zeta>0$ be such that

$$\zeta(1+\frac{5\pi}{r}\beta_{r-2})(1+\epsilon)^r\le\epsilon^2.$$

By 474N(iv) and 474Q and the definition of ψ_E, there is a $\delta_0>0$ such that

$$\lambda^\partial_E B(y,\delta)\le 5\pi\beta_{r-2}\delta^{r-1},$$

$$\mu((E\triangle H)\cap B(y,\delta))\le\zeta\delta^r,$$

$$\int_{B(y,\delta)} \|\psi_E(x) - v\| \lambda_E^\partial(dx) \leq \zeta \lambda_E^\partial B(y,\delta)$$

whenever $0 < \delta \leq (1+\epsilon)\delta_0$. Take $0 < \delta \leq \delta_0$. Then, for almost every $\eta > 0$, we have

$$\int_{B(y,\eta)} v \bullet \psi_E(x)\, \lambda_E^\partial(dx) + \int_{E \cap \partial B(y,\eta)} v \bullet \frac{1}{\eta}(x-y)\, \nu(dx) = 0$$

by 474M, applied with $\phi \equiv v$. Putting this together with (a), we see that, for almost every $\eta \in]0, \delta_0]$,

$$\begin{aligned}
&|\lambda_E^\partial B(y,\eta) - \beta_{r-1}\eta^{r-1}| \\
&\quad \leq \int_{B(y,\eta)} \|\psi_E(x) - v\| \lambda_E^\partial(dx) \\
&\qquad + |\int_{B(y,\eta)} v \bullet \psi_E(x)\, \lambda_E^\partial(dx) + \int_{H \cap \partial B(y,\eta)} v \bullet \frac{1}{\eta}(x-y)\, \nu(dx)| \\
&\quad \leq \zeta \lambda_E^\partial B(y,\eta) \\
&\qquad + |\int_{H \cap \partial B(y,\eta)} v \bullet \frac{1}{\eta}(x-y)\, \nu(dx) - \int_{E \cap \partial B(y,\eta)} v \bullet \frac{1}{\eta}(x-y)\, \nu(dx)| \\
&\quad \leq 5\pi\beta_{r-2}\zeta\eta^{r-1} + \nu((E \triangle H) \cap \partial B(y,\eta)).
\end{aligned}$$

Integrating with respect to η, we have

$$\int_0^{\delta(1+\epsilon)} |\lambda_E^\partial B(y,\eta) - \beta_{r-1}\eta^{r-1}| d\eta \leq \frac{5\pi}{r}\beta_{r-2}\zeta\delta^r(1+\epsilon)^r + \mu((E \triangle H) \cap B(y, \delta(1+\epsilon)))$$

(using 265G, as usual)

$$\leq \frac{5\pi}{r}\beta_{r-2}\zeta\delta^r(1+\epsilon)^r + \zeta\delta^r(1+\epsilon)r \leq \epsilon^2\delta^r$$

by the choice of ζ. But this means that there must be some $\eta \in [\delta, \delta(1+\epsilon)]$ such that

$$|\lambda_E^\partial B(y,\eta) - \beta_{r-1}\eta^{r-1}| \leq \epsilon\delta^{r-1} \leq \epsilon\eta^{r-1}. \quad \blacksquare$$

(c) Now we see that

$$\lambda_E^\partial B(y,\delta) \leq \lambda_E^\partial B(y,\eta) \leq (\beta_{r-1} + \epsilon)\eta^{r-1} \leq (\beta_{r-1} + \epsilon)(1+\epsilon)^{r-1}\delta^{r-1}.$$

But by the same argument we have an $\hat\eta \in [\frac{\delta}{1+\epsilon}, \delta]$ such that $|\lambda_E^\partial B(y,\hat\eta) - \beta_{r-1}\hat\eta^{r-1}| \leq \epsilon\hat\eta^{r-1}$, so that

$$\lambda_E^\partial B(y,\delta) \geq \lambda_E^\partial B(y,\hat\eta) \geq (\beta_{r-1} - \epsilon)\hat\eta^{r-1} \geq (\beta_{r-1} - \epsilon)(1+\epsilon)^{1-r}\delta^{r-1}.$$

Thus, for every $\delta \in]0, \delta_0]$,

$$(\beta_{r-1} - \epsilon)(1+\epsilon)^{1-r}\delta^{r-1} \leq \lambda_E^\partial B(y,\delta) \leq (\beta_{r-1} + \epsilon)(1+\epsilon)^{r-1}\delta^{r-1}.$$

As ϵ is arbitrary,

$$\lim_{\delta \downarrow 0} \frac{\lambda_E^\partial B(y,\delta)}{\delta^{r-1}} = \beta_{r-1},$$

as claimed.

474S The Compactness Theorem Let Σ be the algebra of Lebesgue measurable subsets of $\mathbb{R}^r$, and give it the topology $\mathfrak{T}_m$ of convergence in measure defined by the pseudometrics $\rho_H(E,F) = \mu((E \triangle F) \cap H)$ for measurable sets H of finite measure (cf. §§245 and 323). Then

(a) $\mathrm{per} : \Sigma \to [0,\infty]$ is lower semi-continuous.

(b) For any $\gamma < \infty$, $\{E : E \in \Sigma, \mathrm{per}\, E \leq \gamma\}$ is compact.

proof (a) Let $\langle E_n \rangle_{n \in \mathbb{N}}$ be any $\mathfrak{T}_m$-convergent sequence in Σ with limit $E \in \Sigma$. If $\phi : \mathbb{R}^r \to B(\mathbf{0}, 1)$ is a Lipschitz function with compact support, then $\mathrm{div}\, \phi$ is integrable, so $F \mapsto \int_F \mathrm{div}\, \phi\, d\mu$ is truly continuous (225A), and

$$|\int_E \operatorname{div}\phi\, d\mu| = \lim_{n\to\infty} |\int_{E_n} \operatorname{div}\phi\, d\mu| \le \sup_{n\in\mathbb{N}} \operatorname{per} E_n.$$

As ϕ is arbitrary, $\operatorname{per} E \le \sup_{n\in\mathbb{N}} \operatorname{per} E_n$. This means that $\{E : \operatorname{per} E \le \gamma\}$ is sequentially closed, therefore closed (4A2Ld), for any γ, and per is lower semi-continuous.

(b) Set $\mathcal{A} = \{E : \operatorname{per} E \le \gamma\}$. Let us say that a 'dyadic cube' is a set expressible in the form $D = \prod_{i<r} [2^{-n}k_i, 2^{-n}(k_i+1)[$ where n, $k_0, \dots, k_{r-1} \in \mathbb{Z}$.

(i) For $E \in \mathcal{A}$, $n \in \mathbb{N}$ and $\epsilon \in]0,1]$ let $G(E,n,\epsilon)$ be the union of all the dyadic cubes D with side length 2^{-n} such that $\epsilon\mu D \le \mu(E\cap D) \le (1-\epsilon)\mu D$. Then $\mu G(E,n,\epsilon) \le \frac{c_1}{2^n\epsilon}\gamma$, where $c_1 = 2^{r+3}(1+2^{r+1})(1+\sqrt{r})^{r+1}$.

P Express $G(E,n,\epsilon)$ as a disjoint union $\bigcup_{i<k} D_i$ where each D_i is a dyadic cube of side length 2^{-n} and $\min(\mu(D_i\cap E), \mu(D_i\setminus E)) \ge \epsilon\mu D_i$. Let x_i be the centre of D_i and B_i the ball $B(x_i, 2^{-n-1}\sqrt{r})$, so that $D_i \subseteq B_i$ and $\mu B_i = \beta_r(\frac{1}{2}\sqrt{r})^r \mu D_i$. For any $x \in \mathbb{R}^r$, the ball $B(x, 2^{-n-1}\sqrt{r})$ is included in a closed cube with side length $2^{-n}\sqrt{r}$, so can contain at the very most $(1+\sqrt{r})^r$ different x_i, because different x_i differ by at least 2^{-n} in some coordinate. Turning this round, $\sum_{i=0}^{k-1} \chi B_i \le (1+\sqrt{r})^r \chi(\mathbb{R}^r)$.

Set $c = 2^{r+2}(1+\sqrt{r})(1+2^{r+1})$. Then, for each $i<k$,

$$\begin{aligned} 2c\lambda_E^\partial B_i &\ge \min(\mu(B_i\cap E), \mu(B_i\setminus E))^{(r-1)/r} \\ &\ge \min(\mu(D_i\cap E), \mu(D_i\setminus E))^{(r-1)/r} \ge (\epsilon\mu D_i)^{(r-1)/r} \ge 2^{-n(r-1)}\epsilon. \end{aligned}$$

((474Lb))

So

$$\begin{aligned} \mu G(E,n,\epsilon) = 2^{-nr}k &\le \frac{2c}{2^n\epsilon}\sum_{i=0}^{k} \lambda_E^\partial B_i \\ &\le \frac{2c(1+\sqrt{r})^r}{2^n\epsilon}\lambda_E^\partial(\mathbb{R}^r) = \frac{c_1}{2^n\epsilon}\gamma. \ \mathbf{Q} \end{aligned}$$

(ii) Now let $\langle E_n\rangle_{n\in\mathbb{N}}$ be any sequence in $\mathcal{A}$. Then we can find a subsequence $\langle E_n'\rangle_{n\in\mathbb{N}}$ such that whenever $n \in \mathbb{N}$, D is a dyadic cube of side length 2^{-n} meeting $B(\mathbf{0},n)$, and i, $j \ge n$, then $|\mu(D\cap E_i') - \mu(D\cap E_j')| \le \frac{1}{(n+1)^{r+2}}\mu D$. Now

$$\mu((E_i'\triangle E_j')\cap B(\mathbf{0},n)) \le \frac{3\beta_r(n+\sqrt{r})^r}{(n+1)^{r+2}} + 2^{-n}(n+1)^{r+1}c_1\gamma$$

whenever $n \ge 1$ and i, $j \ge n$. **P** Let $\mathcal{E}$ be the set of dyadic cubes of side length 2^{-n} meeting $B(\mathbf{0},n)$; then every member of $\mathcal{E}$ is included in $B(\mathbf{0}, n+2^{-n}\sqrt{r})$, so $\mu(\bigcup\mathcal{E}) \le \beta_r(n+\sqrt{r})^r$. Let $\mathcal{E}_1$ be the collection of those dyadic cubes of side length 2^{-n} included in $G(E_i', n, \frac{1}{(n+1)^{r+2}})$. If $D \in \mathcal{E}\setminus\mathcal{E}_1$, either $\mu(E_i'\cap D) \le \frac{1}{(n+1)^{r+2}}\mu D$ and $\mu(E_j'\cap D) \le \frac{2}{(n+1)^{r+2}}\mu D$ and $\mu((E_i'\triangle E_j')\cap D) \le \frac{3}{(n+1)^{r+2}}\mu D$, or $\mu(D\setminus E_i') \le \frac{1}{(n+1)^{r+2}}\mu D$ and $\mu(D\setminus E_j') \le \frac{2}{(n+1)^{r+2}}\mu D$ and $\mu((E_i'\triangle E_j')\cap D) \le \frac{3}{(n+1)^{r+2}}\mu D$. So

$$\begin{aligned} \mu((E_i'\triangle E_j')\cap B(\mathbf{0},n)) &\le \sum_{D\in\mathcal{E}} \mu((E_i'\triangle E_j')\cap D) \\ &\le \sum_{D\in\mathcal{E}\setminus\mathcal{E}_1} \mu((E_i'\triangle E_j')\cap D) + \mu(\bigcup\mathcal{E}_1) \\ &\le \frac{3}{(n+1)^{r+2}}\mu(\bigcup\mathcal{E}) + \mu G(E_i', n, \frac{1}{(n+1)^{r+2}}) \\ &\le \frac{3\beta_r(n+\sqrt{r})^r}{(n+2)^{r+1}} + 2^{-n}(n+1)^{r+2}c_1\gamma, \end{aligned}$$

as claimed. **Q**

(iii) This means that $\sum_{i=0}^{\infty} \mu((E_i' \triangle E_{i+1}') \cap B(\mathbf{0},n))$ is finite for each $n \in \mathbb{N}$, so that if we set $E = \bigcup_{i\in\mathbb{N}} \bigcap_{j\geq i} E_j'$, then

$$\mu((E\triangle E_i') \cap B(\mathbf{0},n)) \leq \sum_{j=i}^{\infty} \mu((E_j' \triangle E_{j+1}') \cap B(\mathbf{0},n)) \to 0$$

as $i \to \infty$ for every $n \in \mathbb{N}$. It follows that $\lim_{i\to\infty} \rho_H(E, E_i') = 0$ whenever $\mu H < \infty$ (see the proofs of 245Eb and 323Gb). Thus we have a subsequence $\langle E_i' \rangle_{i\in\mathbb{N}}$ of the original sequence $\langle E_i \rangle_{i\in\mathbb{N}}$ which is convergent for the topology $\mathfrak{T}_m$ of convergence in measure. By (a), its limit belongs to $\mathcal{A}$. But since $\mathfrak{T}_m$ is pseudometrizable (245Eb/323Gb), this is enough to show that A is compact for $\mathfrak{T}_m$ (4A2Lf).

474X Basic exercises (a) Show directly from 474E that if $E \subseteq \mathbb{R}^r$ has locally finite perimeter and $F \subseteq \mathbb{R}^r$ is such that $\mu(E\triangle F) = 0$, then F has locally finite perimeter, $\lambda_F^\partial = \lambda_E^\partial$, and any outward-normal function for E is an outward-normal function for F.

(b) Show that for any $E \subseteq \mathbb{R}^r$ with locally finite perimeter, its reduced boundary is a Borel set.

(c) Show that if $E \subseteq \mathbb{R}^r$ has locally finite perimeter, then $\partial^{\$} E \subseteq \partial E$. (*Hint*: 474N(i)-(ii).)

(d) Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter, and $y \in \partial^{\$} E$. Show that $\lim_{\delta\downarrow 0} \frac{\mu(E\cap B(y,\delta))}{\mu B(y,\delta)} = \frac{1}{2}$.

(e) In the proof of 474R, use 265E to show that

$$\int_{H\cap\partial B(y,\delta)} v \bullet \tfrac{1}{\delta}(x-y)\nu(dx) = -\beta_{r-1}\delta^{r-1}$$

for *every* $\delta > 0$.

474Y Further exercises (a) In 474E, explain how to interpret the pair $(\psi, \lambda_E^\partial)$ as a vector measure (definition: 393O) $\theta_E : \mathcal{B} \to \mathbb{R}^r$, where $\mathcal{B}$ is the Borel σ-algebra of $\mathbb{R}^r$, in such a way that we have $\int_E \operatorname{div}\phi\, d\mu = \int \phi\, d\theta_E$ for Lipschitz functions ϕ with compact support.

474 Notes and comments When we come to the Divergence Theorem itself in the next section, it will be nothing but a repetition of Theorem 474E with the perimeter measure and the outward-normal function properly identified. The idea of the indirect approach here is to start by defining the pair $(\psi_E, \lambda_E^\partial)$ as a kind of 'distributional derivative' of the set E. I take the space to match the details with the language of the rest of this treatise, but really 474E amounts to nothing more than the Riesz representation theorem; since the functional $\phi \mapsto \int_E \operatorname{div}\phi\, d\mu$ is linear, and we restrict attention to sets E for which it is continuous in an appropriate sense (and can therefore be extended to arbitrary continuous functions ϕ with compact support), it must be representable by a (vector) measure, as in 474Ya. For the process to be interesting, we have to be able to identify at least some of the appropriate sets E with their perimeter measures and outward-normal functions. Half-spaces are straightforward enough (474I), and 474Q tells us what the outward-normal functions have to be; but for a proper description of the family of sets with locally finite perimeter we must wait until the next section. I see no quick way to show from the results here that (for instance) the union of two sets with finite perimeter again has finite perimeter.

I have tried to find the shortest path to the Divergence Theorem itself, and have not attempted to give 'best' results in the intermediate material. In particular, in the isoperimetric inequality 474La, I show only that the measure of a set E is controlled by the magnitude of its perimeter measure. Simple scaling arguments show that if there is any such control, then it must be of the form $\gamma(\mu E)^{(r-1)/r} \leq \operatorname{per} E$; the identification of the best constant γ as $r\beta_r^{1/r}$, giving equality for balls, is the real prize, to which I shall come in 476L.

I leave the Compactness Theorem (474S) to the end of the section because it is off the line I have chosen to the Divergence Theorem (though it can be used to make the proof of 474Q more transparent; see Evans & Gariepy 92, 5.7.2). I have expressed 474S in terms of the topology of convergence in measure on the algebra of Lebesgue measurable sets. But since the perimeter of a measurable set E is not altered if we

change E by a negligible set, 'perimeter' can equally well be regarded as a function defined on the measure algebra, in which case 474S becomes a theorem about the usual topology of the measure algebra of Lebesgue measure, as described in §323.

475 The essential boundary

The principal aim of this section is to translate Theorem 474E into geometric terms. We have already identified the Federer exterior normal as an outward-normal function (474Q), so we need to find a description of perimeter measures. Most remarkably, it turns out that these are nothing but simple indefinite-integral measures over normalized Hausdorff measures (475G). This description needs the concept of 'essential boundary' (475B). In order to complete the programme, we need to be able to determine which sets have 'locally finite perimeter'; there is a natural criterion in the same language (475L). We now have all the machinery for a direct statement of the Divergence Theorem (for Lipschitz functions) which depends on nothing more advanced than the definition of Hausdorff measure (475N). (The definitions, at least, of 'Federer exterior normal' and 'essential boundary' are elementary.)

This concludes the main work of the middle part of this chapter. But since we are now within reach of a reasonably direct proof of a fundamental fact about the $r-1$-dimensional Hausdorff measure of the boundaries of subsets of $\mathbb{R}^r$ (475Q), I continue up to Cauchy's Perimeter Theorem and the Isoperimetric Theorem for convex sets (475S, 475T).

475A Notation As in the last two sections, r will be an integer (greater than or equal to 2, unless explicitly permitted to take the value 1). μ will be Lebesgue measure on $\mathbb{R}^r$; I will sometimes write μ_{r-1} for Lebesgue measure on $\mathbb{R}^{r-1}$ and μ_1 for Lebesgue measure on $\mathbb{R}$. $\beta_r = \mu B(\mathbf{0},1)$ will be the measure of the unit ball in $\mathbb{R}^r$, and $S_{r-1} = \partial B(\mathbf{0},1)$ will be the unit sphere. ν will be normalized $r-1$-dimensional Hausdorff measure on $\mathbb{R}^r$ (265A), that is, $\nu = 2^{-r+1}\beta_{r-1}\mu_{H,r-1}$, where $\mu_{H,r-1}$ is $r-1$-dimensional Hausdorff measure on $\mathbb{R}^r$. I will take it for granted that $x \in \mathbb{R}^r$ has coordinates $(\xi_1, \dots, \xi_r)$.

If $E \subseteq \mathbb{R}^r$ has locally finite perimeter (474D), λ_E^∂ will be its perimeter measure (474F), $\partial^\$ E$ its reduced boundary (474G) and ψ_E its canonical outward normal (474G).

475B The essential boundary (In this paragraph I allow $r = 1$.) Let $A \subseteq \mathbb{R}^r$ be any set. The **essential closure** of A is the set

$$\mathrm{cl}^*A = \{x : \limsup_{\delta \downarrow 0} \tfrac{\mu^*(B(x,\delta)\cap A)}{\mu B(x,\delta)} > 0\}.$$

Similarly, the **essential interior** of A is the set

$$\mathrm{int}^*A = \{x : \liminf_{\delta \downarrow 0} \tfrac{\mu_*(B(x,\delta)\cap A)}{\mu B(x,\delta)} = 1\}.$$

(If A is Lebesgue measurable, this is the lower Lebesgue density of A, as defined in 341E.) Finally, the **essential boundary** ∂^*A of A is the difference $\mathrm{cl}^*A \setminus \mathrm{int}^*A$.

475C Lemma (In this lemma I allow $r = 1$.) Let A, $A' \subseteq \mathbb{R}^r$.

(a)

$$\mathrm{int}\, A \subseteq \mathrm{int}^*A \subseteq \mathrm{cl}^*A \subseteq \overline{A}, \quad \partial^*A \subseteq \partial A,$$

$$\mathrm{cl}^*A = \mathbb{R}^r \setminus \mathrm{int}^*(\mathbb{R}^r \setminus A), \quad \partial^*(\mathbb{R}^r \setminus A) = \partial^*A.$$

(b) If $A \setminus A'$ is negligible, then $\mathrm{cl}^*A \subseteq \mathrm{cl}^*A'$ and $\mathrm{int}^*A \subseteq \mathrm{int}^*A'$; in particular, if A itself is negligible, cl^*A, int^*A and ∂^*A are all empty.

(c) int^*A, cl^*A and ∂^*A are Borel sets.

(d) $\mathrm{cl}^*(A\cup A') = \mathrm{cl}^*A \cup \mathrm{cl}^*A'$ and $\mathrm{int}^*(A\cap A') = \mathrm{int}^*A \cap \mathrm{int}^*A'$, so $\partial^*(A\cup A')$, $\partial^*(A\cap A')$ and $\partial^*(A\triangle A')$ are all included in $\partial^*A \cup \partial^*A'$.

(e) $\mathrm{cl}^*A \cap \mathrm{int}^*A' \subseteq \mathrm{cl}^*(A\cap A')$, $\partial^*A \cap \mathrm{int}^*A' \subseteq \partial^*(A\cap A')$ and $\partial^*A \setminus \mathrm{cl}^*A' \subseteq \partial^*(A\cup A')$.

(f) $\partial^*(A\cap A') \subseteq (\mathrm{cl}^*A' \cap \partial A) \cup (A \cap \partial^*A')$.

(g) If $E \subseteq \mathbb{R}^r$ is Lebesgue measurable, then $E\triangle\mathrm{int}^*E$, $E\triangle\mathrm{cl}^*E$ and ∂^*E are Lebesgue negligible.

(h) A is Lebesgue measurable iff ∂^*A is Lebesgue negligible.

proof (a) It is obvious that

$$\operatorname{int} A \subseteq \operatorname{int}^*A \subseteq \operatorname{cl}^*A \subseteq \overline{A},$$

so that $\partial^*A \subseteq \partial A$. Since

$$\frac{\mu^*(B(x,\delta)\cap A)}{\mu B(x,\delta)} + \frac{\mu_*(B(x,\delta)\setminus A)}{\mu B(x,\delta)} = 1$$

for every $x \in \mathbb{R}^r$ and every $\delta > 0$ (413Ec), $\mathbb{R}^r \setminus \operatorname{int}^*A = \operatorname{cl}^*(\mathbb{R}^r \setminus A)$. It follows that

$$\begin{aligned}\partial^*(\mathbb{R}^r \setminus A) &= \operatorname{cl}^*(\mathbb{R}^r \setminus A) \triangle \operatorname{int}^*(\mathbb{R}^r \setminus A)\\ &= (\mathbb{R}^r \setminus \operatorname{int}^*A) \triangle (\mathbb{R}^r \setminus \operatorname{cl}^*A) = \operatorname{int}^*A \triangle \operatorname{cl}^*A = \partial^*A.\end{aligned}$$

(b) If $A \setminus A'$ is negligible, then

$$\mu_*(B(x,\delta)\cap A) \le \mu_*(B(x,\delta)\cap A'), \quad \mu^*(B(x,\delta)\cap A) \le \mu^*(B(x,\delta)\cap A')$$

for all x and δ, so $\operatorname{int}^*A \subseteq \operatorname{int}^*A'$ and $\operatorname{cl}^*A \subseteq \operatorname{cl}^*A'$.

(c) The point is just that $(x,\delta) \mapsto \mu^*(A \cap B(x,\delta))$ is continuous. **P** For any x, $y \in \mathbb{R}^r$ and δ, $\eta \ge 0$ we have

$$\begin{aligned}|\mu^*(A\cap B(y,\eta)) - \mu^*(A\cap B(x,\delta))| &\le \mu(B(y,\eta)\triangle B(x,\delta))\\ &= 2\mu(B(x,\delta)\cup B(y,\eta)) - \mu B(x,\delta) - \mu B(y,\eta)\\ &\le \beta_r\big(2(\max(\delta,\eta) + \|x-y\|)^r - \delta^r - \eta^r\big) \to 0\end{aligned}$$

as $(y,\eta) \to (x,\delta)$. **Q** So

$$x \mapsto \limsup_{\delta\downarrow 0} \frac{\mu^*(A\cap B(x,\delta))}{\mu B(x,\delta)} = \inf_{\alpha\in\mathbb{Q},\alpha>0} \sup_{\beta\in\mathbb{Q},0<\beta\le\alpha} \frac{1}{\beta_r\beta^r}\mu^*(A\cap B(x,\beta))$$

is Borel measurable, and

$$\operatorname{cl}^*A = \{x : \limsup_{\delta\downarrow 0} \frac{\mu^*(A\cap B(x,\delta))}{\mu B(x,\delta)} = 1\}$$

is a Borel set.

Accordingly $\operatorname{int}^*A = \mathbb{R}^r \setminus \operatorname{cl}^*(\mathbb{R}^r \setminus A)$ and ∂^*A are also Borel sets.

(d) For any $x \in \mathbb{R}^r$,

$$\begin{aligned}\limsup_{\delta\downarrow 0} \frac{\mu^*((A\cup A')\cap B(x,\delta))}{\mu B(x,\delta)} &\le \limsup_{\delta\downarrow 0} \frac{\mu^*(A\cap B(x,\delta))}{\mu B(x,\delta)} + \frac{\mu^*(A'\cap B(x,\delta))}{\mu B(x,\delta)}\\ &\le \limsup_{\delta\downarrow 0} \frac{\mu(A\cap B(x,\delta))}{\mu B(x,\delta)} + \limsup_{\delta\downarrow 0} \frac{\mu(A'\cap B(x,\delta))}{\mu B(x,\delta)},\end{aligned}$$

so $\operatorname{cl}^*(A\cup A') \subseteq \operatorname{cl}^*A \cup \operatorname{cl}^*A'$. Of course $\operatorname{cl}^*A \cup \operatorname{cl}^*A' \subseteq \operatorname{cl}^*(A\cup A')$, so we have equality. Accordingly

$$\operatorname{int}^*(A\cap A') = \mathbb{R}^r \setminus \operatorname{cl}^*((\mathbb{R}^r\setminus A)\cup(\mathbb{R}^r\setminus A')) = \operatorname{int}^*A \cap \operatorname{int}^*A'.$$

Since of course $\operatorname{int}^*(A\cup A') \supseteq \operatorname{int}^*A \cup \operatorname{int}^*A'$, $\partial^*(A\cup A') \subseteq \partial^*A \cup \partial^*A'$. Now

$$\partial^*(A\cap A') = \partial^*(\mathbb{R}^r\setminus(A\cap A')) \subseteq \partial^*(\mathbb{R}^r\setminus A)\cup\partial^*(\mathbb{R}^r\setminus A')) = \partial^*A\cup\partial^*A'$$

and

$$\partial^*(A\triangle A') \subseteq \partial^*(A\cap(\mathbb{R}^r\setminus A'))\cup\partial^*(A'\cap(\mathbb{R}^r\setminus A)) \subseteq \partial^*A\cup\partial^*A'.$$

(e) If $x \in \operatorname{cl}^*A \cap \operatorname{int}^*A'$, then $x \notin \operatorname{cl}^*(\mathbb{R}^r\setminus A')$ so $x \notin \operatorname{cl}^*(A\setminus A')$. But from (d) we know that $x \in \operatorname{cl}^*(A\cap A')\cup\operatorname{cl}^*(A\setminus A')$, so $x \in \operatorname{cl}^*(A\cap A')$.

Now

$$\begin{aligned}\partial^*A \cap \operatorname{int}^*A' &= (\operatorname{cl}^*A \cap \operatorname{int}^*A') \setminus \operatorname{int}^*A \\ &\subseteq \operatorname{cl}^*(A \cap A') \setminus \operatorname{int}^*(A \cap A') = \partial^*(A \cap A'),\end{aligned}$$

$$\begin{aligned}\partial^*A \setminus \operatorname{cl}^*A' &= \partial^*(\mathbb{R}^r \setminus A) \cap \operatorname{int}^*(\mathbb{R}^r \setminus A') \\ &\subseteq \partial^*((\mathbb{R}^r \setminus A) \cap (\mathbb{R}^r \setminus A')) \\ &= \partial^*(\mathbb{R}^r \setminus (A \cup A')) = \partial^*(A \cup A').\end{aligned}$$

(f) If $x \in \partial^*(A \cap A') \cap \partial A$, then of course $x \in \operatorname{cl}^*(A \cap A') \subseteq \operatorname{cl}^*A$, so $x \in \operatorname{cl}^*A \cap \partial A$. If $x \in \partial^*(A \cap A') \setminus \partial A$, then surely $x \in \overline{A}$, so $x \in \operatorname{int} A$. But this means that

$$\mu_*(B(x,\delta) \cap A') = \mu_*(B(x,\delta) \cap A \cap A'), \quad \mu^*(B(x,\delta) \cap A') = \mu^*(B(x,\delta) \cap A \cap A')$$

for all δ small enough, so $x \in \partial^*A'$ and $x \in A \cap \partial^*A'$.

(g) Applying 472D to μ and χE, we see that

$$\begin{aligned}\partial^*E &\subseteq (E \triangle \operatorname{cl}^*E) \cup (E \triangle \operatorname{int}^*E) \\ &\subseteq \{x : \chi E(x) \neq \lim_{\delta \downarrow 0} \tfrac{\mu(E \cap B(x,\delta))}{\mu B(x,\delta)}\}\end{aligned}$$

are all μ-negligible.

(h) If A is Lebesgue measurable then (g) tells us that ∂^*A is negligible. If ∂^*A is negligible, let E be a measurable envelope of A. Then $\mu(E \cap B(x,\delta)) = \mu^*(A \cap B(x,\delta))$ for all x and δ, so $\operatorname{cl}^*E = \operatorname{cl}^*A$. Similarly, if F is a measurable envelope of $\mathbb{R}^r \setminus A$, then $\operatorname{cl}^*F = \operatorname{cl}^*(\mathbb{R}^r \setminus A) = \mathbb{R}^r \setminus \operatorname{int}^*A$ (using (a)). Now (g) tells us that

$$\mu(E \cap F) = \mu(\operatorname{cl}^*E \cap \operatorname{cl}^*F) = \mu(\operatorname{cl}^*A \setminus \operatorname{int}^*A) = 0.$$

But now $A \setminus E$ and $E \setminus A \subseteq (E \cap F) \cup ((\mathbb{R}^r \setminus A) \setminus F)$ are Lebesgue negligible, so A is Lebesgue measurable.

475D Lemma Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter, and $\partial^{\$}E$ its reduced boundary (474G). Then $\partial^{\$}E \subseteq \partial^*E$ and $\nu(\partial^*E \setminus \partial^{\$}E) = 0$.

proof (a) By 474N(i), $\partial^{\$}E \subseteq \operatorname{cl}^*E$; by 474N(ii), $\partial^{\$}E \cap \operatorname{int}^*E = \emptyset$; so $\partial^{\$}E \subseteq \partial^*E$.

(b) For any $y \in \partial^*E$,

$$\limsup_{\delta \downarrow 0} \tfrac{1}{\delta^{r-1}} \lambda^{\partial}_E B(y,\delta) > 0.$$

P We have an $\epsilon \in \left]0, \frac{1}{2}\right]$ such that

$$\liminf_{\delta \downarrow 0} \tfrac{\mu(E \cap B(y,\delta))}{\mu B(y,\delta)} < 1 - \epsilon, \quad \limsup_{\delta \downarrow 0} \tfrac{\mu(E \cap B(y,\delta))}{\mu B(y,\delta)} > \epsilon.$$

Since the function $\delta \mapsto \frac{\mu(E \cap B(y,\delta))}{\mu B(y,\delta)}$ is continuous, there is a sequence $\langle \delta_n \rangle_{n \in \mathbb{N}}$ in $]0, \infty[$ such that $\lim_{n \to \infty} \delta_n = 0$ and

$$\epsilon \mu B(y,\delta_n) \leq \mu(E \cap B(y,\delta_n)) \leq (1-\epsilon)\mu B(y,\delta_n)$$

for every n. Now from 474Lb we have

$$\begin{aligned}(\epsilon\beta_r)^{(r-1)/r}\delta_n^{r-1} &= (\epsilon \mu B(y,\delta_n))^{(r-1)/r} \\ &\leq \min(\mu(B(y,\delta_n) \cap E), \mu(B(y,\delta_n) \setminus E))^{(r-1)/r} \leq 2c\lambda^{\partial}_E B(y,\delta_n)\end{aligned}$$

for every n, where c is the constant there. But this means that

$$\limsup_{\delta \downarrow 0} \tfrac{1}{\delta^{r-1}} \lambda^{\partial}_E B(y,\delta) \geq \limsup_{n \to \infty} \tfrac{1}{\delta_n^{r-1}} \lambda^{\partial}_E B(y,\delta_n) \geq \tfrac{1}{2c}(\epsilon\beta_r)^{(r-1)/r} > 0. \quad \textbf{Q}$$

(c) Let $\epsilon > 0$. Set

$$F_\epsilon = \{y : y \in \mathbb{R}^r \setminus \partial^{\$} E, \limsup_{\delta \downarrow 0} \frac{1}{\delta^{r-1}} \lambda_E^\partial B(y,\delta) > \epsilon\}.$$

Because $\partial^{\$} E$ is λ_E^∂-conegligible (474G), $\lambda_E^\partial F_\epsilon = 0$. So there is an open set $G \supseteq F_\epsilon$ such that $\lambda_E^\partial G \leq \epsilon^2$ (256Bb). Let $\delta > 0$. Let $\mathcal{I}$ be the family of all those non-singleton closed balls $B \subseteq G$ such that $\operatorname{diam} B \leq \delta$ and $\lambda_E^\partial B \geq 2^{-r+1}\epsilon(\operatorname{diam} B)^{r-1}$. Then every point of F_ϵ is the centre of arbitrarily small members of $\mathcal{I}$. By Besicovitch's Covering Lemma (472B), there is a family $\langle \mathcal{I}_k \rangle_{k<5^r}$ of disjoint countable subsets of $\mathcal{I}$ such that $\mathcal{I}^* = \bigcup_{k<5^r} \bigcup \mathcal{I}_k$ covers F_ϵ. Now

$$\sum_{B\in\mathcal{I}^*} (\operatorname{diam} B)^{r-1} \leq \sum_{k<5^r} \sum_{B\in\mathcal{I}_k} \frac{2^{r-1}}{\epsilon} \lambda_E^\partial B \leq \frac{5^r 2^{r-1}}{\epsilon} \lambda_E^\partial G \leq 5^r 2^{r-1}\epsilon.$$

As δ is arbitrary, $\mu^*_{H,r-1} F_\epsilon$ is at most $5^r 2^{r-1}\epsilon$ (264Fb/471Dc) and $\nu^* F_\epsilon \leq 5^r \beta_{r-1}\epsilon$. As ϵ is arbitrary,

$$\partial^* E \setminus \partial^{\$} E \subseteq \{y : y \in \mathbb{R}^r \setminus \partial^{\$} E, \limsup_{\delta\downarrow 0} \frac{1}{\delta^{r-1}} \lambda_E^\partial B(y,\delta) > 0\}$$

is ν-negligible, as claimed.

475E Lemma Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter.
(a) If $A \subseteq \partial^{\$} E$, then $\nu^* A \leq (\lambda_E^\partial)^* A$.
(b) If $A \subseteq \mathbb{R}^r$ and $\nu A = 0$, then $\lambda_E^\partial A = 0$.

proof (a) Given $\epsilon, \delta > 0$ let $\mathcal{I}$ be the family of non-trivial closed balls $B \subseteq \mathbb{R}^r$ of diameter at most δ such that $\beta_{r-1}(\frac{1}{2}\operatorname{diam} B)^{r-1} \leq (1+\epsilon)\lambda_E^\partial B$. By 474R, every point of A is the centre of arbitrarily small members of $\mathcal{I}$. By 472C, there is a countable family $\mathcal{I}_1 \subseteq I$ such that $A \subseteq \bigcup \mathcal{I}_1$ and $\sum_{B\in\mathcal{I}_1} \lambda_E^\partial B \leq (\lambda_E^\partial)^* A + \epsilon$. But this means that

$$\sum_{B\in\mathcal{I}_1} (\operatorname{diam} B)^{r-1} \leq (1+\epsilon)\frac{2^{r-1}}{\beta_{r-1}}((\lambda_E^\partial)^* A + \epsilon).$$

As δ is arbitrary,

$$\nu^* A = \frac{\beta_{r-1}}{2^{r-1}} \mu^*_{H,r-1} A \leq (1+\epsilon)((\lambda_E^\partial)^* A + \epsilon).$$

As ϵ is arbitrary, we have the result.

(b) For $n \in \mathbb{N}$, set

$$A_n = \{x : x \in A, \lambda_E^\partial B(x,\delta) \leq 2\beta_{r-1}\delta^{r-1} \text{ whenever } 0 < \delta \leq 2^{-n}\}.$$

Now, given $\epsilon > 0$, there is a sequence $\langle D_i \rangle_{i\in\mathbb{N}}$ of sets covering A_n such that $\operatorname{diam} D_i \leq 2^{-n}$ for every i and $\sum_{i=0}^\infty (\operatorname{diam} D_i)^{r-1} \leq \epsilon$. Passing over the trivial case $A_n = \emptyset$, we may suppose that for each $i \in \mathbb{N}$ there is an $x_i \in A_n \cap D_i$, so that $D_i \subseteq B(x_i, \operatorname{diam} D_i)$ and

$$\begin{aligned}(\lambda_E^\partial)^* A_n &\leq \sum_{i=0}^\infty (\lambda_E^\partial)^* D_i \leq \sum_{i=0}^\infty \lambda_E^\partial B(x_i, \operatorname{diam} D_i) \\ &\leq \sum_{i=0}^\infty 2\beta_{r-1}(\operatorname{diam} D_i)^{r-1} \leq 2\beta_{r-1}\epsilon.\end{aligned}$$

As ϵ is arbitrary, $\lambda_E^\partial A_n = 0$. And this is true for every n. As $A \setminus \bigcup_{n\in\mathbb{N}} A_n$ is λ_E^∂-negligible, by 474G and 474R, so is A.

475F Lemma Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter, and $\epsilon > 0$. Then λ_E^∂ is inner regular with respect to the family $\mathcal{E} = \{F : F \subseteq \mathbb{R}^r \text{ is Borel}, \lambda_E^\partial F \leq (1+\epsilon)\nu F\}$.

proof (a) We need some elementary bits of geometry.

(i) If $x \in \mathbb{R}^r$, $\delta > 0$, $\alpha \geq 0$ and $v \in S_{r-1}$, then

$$\mu\{z : z \in B(x,\delta),\ |(z-x)\boldsymbol{.}v| \leq \alpha\} \leq 2\alpha\beta_{r-1}\delta^{r-1}.$$

P Translating and rotating, if necessary, we can reduce to the case $x = \mathbf{0}$, $v = (0,\dots,1)$. In this case we are looking at

$$\{z : \|z\| \leq \delta,\ |\zeta_r| \leq \alpha\} \subseteq \{u : u \in \mathbb{R}^{r-1},\ \|u\| \leq \delta\} \times [-\alpha,\alpha]$$

which has measure $2\alpha\beta_{r-1}\delta^{r-1}$. **Q**

(ii) If $x \in \mathbb{R}^r$, $\delta > 0$, $0 < \eta \leq \frac{1}{2}$, $v \in S_{r-1}$, $H = \{z : z\boldsymbol{.}v \leq \alpha\}$ and

$$|\mu(H \cap B(x,\delta)) - \tfrac{1}{2}\mu B(x,\delta)| < 2^{-r+1}\beta_{r-1}\eta\delta^r,$$

then $|x\boldsymbol{.}v - \alpha| \leq \eta\delta$. **P** Again translating and rotating if necessary, we may suppose that $x = \mathbf{0}$ and $v = (0,\dots,1)$. Set $H_0 = \{z : \zeta_r \leq 0\}$. **?** If $\alpha > \eta\delta$, then $H \cap B(\mathbf{0},\delta)$ includes

$$H_0 \cap B(\mathbf{0},\delta) \cup \{u : u \in \mathbb{R}^{r-1},\ \|u\| \leq \tfrac{1}{2}\delta\} \times [0,\alpha],$$

so

$$\begin{aligned}\mu(H \cap B(\mathbf{0},\delta)) - \tfrac{1}{2}\mu B(\mathbf{0},\delta) &= \mu(H \cap B(\mathbf{0},\delta)) - \mu(H_0 \cap B(\mathbf{0},\delta))\\ &\geq 2^{-r+1}\beta_{r-1}\delta^{r-1}\alpha > 2^{-r+1}\beta_{r-1}\delta^r\eta,\end{aligned}$$

contrary to hypothesis. **X** Similarly, if $\alpha < -\eta\delta$, then $H \cap B(\mathbf{0},\delta)$ is included in

$$H_0 \cap B(\mathbf{0},\delta) \setminus \{u : u \in \mathbb{R}^{r-1},\ \|u\| \leq \tfrac{1}{2}\delta\} \times]\alpha,0],$$

so

$$\begin{aligned}\tfrac{1}{2}\mu B(\mathbf{0},\delta) - \mu(H \cap B(\mathbf{0},\delta)) &= \mu(H_0 \cap B(\mathbf{0},\delta)) - \mu(H \cap B(\mathbf{0},\delta))\\ &\geq 2^{-r+1}\beta_{r-1}\delta^{r-1}|\alpha| > 2^{-r+1}\beta_{r-1}\delta^r\eta,\end{aligned}$$

which is equally impossible. So $|\alpha| \leq \eta\delta$. **Q**

(b) Let F be such that $\lambda_E^\partial F > 0$. Let η, $\zeta > 0$ be such that

$$\eta < 1, \quad \tfrac{(1+\eta)^2}{(1-\eta)^{r-1}} \leq 1+\epsilon, \quad 2(1+2^r)\beta_r\zeta < 2^{-r}\beta_{r-1}\eta.$$

Because $\partial^\$E$ is λ_E^∂-conegligible (474G), $\lambda_E^\partial(F \cap \partial^\$E) > 0$. Because λ_E^∂ is a Radon measure (474E) and $\psi_E : \partial^\$E \to S_{r-1}$ is $\mathrm{dom}(\lambda_E^\partial)$-measurable (474G), there is a compact set $K_1 \subseteq F \cap \partial^\$E$ such that $\lambda_E^\partial K_1 > 0$ and $\psi_E\restriction K_1$ is continuous, by Lusin's theorem (418J). For $x \in \partial^\$E$, set $H_x = \{z : (z-x)\boldsymbol{.}\psi_E(x) \leq 0\}$. The function

$$(x,\delta) \mapsto \mu((E \triangle H_x) \cap B(x,\delta)) : K_1 \times [0,\infty[\to \mathbb{R}$$

is Borel measurable. **P** Take a Borel set E' such that $\mu(E \triangle E') = 0$. Then

$$\{(x,\delta,z) : x \in K_1,\ z \in (E' \triangle H_x) \cap B(x,\delta)\}$$

is a Borel set in $\mathbb{R}^r \times [0,\infty[\times \mathbb{R}^r$, so its sectional measure is a Borel measurable function, by 252P. **Q**

For each $x \in K_1$,

$$\lim_{n\to\infty} \tfrac{\mu((E\triangle H_x)\cap B(x,2^{-n}))}{\mu B(x,2^{-n})} = 0$$

(474P). So there is an $n_0 \in \mathbb{N}$ such that $\lambda_E^\partial F_1 > 0$, where F_1 is the Borel set

$$\{x : x \in K_1,\ \mu((E \triangle H_x) \cap B(x,2^{-n})) \leq \zeta\mu B(x,2^{-n}) \text{ for every } n \geq n_0\}.$$

Let $K_2 \subseteq F_1$ be a compact set such that $\lambda_E^\partial K_2 > 0$.

For each $n \in \mathbb{N}$, the function

$$x \mapsto \lambda_E^\partial B(x,2^{-n})) = \lambda_E^\partial(x + B(\mathbf{0},2^{-n})$$

is Borel measurable (444Fe). Let $y \in K_2$ be such that $\lambda_E^\partial(K_2 \cap B(y,\delta)) > 0$ for every $\delta > 0$ (cf. 411Nd). Set $v = \psi_E(y)$. Let $n \geq n_0$ be so large that $2\beta_{r-1}\|\psi_E(x) - v\| \leq \beta_r\zeta$ whenever $x \in K_1$ and $\|x - y\| \leq 2^{-n}$.

(c) We have $|(x-z)\cdot v| \leq \eta\|x-z\|$ whenever $x,\ z \in K_2 \cap B(y, 2^{-n-1})$. **P** If $x = z$ this is trivial. Otherwise, let $k \geq n$ be such that $2^{-k-1} \leq \|x-z\| \leq 2^{-k}$, and set $\delta = 2^{-k}$. Set

$$H'_x = \{w : (w-x)\cdot v \leq 0\}, \quad H'_z = \{w : (w-z)\cdot v \leq 0\}.$$

Since $|(w-x)\cdot v - (w-x)\cdot\psi_E(x)| \leq 2\delta\|\psi_E(x) - v\|$ whenever $w \in B(x, 2\delta)$,

$$(H_x \triangle H'_x) \cap B(x,2\delta) \subseteq \{w : w \in B(x,2\delta),\ |(w-x)\cdot v| \leq 2\delta\|\psi_E(x) - v\|\}$$

has measure at most

$$4\delta\|\psi_E(x) - v\|\beta_{r-1}(2\delta)^{r-1} \leq 2\delta\beta_r\zeta(2\delta)^{r-1} = \zeta\mu B(x,2\delta),$$

by (a-i). So

$$\begin{aligned}\mu((E\triangle H'_x)\cap B(x,2\delta)) &\leq \mu((E\triangle H_x)\cap B(x,2\delta)) + \mu((H_x\triangle H'_x)\cap B(x,2\delta))\\ &\leq 2\zeta\mu B(x,2\delta)\end{aligned}$$

because $k \geq n_0$ and $x \in F_1$. Similarly, $\mu((E\triangle H'_z)\cap B(z,\delta)) \leq 2\zeta\mu B(z,\delta)$. Now observe that because $\|x-z\| \leq \delta$, $B(z,\delta) \subseteq B(x,2\delta)$ and

$$\mu((E\triangle H'_x)\cap B(z,\delta)) \leq 2\zeta\mu B(x,2\delta) = 2^{r+1}\zeta\mu B(z,\delta),$$

and

$$\begin{aligned}\mu((H'_x\triangle H'_z)\cap B(z,\delta)) &\leq \mu((E\triangle H'_x)\cap B(z,\delta)) + \mu((E\triangle H'_z)\cap B(z,\delta))\\ &\leq (2+2^{r+1})\zeta\mu B(z,\delta).\end{aligned}$$

Since $\mu(H'_z \cap B(z,\delta)) = \frac{1}{2}\mu B(z,\delta)$,

$$|\mu(H'_x\cap B(z,\delta)) - \tfrac{1}{2}\mu B(z,\delta)| \leq 2(1+2^r)\zeta\mu B(z,\delta) < 2^{-r}\beta_{r-1}\eta\delta^r,$$

and (using (a-ii) above)

$$|(x-z)\cdot v| \leq \tfrac{1}{2}\eta\delta \leq \eta\|x-v\|. \ \textbf{Q}$$

(d) Let V be the hyperplane $\{w : w\cdot v = 0\}$, and let $T : K_2 \to V$ be the orthogonal projection, that is, $T(x) = x - (x\cdot v)v$ for every $x \in K_2$. Then (c) tells us that if $x,\ z \in F_1$,

$$\|T(x) - T(z)\| \geq \|x-z\| - |(x-z)\cdot v| \geq (1-\eta)\|x-z\|.$$

Because $\eta < 1$, T is injective. Consider the compact set $T[K_2]$. The inverse T^{-1} of T is $\frac{1}{1-\eta}$-Lipschitz, and $\nu K_2 > 0$ (by 475Eb), so $\nu T[K_2] \geq \frac{1}{(1-\eta)^{r-1}}\nu F_1 > 0$ (264G/471J). Let $G \supseteq T[K_2]$ be an open set such that $\nu(G\cap V) \leq (1+\eta)\nu T[K_2]$. (I am using the fact that the subspace measure ν_V induced by ν on V is a copy of Lebesgue measure on $\mathbb{R}^{r-1}$, so is a Radon measure.) Let $\mathcal{I}$ be the family of non-trivial closed balls $B \subseteq G$ such that $(1-\eta)^{r-1}\lambda_E^\partial T^{-1}[B] \leq (1+\eta)\nu(B\cap V)$. Then every point of $T[K_2]$ is the centre of arbitrarily small members of $\mathcal{I}$. **P** If $x \in K_2$ and $\delta_0 > 0$, there is a $\delta \in]0,\delta_0]$ such that $B(T(x),\delta) \subseteq G$ and $\lambda_E^\partial B(x,\delta) \leq (1+\eta)\beta_{r-1}\delta^{r-1}$ (474R). Now consider $B = B(T(x),(1-\eta)\delta)$. Then $T^{-1}[B] \subseteq B(x,\delta)$, so

$$\lambda_E^\partial T^{-1}[B] \leq \lambda_E^\partial B(x,\delta) \leq (1+\eta)\beta_{r-1}\delta^{r-1} = \frac{1+\eta}{(1-\eta)^{r-1}}\nu(B\cap V). \ \textbf{Q}$$

By 261B/472C, applied in $V \cong \mathbb{R}^{r-1}$, there is a countable disjoint family $\mathcal{I}_0 \subseteq \mathcal{I}$ such that $\nu(T[K_2] \setminus \bigcup\mathcal{I}_0) = 0$.

Now $\nu(K_2 \setminus \bigcup_{B\in\mathcal{I}_0} T^{-1}[B]) = 0$, because T^{-1} is Lipschitz, so $\lambda_E^\partial(K_2 \setminus \bigcup_{B\in\mathcal{I}_0} T^{-1}[B]) = 0$ (475Eb again), and

$$\lambda_E^\partial K_2 \le \sum_{B\in\mathcal{I}_0} \lambda_E^\partial T^{-1}[B] \le \frac{1+\eta}{(1-\eta)^{r-1}} \sum_{B\in\mathcal{I}_0} \nu(B\cap V)$$
$$\le \frac{1+\eta}{(1-\eta)^{r-1}}\nu(G\cap V) \le \frac{(1+\eta)^2}{(1-\eta)^{r-1}}\nu T[K_2] \le \frac{(1+\eta)^2}{(1-\eta)^{r-1}}\nu K_2$$

(because T is 1-Lipschitz)

$$\le (1+\epsilon)\nu K_2$$

by the choice of η. Thus $K_2 \in \mathcal{E}$.

(e) This shows that every non-negligible set measured by λ_E^∂ includes a non-negligible member of $\mathcal{E}$. As $\mathcal{E}$ is closed under disjoint unions, λ_E^∂ is inner regular with respect to $\mathcal{E}$ (412Aa).

475G Theorem Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter. Then $\lambda_E^\partial = \nu\llcorner\partial^*E$, that is, for $F \subseteq \mathbb{R}^r$, $\lambda_E^\partial F = \nu(F\cap\partial^*E)$ whenever either is defined.

proof (a) Suppose first that F is a Borel set included in the reduced boundary $\partial^\$E$ of E. Then $\nu F \le \lambda_E^\partial F$, by 475Ea. On the other hand, for any $\epsilon > 0$ and $\gamma < \lambda_E^\partial F$, there is an $F_1 \subseteq F$ such that

$$\gamma \le \lambda_E^\partial F_1 \le (1+\epsilon)\nu F_1 \le (1+\epsilon)\nu F,$$

by 475F; so we must have $\lambda_E^\partial F = \nu F$.

(b) Now suppose that F is measured by $\lambda_E^\partial F$. Because $\partial^\$E$ is λ_E^∂-conegligible, and λ_E^∂ is a σ-finite Radon measure, there is a Borel set $F' \subseteq F\cap\partial^\$E$ such that $\lambda_E^\partial(F\setminus F') = 0$. Now $\nu F' = \lambda_E^\partial F'$, by (a), and $\nu(F\cap\partial^\$E\setminus F') = 0$, by 475Ea, and $\nu(\partial^*E\setminus\partial^\$E) = 0$, by 475D; so $\nu(F\cap\partial^*E)$ is defined and equal to $\lambda_E^\partial F$.

(c) Let $\langle K_n\rangle_{n\in\mathbb{N}}$ be a non-decreasing sequence of compact subsets of $\partial^\$E$ such that $\bigcup_{n\in\mathbb{N}} K_n$ is λ_E^∂-conegligible. By (b), $\nu(\partial^*E\setminus\bigcup_{n\in\mathbb{N}}K_n) = 0$, while $\nu K_n = \lambda_E^\partial K_n$ is finite for each n. For each n, the subspace measure ν_{K_n} on K_n is a multiple of Hausdorff $r-1$-dimensional measure on K_n (471E), so is a Radon measure (471Dh/471F), and so is $(\lambda_E^\partial)_{K_n}$; since, by (b), ν_{K_n} and $(\lambda_E^\partial)_{K_n}$ agree on the Borel subsets of K_n, they are actually identical. So if $F\subseteq\mathbb{R}^r$ is such that ν measures $F\cap\partial^*E$, λ_E^∂ will measure $F\cap K_n$ for every n, and therefore will measure F; so that in this case also $\lambda_E^\partial F = \nu(F\cap\partial^*E)$.

475H Proposition Let $V\subseteq\mathbb{R}^r$ be a hyperplane, and $T:\mathbb{R}^r\to V$ the orthogonal projection. Suppose that $A\subseteq\mathbb{R}^r$ is such that νA is defined and finite, and for $u\in V$ set

$$f(u) = \#(A\cap T^{-1}[\{u\}]) \text{ if this is finite,}$$
$$= \infty \text{ otherwise.}$$

Then $\int_V f(u)\nu(du)$ is defined and at most νA.

proof (a) Because ν is invariant under isometries, we can suppose that $V = \{x : \xi_r = 0\}$, so that $T(x) = (\xi_1,\dots,\xi_{r-1},0)$ for $x = (\xi_1,\dots,\xi_r)$. For m, $n\in\mathbb{N}$ and $u\in V$ set

$$f_{mn}(u) = \#(\{k : k\in\mathbb{Z},\ |k|\le 4^m,\ A\cap(\{u\}\times[2^{-m}k, 2^{-m}(k+1-2^{-n})[) \ne\emptyset\});$$

so that $f(u) = \lim_{m\to\infty}\lim_{n\to\infty} f_{mn}(u)$ for every $u\in V$.

(b) Suppose for the moment that A is actually a Borel set. Then $T[A\cap(\mathbb{R}^r\times[\alpha,\beta[)]$ is always analytic (423E, 423Bb), therefore measured by ν (432A), and every f_{mn} is measurable. Next, given m, $n\in\mathbb{N}$ and $\epsilon>0$, there is a sequence $\langle F_i\rangle_{i\in\mathbb{N}}$ of closed sets of diameter at most 2^{-m-n}, covering A, such that $\sum_{i=0}^\infty 2^{-r+1}\beta_{r-1}(\operatorname{diam}F_i)^{r-1} \le \nu A+\epsilon$. Now each $T[F_i]$ is a compact set of diameter at most $\operatorname{diam}F_i$, so $\nu T[F_i] \le 2^{-r+1}\beta_{r-1}(\operatorname{diam}F_i)^{r-1}$ (264H); and if we set $g = \sum_{i=0}^\infty \chi T[F_i]$, $f_{mn}\le g$ everywhere on V, so $\int f_{mn}d\nu \le \int g\,d\nu \le \nu A+\epsilon$. As ϵ is arbitary, $\int f_{mn}d\nu\le\nu A$. Accordingly

$$\int f d\nu = \lim_{m\to\infty}\lim_{n\to\infty}\int f_{mn}d\nu \le \nu A.$$

(c) In general, there are Borel sets E, F such that $E \setminus F \subseteq A \subseteq E$ and $\nu F = 0$, by 264Fc or 471Db. By (b),

$$\int \#(E \cap T^{-1}[\{u\}])\nu(du) \leq \nu E, \quad \int \#(F \cap T^{-1}[\{u\}])\nu(du) \leq \nu F = 0,$$

so $\int \#(A \cap T^{-1}[\{u\}])\nu(du)$ is defined and equal to $\int \#(E \cap T^{-1}[\{u\}])\nu(du) \leq \nu A$.

475I Lemma (In this lemma I allow $r = 1$.) Let $E \subseteq \mathbb{R}^r$ be a Lebesgue measurable set, and $\gamma < \mu E$. Then there is a compact set $K \subseteq E$ such that $\mu K \geq \gamma$ and $K = \text{cl}^*K$.

proof **(a)** Write $\mathcal{C}^*$ for the set of dyadic (half-open) cubes in $\mathbb{R}^r$, that is, sets expressible in the form $\prod_{i<r} [2^{-m}k_i, 2^{-m}(k_i+1)[$ where m, $k_0, \ldots, k_{r-1} \in \mathbb{Z}$. For $m \in \mathbb{N}$, $x \in \mathbb{R}^r$ write $C(x,m)$ for the dyadic cube with side of length 2^{-m} which contains x. Then, for any $A \subseteq \mathbb{R}^r$,

$$\lim_{m\to\infty} 2^{mr}\mu_*(A \cap C(x,m)) = 1$$

for every $x \in \text{int}^*A$. **P** $C(x,m) \subseteq B(x, 2^{-m}\sqrt{r})$ for each m, so

$$2^{mr}\mu^*(C(x,m) \setminus A) \leq \beta_r r^{r/2} \frac{\mu(B(x,2^{-m}\sqrt{r}) \setminus A)}{\mu B(x,2^{-m}\sqrt{r})} \to 0$$

as $m \to \infty$. **Q**

(b) Now, given $\gamma < \mu E$, choose $\langle E_n\rangle_{n\in\mathbb{N}}$, $\langle \gamma_n\rangle_{n\in\mathbb{N}}$, $\langle m_n\rangle_{n\in\mathbb{N}}$ and $\langle K_n\rangle_{n\in\mathbb{N}}$ inductively, as follows. Start with $E_0 = E$ and $\gamma_0 = \gamma$. Given that $\gamma_n < \mu E_n$, let $K_n \subseteq E_n$ be a compact set of measure greater than γ_n. Now, by (a), there is an $m_n \geq n$ such that $\mu^* E_{n+1} > \gamma_n$, where

$$E_{n+1} = \{x : x \in K_n,\ \mu(K_n \cap C(x,m_n)) \geq \tfrac{2}{3}\mu C(x,m_n)\};$$

note that E_{n+1} is of the form $K_n \cap \bigcup \mathcal{D}$ for some set $\mathcal{D}$ of half-open cubes of side 2^{-m_n}, so that E_{n+1} is measurable and

$$\mu(E_{n+1} \cap C(x,m_n)) = \mu(K_n \cap C(x,m_n)) \geq \tfrac{2}{3}\mu C(x,m_n)$$

for every $x \in E_{n+1}$. Now set

$$\gamma_{n+1} = \max(\gamma_n, \mu E_{n+1} - \tfrac{1}{3}\cdot 2^{-m_n r}),$$

and continue.

At the end of the induction, set $K = \bigcap_{n\in\mathbb{N}} K_n = \bigcap_{n\in\mathbb{N}} E_n$. Then K is compact, $K \subseteq E$ and

$$\mu K = \lim_{n\to\infty} \mu K_n = \lim_{n\to\infty} \gamma_n \geq \gamma.$$

If $x \in K$ and $n \in \mathbb{N}$, then

$$\begin{aligned}\mu(K \cap B(x,2^{-m_n}\sqrt{r})) &\geq \mu(K \cap C(x,m_n)) \geq \mu(E_{n+1} \cap C(x,m_n)) - \mu E_{n+1} + \mu K\\ &\geq \tfrac{2}{3}\mu C(x,m_n) - \mu E_{n+1} + \gamma_{n+1}\\ &\geq \tfrac{1}{3}\cdot 2^{-m_n r} \geq \frac{1}{3\beta_r r^{r/2}}\mu B(x,2^{-m_n}\sqrt{r}),\end{aligned}$$

so

$$\limsup_{\delta\downarrow 0} \frac{\mu(K\cap B(x,\delta))}{\mu B(x,\delta)} \geq \frac{1}{3\beta_r r^{r/2}} > 0$$

and $x \in \text{cl}^*K$.

(c) Thus $K \subseteq \text{cl}^*K$. Since certainly $\text{cl}^*K \subseteq \overline{K} = K$, we have $K = \text{cl}^*K$.

475J Lemma Let E be a Lebesgue measurable subset of $\mathbb{R}^r$, identified with $\mathbb{R}^{r-1} \times \mathbb{R}$. For $u \in \mathbb{R}^{r-1}$, set $G_u = \{t : (u,t) \in \text{int}^*E\}$, $H_u = \{t : (u,t) \in \text{int}^*(\mathbb{R}^r \setminus E)\}$ and $D_u = \{t : (u,t) \in \partial^*E\}$, so that G_u, H_u and D_u are disjoint and cover $\mathbb{R}$.

(a) There is a μ_{r-1}-conegligible set $Z \subseteq \mathbb{R}^{r-1}$ such that whenever $u \in Z$, $t < t'$ in $\mathbb{R}$, $t \in G_u$ and $t' \in H_u$, there is an $s \in D_u \cap]t,t'[$.

(b) If E has locally finite perimeter, we can arrange further that, for every $u \in Z$, $D_u \cap [-n,n]$ is finite for every $n \in \mathbb{N}$, G_u and H_u are open, and $D_u = \partial G_u = \partial H_u$, so that the constituent intervals of $\mathbb{R} \setminus D_u$ lie alternately in G_u and H_u.

proof (a)(i) For $q \in \mathbb{Q}$, set $f_q(u) = \sup(G_u \cap]-\infty, q[)$, taking $-\infty$ for $\sup \emptyset$. Then $f : \mathbb{R}^{r-1} \to [-\infty, q]$ is Lebesgue measurable. **P** For $\alpha < q$,

$$\{u : f_q(u) > \alpha\} = \{u : \text{there is some } t \in]\alpha, q[\text{ such that } (u,t) \in \text{int}^*E\}.$$

Because int^*E is a Borel set (475Cc), $\{u : f_q(u) > \alpha\}$ is analytic (423E, 423Bc), therefore measurable (432A). **Q**

(ii) For any $q \in \mathbb{Q}$, $W_q = \{u : f_q(u) < q,\ f_q(u) \in G_u\}$ is negligible. **P?** Suppose, if possible, otherwise. Let $n \in \mathbb{N}$ be such that $\{u : u \in W_q,\ f_q(u) > -n\}$ is not negligible, and set $g(u) = \max(-n, f_q(u))$ for $u \in \mathbb{R}^{r-1}$. Then g is measurable, so by Lusin's theorem (418J) there is a Borel set $F \subseteq \mathbb{R}^{r-1}$ such that $g \restriction F$ is continuous and $F_1 = \{u : u \in F \cap W_q,\ f_q(u) \in G_u,\ f_q(u) > -n\}$ is not negligible. Note that F_1 is measurable, being the projection of the Borel set $\{(u, g(u)) : u \in F,\ -n < g(u) < q\} \cap \text{int}^*E$. By 475I, there is a non-negligible compact set $K \subseteq F_1$ such that $K \subseteq \text{cl}^*K$, interpreting cl^*K in $\mathbb{R}^{r-1}$. Because $g \restriction K$ is continuous, it attains its maximum at $u \in K$ say.

Set $x = (u, f_q(u))$. Then, whenever $0 < \delta \leq \min(n + f_q(u), q - f_q(u))$,

$$B(x, 2\delta) \setminus \text{int}^*E \supseteq \{(w,t) : w \in K \cap V(u,\delta),\ |t - f_q(u)| \leq \delta,\ f_q(w) < t < q\}$$

(writing $V(u,\delta)$ for $\{w : w \in \mathbb{R}^{r-1},\ \|w - u\| \leq \delta\}$)

$$\supseteq \{(w,t) : w \in K \cap V(u,\delta),\ f_q(u) < t \leq f_q(u) + \delta\}$$

because $f_q(w) = g(w) \leq g(u) = f_q(u)$ for every $w \in K$. So, for such δ,

$$\begin{aligned}\mu(B(x,2\delta) \setminus \text{int}^*E) &\geq \delta \mu_{r-1}(K \cap V(u,\delta)) \\ &= \frac{\beta_{r-1}}{2^r \beta_r} \cdot \frac{\mu_{r-1}(K \cap V(u,\delta))}{\mu_{r-1} V(u,\delta)} \cdot \mu B(x, 2\delta),\end{aligned}$$

and

$$\begin{aligned}\limsup_{\delta \downarrow 0} \frac{\mu(B(x,\delta) \setminus E)}{\mu B(x,\delta)} &= \limsup_{\delta \downarrow 0} \frac{\mu(B(x,2\delta) \setminus \text{int}^*E)}{\mu B(x,2\delta)} \\ &\geq \frac{\beta_{r-1}}{2^r \beta_r} \limsup_{\delta \downarrow 0} \frac{\mu_{r-1}(K \cap V(u,\delta))}{\mu_{r-1} V(u,\delta)} > 0\end{aligned}$$

because $u \in \text{cl}^*K$; but $x = (u, f_q(u))$ is supposed to belong to int^*E. **XQ**

(iii) Similarly, setting

$$f'_q(u) = \inf(H_u \cap]u, \infty[), \quad W'_q = \{u : q < f'_q(u) < \infty,\ f'_q(u) \in H_u\},$$

every W'_q is negligible. So $Z = \mathbb{R}^{r-1} \setminus \bigcup_{q \in \mathbb{Q}} (W_q \cup W'_q)$ is μ_{r-1}-conegligible.

Now if $u \in Z$, $t \in G_u$ and $t' \in H_u$, where $t < t'$, there is some $s \in]t,t'[\cap D_u$. **P?** Suppose, if possible, otherwise. Since, by hypothesis, neither t nor t' belongs to D_u, $D_u \cap [t,t'] = \emptyset$. Note that, because $u \in Z$,

$$s = \inf(G_u \cap]s, \infty[) \text{ for every } s \in G_u, \quad s = \sup(H_u \cap]-\infty, s[) \text{ for every } s \in H_u.$$

Choose $\langle s_n \rangle_{n \in \mathbb{N}}$, $\langle s'_n \rangle_{n \in \mathbb{N}}$ and $\langle \delta_n \rangle_{n \in \mathbb{N}}$ inductively, as follows. Set $s_0 = t$, $s'_0 = t'$. Given that $t \leq s_n < s'_n \leq t'$ and $s_n \in G_u$ and $s'_n \in H_u$, where n is even, set $s'_{n+1} = \sup(G_u \cap [s_n, s'_n])$. Then either $s'_{n+1} = s'_n$, so $s'_{n+1} \in H_u$, or $s'_{n+1} < s'_n$ and $\left]s'_{n+1}, s'_n\right] \cap G_u = \emptyset$, so $s'_{n+1} \notin G_u$ and again $s'_{n+1} \in H_u$. Let $\delta_n > 0$ be

such that $\delta_n \leq 2^{-n}$ and $\mu(E \cap B((u, s'_{n+1}), \delta_n)) < \frac{1}{2}\beta_r \delta_n^r$. Because the function $s \mapsto \mu(E \cap B((u, s), \delta_n))$ is continuous (443C, or otherwise), there is an $s_{n+1} \in G_u \cap \left[s_n, s'_{n+1}\right[$ such that $\mu(E \cap B((u, s), \delta_n)) \leq \frac{1}{2}\beta_r \delta_n^r$ whenever $s \in [s_{n+1}, s'_{n+1}]$.

This is the inductive step from even n. If n is odd and $s_n \in G_u$, $s'_n \in H_u$ and $s_n < s'_n$, set $s_{n+1} = \inf(H_u \cap [s_n, s'_n])$. This time we find that s_{n+1} must belong to G_u. Let $\delta_n \in]0, 2^{-n}]$ be such that $\mu(E \cap B((u, s_{n+1}), \delta_n)) > \frac{1}{2}\beta_r \delta_n^r$, and let $s'_{n+1} \in H_u \cap]s_{n+1}, s'_n]$ be such that $\mu(E \cap B((u, s), \delta_n)) \geq \frac{1}{2}\beta_r \delta_n^r$ whenever $s \in [s_{n+1}, s'_{n+1}]$.

The construction provides us with a non-increasing sequence $\langle [s_n, s'_n] \rangle_{n \in \mathbb{N}}$ of closed intervals, so there must be some s in their intersection. In this case

$$\mu(E \cap B((u, s), \delta_n) \leq \tfrac{1}{2}\beta_r \delta_n^r \text{ if } n \text{ is even},$$

$$\mu(E \cap B((u, s), \delta_n) \geq \tfrac{1}{2}\beta_r \delta_n^r \text{ if } n \text{ is odd}.$$

Since $\lim_{n \to \infty} \delta_n = 0$,

$$\liminf_{\delta \downarrow 0} \frac{\mu(E \cap B((u,s),\delta))}{\mu B((u,s),\delta)} \leq \frac{1}{2}, \quad \limsup_{\delta \downarrow 0} \frac{\mu(E \cap B((u,s),\delta))}{\mu B((u,s),\delta)} \geq \frac{1}{2},$$

and $s \in D_u$, while of course $t \leq s \leq t'$. **XQ**

(iv) Thus the conegligible set Z has the property required by (a).

(b) Now suppose that E has locally finite perimeter. Applying (a) to $\mathbb{R}^r \setminus E$, there is a conegligible set $Z_1 \subseteq \mathbb{R}^{r-1}$ such that if $u \in Z_1$, $t \in H_u$, $t' \in G_u$ and $t < t'$, then D_u meets $]t, t'[$. Next, we know that $\nu(\partial^* E \cap B(\mathbf{0}, n)) = \lambda_E^{\partial} B(\mathbf{0}, n)$ is finite for every $n \in \mathbb{N}$ (475G). By 475H,

$$\int_{\|u\| \leq n} \#(D_u \cap [-n, n]) \mu_{r-1}(du) \leq \nu(\partial^* E \cap B(\mathbf{0}, 2n)) < \infty$$

for every $n \in \mathbb{N}$; but this means that $D_u \cap [-n, n]$ must be finite for almost every u such that $\|u\| \leq n$, for every n, and therefore that

$$Z_2 = \{u : u \in Z \cap Z_1,\ D_u \cap [-n, n] \text{ is finite for every } n\}$$

is conegligible. For $u \in Z_2$, $\mathbb{R} \setminus D_u$ is an open set, so is made up of a disjoint sequence of intervals with endpoints in $D_u \cup \{-\infty, \infty\}$ (see 2A2I); and because $u \in Z \cap Z_1$, each of these intervals is included in either G_u or H_u. Now

$$A = \{u : \text{there are successive constituent intervals of } \mathbb{R} \setminus D_u \text{ both included in } G_u\}$$

is negligible. **P?** Otherwise, there are rationals $q < q'$ such that

$$F = \{u :]q, q'[\setminus G_u \text{ contains exactly one point}\}$$

is not negligible. Note that, writing $T : \mathbb{R}^r \to \mathbb{R}^{r-1}$ for the orthogonal projection,

$$F = T[(\mathbb{R}^{r-1} \times]q, q'[) \setminus \text{int}^* E] \setminus \bigcup_{q'' \in \mathbb{Q}, q < q'' < q'} T[(\mathbb{R}^{r-1} \times]q, q''[) \setminus \text{int}^* E] \cap T[(\mathbb{R}^{r-1} \times]q'', q'[) \setminus \text{int}^* E]$$

is measurable. Take any $u \in F \cap \text{int}^* F$, and let t be the unique point in $]q, q'[\setminus G_u$. Then whenever $0 < \delta \leq \min(t - q, q' - t)$ we shall have

$$\mu(B((u, t), \delta) \setminus E) = \mu(B((u, t), \delta) \setminus \text{int}^* E) \leq 2\delta \mu_{r-1}(V(u, \delta) \setminus F),$$

because if $w \in F$ then $(w, s) \in \text{int}^* E$ for almost every $s \in [t - \delta, t + \delta]$. So

$$\limsup_{\delta \downarrow 0} \frac{\mu(B((u,t),\delta) \setminus E)}{\mu B((u,t),\delta)} \leq \frac{2\beta_{r-1}}{\beta_r} \limsup_{\delta \downarrow 0} \frac{\mu_{r-1}(V(u,\delta) \setminus F)}{\mu_{r-1} V(u,\delta)} = 0,$$

and $(u, t) \in \text{int}^* E$. **XQ**

Similarly,

$$A' = \{u : \text{there are successive constituent intervals of } \mathbb{R} \setminus D_u \text{ both included in } H_u\}$$

is negligible. So $Z_2 \setminus (A \cup A')$ is a conegligible set of the kind we need.

475K Lemma Suppose that $h : \mathbb{R}^r \to [-1,1]$ is a Lipschitz function with compact support; let $n \in \mathbb{N}$ be such that $h(x) = 0$ for $\|x\| \geq n$. Suppose that $E \subseteq \mathbb{R}^r$ is a Lebesgue measurable set. Then

$$|\int_E \frac{\partial h}{\partial \xi_r} d\mu| \leq 2\big(\beta_{r-1} n^{r-1} + \nu(\partial^* E \cap B(\mathbf{0}, n))\big).$$

proof (a) Since (as noted in 473Cc) $\frac{\partial h}{\partial \xi_r}$ is defined almost everywhere, is measurable and bounded, and is zero outside $B(\mathbf{0}, n)$, the integral is well-defined. If $\nu(\partial^* E \cap B(\mathbf{0}, n))$ is infinite, the result is trivial; so henceforth let us suppose that $\nu(\partial^* E \cap B(\mathbf{0}, n)) < \infty$. Identify $\mathbb{R}^r$ with $\mathbb{R}^{r-1} \times \mathbb{R}$. For $u \in \mathbb{R}^{r-1}$, set

$$\begin{aligned} f(u) &= \#(\{t : (u,t) \in \partial^* E \cap B(\mathbf{0}, n)\}) \text{ if this is finite,} \\ &= \infty \text{ otherwise.} \end{aligned}$$

By 475H, $\int f d\mu_{r-1} \leq \nu(\partial^* E \cap B(\mathbf{0}, n))$. By 475J, there is a μ_{r-1}-conegligible set $Z \subseteq \mathbb{R}^{r-1}$ such that

whenever $u \in Z$ and $(u,t) \in \operatorname{int}^* E$ and $(u,t') \in \mathbb{R}^r \setminus \operatorname{cl}^* E$, there is an s lying between t and t' such that $(u,s) \in \partial^* E$;

we may suppose also that $f(u)$ is finite for every $u \in Z$. For $u \in Z$, set $D'_u = \{t : (u,t) \in B(\mathbf{0}, n) \setminus \partial^* E\}$, and define $g_u : D'_u \to \{0,1\}$ by setting

$$\begin{aligned} g_u(t) &= 1 \text{ if } u \in Z \text{ and } (u,t) \in B(\mathbf{0}, n) \cap \operatorname{int}^* E, \\ &= 0 \text{ if } u \in Z \text{ and } (u,t) \in B(\mathbf{0}, n) \setminus \operatorname{cl}^* E. \end{aligned}$$

Now if $t, t' \in D'_u$ and $g(t) \neq g(t')$, there is a point s between t and t' such that $(u,s) \in \partial^* E$; so the variation $\operatorname{Var}_{D_u} g_u$ of g_u (224A) is at most $f(u)$. Setting $h_u(t) = h(u,t)$ for $u \in \mathbb{R}^{r-1}$ and $t \in \mathbb{R}$, we now have

$$\int_{-\infty}^{\infty} \frac{\partial h}{\partial \xi_r}(u,t) \chi(B(\mathbf{0}, n) \cap \operatorname{int}^* E)(u,t) dt = \int_{D_u} h'_u(t) g_u(t) dt$$

(because $h'_u(t) = 0$ if $(u,t) \notin B(\mathbf{0}, n)$)

$$\leq \big(1 + \operatorname*{Var}_{D'_u} g_u\big) \sup_{a \leq b} |\int_a^b h'_u(t)| dt$$

(by 224J, recalling that D'_u is either empty or a bounded interval with finitely many points deleted)

$$\leq (1 + f(u)) \sup_{a \leq b} |h_u(b) - h_u(a)|$$

(because h_u is Lipschitz, therefore absolutely continuous on any bounded interval)

$$\leq 2(1 + f(u)).$$

Integrating over u, we now have

$$|\int_E \frac{\partial h}{\partial \xi_r} d\mu| = |\int_{B(\mathbf{0}, n) \cap \operatorname{int}^* E} \frac{\partial h}{\partial \xi_r} d\mu|$$

(475Cg)

$$= \int_{V(\mathbf{0}, n)} \int_{-\infty}^{\infty} \frac{\partial h}{\partial \xi_r}(u,t) \chi(B(\mathbf{0}, n) \cap \operatorname{int}^* E)(u,t) dt \, \mu_{r-1}(du)$$

(where $V(\mathbf{0}, n) = \{u : u \in \mathbb{R}^{r-1}, \|u\| \leq n\}$)

$$\leq \int_{V(\mathbf{0}, n)} 2(1 + f(u)) \mu_{r-1}(du)$$

$$\leq 2\big(\beta_{r-1} n^{r-1} + \nu(\partial^* E \cap B(\mathbf{0}, n))\big).$$

475L Theorem Suppose that $E \subseteq \mathbb{R}^r$. Then E has locally finite perimeter iff $\nu(\partial^*E \cap B(\mathbf{0},n))$ is finite for every $n \in \mathbb{N}$.

proof If E has locally finite perimeter, then $\nu(\partial^*E \cap B(\mathbf{0},n)) = \lambda_E^\partial B(\mathbf{0},n)$ is finite for every n, by 475G. So let us suppose that $\nu(\partial^*E \cap B(\mathbf{0},n))$ is finite for every $n \in \mathbb{N}$.

If $n \in \mathbb{N}$, then

$$\sup\{|\int_E \operatorname{div}\phi\, d\mu| : \phi : \mathbb{R}^r \to \mathbb{R}^r \text{ is Lipschitz, } \|\phi\| \leq \chi B(\mathbf{0},n)\} \leq 2r\big((\beta_{r-1}n^{r-1} + \nu(\partial^*E \cap B(\mathbf{0},n))\big)$$

is finite. **P** If $\phi = (\phi_1,\dots,\phi_r) : \mathbb{R}^r \to \mathbb{R}^r$ is a Lipschitz function and $\|\phi\| \leq \chi B(\mathbf{0},n)$, then 475K tells us that

$$|\int_E \frac{\partial\phi_r}{\partial\xi_r} d\mu| \leq 2\big(\beta_{r-1}n^{r-1} + \nu(\partial^*E \cap B(\mathbf{0},n))\big).$$

But of course it is equally true that

$$|\int_E \frac{\partial\phi_j}{\partial\xi_j} d\mu| \leq 2\big(\beta_{r-1}n^{r-1} + \nu(\partial^*E \cap B(\mathbf{0},n))\big)$$

for every $j \leq r$; adding, we have the result. **Q**

Since n is arbitrary, E has locally finite perimeter.

475M Corollary (a) The family of sets with locally finite perimeter is a subalgebra of the algebra of Lebesgue measurable subsets of $\mathbb{R}^r$.

(b) A set $E \subseteq \mathbb{R}^r$ has finite perimeter iff $\nu(\partial^*E) < \infty$, and in this case $\nu(\partial^*E)$ is the perimeter of E.

(c) If $E \subseteq \mathbb{R}^r$ has finite measure, then $\operatorname{per} E = \liminf_{\alpha\to\infty} \operatorname{per}(E \cap B(\mathbf{0},\alpha))$.

proof (a) Recall that the definition in 474D insists that sets with locally finite perimeter should be Lebesgue measurable. If $E \subseteq \mathbb{R}^r$ has locally finite perimeter, then so does $\mathbb{R}^r \setminus E$, by 474J. If E, $F \subseteq \mathbb{R}^r$ have locally finite perimeter, then

$$\nu(\partial^*(E \cup F) \cap B(\mathbf{0},n)) \leq \nu(\partial^*E \cap B(\mathbf{0},n)) + \nu(\partial^*F \cap B(\mathbf{0},n))$$

is finite for every $n \in \mathbb{N}$, by 475L and 475Cd; by 475L in the other direction, $E \cup F$ has locally finite perimeter.

(b) If E has finite perimeter (on the definition in 474D), then it is measurable and $\nu(\partial^*E) = \lambda_E^\partial\mathbb{R}^r$ is the perimeter of E, by 475G. If $\nu(\partial^*E) < \infty$, then $\mu(\partial^*E) = 0$ (471L) so E is measurable (475Ch); now E has locally finite perimeter, by 475L, and 475G again tells us that $\nu(\partial^*E) = \lambda_E^\partial\mathbb{R}^r$ is the perimeter of E.

(c) Now suppose that μE is finite. For any $\alpha \geq 0$,

$$\partial^*(E \cap B(\mathbf{0},\alpha)) \subseteq (\partial^*E \cap B(\mathbf{0},\alpha)) \cup \partial B(\mathbf{0},\alpha)$$

by 475Cf; since certainly

$$\partial^*(E \cap B(\mathbf{0},\alpha)) \subseteq \operatorname{cl}^*(E \cap B(\mathbf{0},\alpha)) \subseteq \operatorname{cl}^*E,$$

$$\partial^*(E \cap B(\mathbf{0},\alpha)) \subseteq \partial^*E \cup (\operatorname{cl}^*E \cap \partial B(\mathbf{0},\alpha)).$$

Now we know also that

$$\int_0^\infty \nu(\operatorname{cl}^*E \cap \partial B(\mathbf{0},\alpha))d\alpha = \mu E < \infty$$

(265G), so $\liminf_{\alpha\to\infty} \nu(\operatorname{cl}^*E \cap \partial B(\mathbf{0},\alpha)) = 0$. This means that

$$\liminf_{\alpha\to\infty} \operatorname{per}(E \cap B(\mathbf{0},\alpha)) = \liminf_{\alpha\to\infty} \nu(\partial^*(E \cap B(\mathbf{0},\alpha))) \leq \liminf_{\alpha\to\infty} \nu(\partial^*E) + \nu(\operatorname{cl}^*E \cap \partial B(\mathbf{0},\alpha)) = \nu(\partial^*E).$$

In the other direction,

$$\partial^*E \cap U(\mathbf{0},\alpha) = \partial^*E \cap \operatorname{int}^*B(\mathbf{0},\alpha) \subseteq \partial^*(E \cap B(\mathbf{0},\alpha))$$

for every α, by 475Cb, so

$$\begin{aligned}\operatorname{per} E = \nu(\partial^* E) &= \lim_{\alpha\to\infty} \nu(\partial^* E \cap U(\mathbf{0},\alpha)) \\ &\leq \liminf_{\alpha\to\infty} \nu(\partial^*(E\cap B(\mathbf{0},\alpha))) = \liminf_{\alpha\to\infty} \operatorname{per}(E\cap B(\mathbf{0},\alpha))\end{aligned}$$

and we must have equality.

Remark See 475Xj, 475Xk.

475N The Divergence Theorem Let $E \subseteq \mathbb{R}^r$ be such that $\nu(\partial^* E \cap B(\mathbf{0},n))$ is finite for every $n \in \mathbb{N}$.
(a) For ν-almost every $x \in \partial^* E$, there is a Federer exterior normal v_x of E at x.
(b) For every Lipschitz function $\phi : \mathbb{R}^r \to \mathbb{R}^r$ with compact support,

$$\int_E \operatorname{div}\phi \, d\mu = \int_{\partial^* E} \phi(x) \boldsymbol{.} v_x \, \nu(dx).$$

proof By 475L, E has locally finite perimeter. By 474Q, there is a Federer exterior normal $v_x = \psi_E(x)$ of E at x for every $x \in \partial^{\$} E$; by 475D, ν-almost every point in $\partial^* E$ is of this kind. By 474E-474F,

$$\int_E \operatorname{div}\phi \, d\mu = \int \phi \boldsymbol{.} \psi_E \, d\lambda_E^{\partial} = \int_{\partial^{\$} E} \phi \boldsymbol{.} \psi_E \, d\lambda_E^{\partial},$$

and this is also equal to $\int_{\partial^* E} \phi \boldsymbol{.} \psi_E \, d\lambda_E^{\partial}$, because $\partial^{\$} E \subseteq \partial^* E$. But λ_E^{∂} and ν induce the same subspace measures on $\partial^* E$, by 475G, so

$$\int_E \operatorname{div}\phi \, d\mu = \int_{\partial^* E} \phi \boldsymbol{.} \psi_E \, d\nu = \int_{\partial^* E} \phi(x) \boldsymbol{.} v_x \, \nu(dx),$$

as claimed.

475O Lemma Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter, and ψ_E its canonical outward normal. Let v be the unit vector $(0,\dots,0,1)$. Identify $\mathbb{R}^r$ with $\mathbb{R}^{r-1}\times\mathbb{R}$. Then we have sequences $\langle F_n\rangle_{n\in\mathbb{N}}$, $\langle g_n\rangle_{n\in\mathbb{N}}$ and $\langle g_n'\rangle_{n\in\mathbb{N}}$ such that
(i) for each $n \in \mathbb{N}$, F_n is a Lebesgue measurable subset of $\mathbb{R}^{r-1}$, and g_n, $g_n' : F_n \to [-\infty,\infty]$ are Lebesgue measurable functions such that $g_n(u) < g_n'(u)$ for every $u \in F_n$;
(ii) if m, $n \in \mathbb{N}$ then $g_m(u) \neq g_n'(u)$ for every $u \in F_m \cap F_n$;
(iii) $\sum_{n=0}^{\infty} \int_{F_n} g_n' - g_n d\mu_{r-1} = \mu E$;
(iv) for any continuous function $h : \mathbb{R}^r \to \mathbb{R}$ with compact support,

$$\int_{\partial^* E} h(x) v \boldsymbol{.} \psi_E(x) \, \nu(dx) = \sum_{n=0}^{\infty} \int_{F_n} h(u, g_n'(u)) - h(u, g_n(u)) \mu_{r-1}(du),$$

where we interpret $h(u,\infty)$ and $h(u,-\infty)$ as 0 if necessary;
(v) for μ_{r-1}-almost every $u \in \mathbb{R}^{r-1}$,

$$\begin{aligned}\{t : (u,t) \in \partial^* E\} = \{g_n(u) : n \in \mathbb{N},\, u \in F_n,\, g_n(u) \neq -\infty\} \\ \cup \{g_n'(u) : n \in \mathbb{N},\, u \in F_n,\, g_n'(u) \neq \infty\}.\end{aligned}$$

proof (a) Take a conegligible set $Z \subseteq \mathbb{R}^{r-1}$ as in 475Jb. It will be convenient to shrink Z down further, if necessary, to a conegligible Borel set. For $u \in Z$ set $D_u = \{t : (u,t) \in \partial^* E\}$.

(b) For each $q \in \mathbb{Q}$, set $F_q' = \{u : u \in Z,\, (u,q) \in \operatorname{int}^* E\}$, so that F_q' is a Borel set, and for $u \in F_q'$ set

$$f_q(u) = \sup(D_u \cap]-\infty, q[), \quad f_q'(u) = \inf(D_u \cap]-\infty, q[),$$

allowing $-\infty$ as $\sup\emptyset$ and ∞ as $\inf\emptyset$. Observe that (because $D_u \cap [q-1, q+1]$ is finite) $f_q(u) < q < f_q'(u)$. Now f_q and f_q' are measurable, by the argument of part (a-i) of the proof of 475J. Enumerate $\mathbb{Q}$ as $\langle q_n\rangle_{n\in\mathbb{N}}$, and set

$$F_n = F_{q_n} \setminus \bigcup_{m<n} \{u : u \in F_{q_m},\, f_{q_m}(u) < q_n < f_{q_m}'(u)\}$$

for $n \in \mathbb{N}$. Set $g_n(u) = f_{q_n}(u)$, $g_n'(u) = f_{q_n}'(u)$ for $u \in F_n$.

The effect of this construction is to ensure that, for any $u \in Z$, $u \in F_{q_n}$ iff q_n is the first rational lying in one of those constituent intervals I of $\mathbb{R} \setminus D_u$ such that $\{u\} \times I \subseteq \operatorname{int}^* E$, and that now $g_n(u)$ and $g_n'(u)$ are the endpoints of that interval, allowing $\pm\infty$ as endpoints.

(c) Now let us look at the items (i)-(v) of the statement of this lemma. We have already achieved (i). If $u \in F_m \cap F_n$, then $g_m(u)$ is the infimum of one of the constituent intervals of G_u, and $g'_n(u)$ is either ∞ or the infimum of one of the constituent intervals of H_u; so $g_m(u) \neq g'_n(u)$. Thus (ii) is true. For any $u \in Z$,

$$\sum_{n\in\mathbb{N},u\in F_n} g'_n(u) - g_n(u) = \mu_1\{t : (u,t) \in \text{int}^*E\},$$

so

$$\sum_{n=0}^{\infty}\int_{F_n} g'_n - g_n d\mu_{r-1} = \int_Z \mu_1\{t : (u,t) \in \text{int}^*E\}\mu_{r-1}(du) = \mu(\text{int}^*E) = \mu E.$$

So (iii) is true. Also, for $u \in Z$,

$$\begin{aligned}\{t : (u,t) \in \partial^*E\} &= D_u \\ &= \{g_n(u) : n \in \mathbb{N},\, u \in F_n,\, g_n(u) \neq -\infty\} \\ &\qquad \cup \{g'_n(u) : n \in \mathbb{N},\, u \in F_n,\, g'_n(u) \neq \infty\},\end{aligned}$$

so (v) is true.

(d) As for (iv), suppose first that $h : \mathbb{R}^r \to \mathbb{R}$ is a Lipschitz function with compact support. Set $\phi(x) = (0, \dots, h(x))$ for $x \in \mathbb{R}^r$. Then

$$\begin{aligned}\int_{\partial^*E} h(x)v.\psi_E(x)\,\nu(dx) &= \int h(x)v.\psi_E(x)\,\lambda_E^{\partial}(dx) \\ &\text{(475G)} \\ &= \int \phi.\psi_E\,\lambda_E^{\partial}(dx) = \int_E \operatorname{div}\phi\,d\mu \\ &\text{(474E)} \\ &= \int_E \frac{\partial h}{\partial\xi_r}\,d\mu = \int_{\text{int}^*E} \frac{\partial h}{\partial\xi_r}\,d\mu \\ &= \int \sum_{n\in\mathbb{N},u\in F_n} \int_{g_n(u)}^{g'_n(u)} \frac{\partial h}{\partial\xi_r}(u,t)dt\,\mu_{r-1}(du) \\ &= \int \sum_{n\in\mathbb{N},u\in F_n} h(u,g'_n(u)) - h(u,g_n(u))\mu_{r-1}(du) \\ &\text{(with the convention that } h(u,\pm\infty) = \lim_{t\to\pm\infty} h(u,t) = 0) \\ &= \sum_{n=0}^{\infty}\int_{F_n} h(u,g'_n(u)) - h(u,g_n(u))\mu_{r-1}(du)\end{aligned}$$

because if $|h| \leq m\chi B(\mathbf{0},m)$ then

$$\begin{aligned}\int \sum_{n\in\mathbb{N},u\in F_n} &|h(u,g'_n(u)) - h(u,g_n(u))|\mu_{r-1}(du) \\ &\leq 2m\int \#(\{t : (u,t) \in B(\mathbf{0},m) \cap \partial^*E\})\mu_{r-1}(du) \\ &\leq 2m\nu(B(\mathbf{0},m) \cap \partial^*E)\end{aligned}$$

(475H) is finite.

For a general continuous function h of compact support, consider the convolutions $h_k = h * \tilde{h}_k$ for large k, where $\tilde{h}_k$ is defined in 473E. If $|h| \leq m\chi B(\mathbf{0},m)$ then $|h_k| \leq m\chi B(\mathbf{0},m+1)$ for every k, so that

$$\sum_{n\in\mathbb{N},u\in F_n} |h_k(g'_n(u)) - h_k(g_n(u))| \leq 2m\#(\{t : (u,t) \in B(\mathbf{0},m+1) \cap \partial^*E\})$$

for every $u \in \mathbb{R}^r$, $k \in \mathbb{N}$. Since $h_k \to h$ uniformly (473Ed),

$$\begin{aligned}\int_{\partial^*E} h(x)v\boldsymbol{.}\psi_E(x)\,\nu(dx) &= \lim_{k\to\infty}\int_{\partial^*E} h_k(x)v\boldsymbol{.}\psi_E(x)\,\nu(dx)\\ &= \lim_{k\to\infty}\int \sum_{n\in\mathbb{N},u\in F_n} h_k(u,g_n'(u)) - h_k(u,g_n(u))\mu_{r-1}(du)\\ &= \int \sum_{n\in\mathbb{N},u\in F_n} h(u,g_n'(u)) - h(u,g_n(u))\mu_{r-1}(du)\\ &= \sum_{n=0}^{\infty}\int_{F_n} h(u,g_n'(u)) - h(u,g_n(u))\mu_{r-1}(du),\end{aligned}$$

as required.

475P Lemma Let $v \in S_{r-1}$ be any unit vector, and $V \subseteq \mathbb{R}^r$ the hyperplane $\{x : x\boldsymbol{.}v = 0\}$. Let $T : \mathbb{R}^r \to V$ be the orthogonal projection. If $E \subseteq \mathbb{R}^r$ is any set with locally finite perimeter and canonical outward normal ψ_E, then

$$\int_{\partial^*E} |v\boldsymbol{.}\psi_E|d\nu = \int_V \#(\partial^*E \cap T^{-1}[\{u\}])\nu(du).$$

proof As usual, we may suppose that the structure (E, v) is rotated until $v = (0, \dots, 1)$, so that we can identify $T(\xi_1, \dots, \xi_r)$ with $(\xi_1, \dots, \xi_{r-1}) \in \mathbb{R}^{r-1}$, and $\int_V \#(\partial^*E \cap T^{-1}[\{u\}])\nu(du)$ with $\int_{\mathbb{R}^{r-1}} \#(D_u)\mu_{r-1}(du)$, where $D_u = \{t : (u,t) \in \partial^*E\}$.

(a) Write Φ for the set of continuous functions $h : \mathbb{R}^r \to [-1,1]$ with compact support. Then

$$\int_{\partial^*E} |v\boldsymbol{.}\psi_E|d\nu = \sup_{h\in\Phi}\int_{\partial^*E} h(x)v\boldsymbol{.}\psi_E(x)\,\nu(dx).$$

P Of course

$$\int_{\partial^*E} |v\boldsymbol{.}\psi_E|d\nu \geq \int_{\partial^*E} h(x)v\boldsymbol{.}\psi_E(x)\,\nu(dx)$$

for any $h \in \Phi$. On the other hand, if

$$\gamma < \int_{\partial^*E} |v\boldsymbol{.}\psi_E|d\nu = \int |v\boldsymbol{.}\psi_E|d\lambda_E^{\partial}$$

(475G), then, because λ_E^{∂} is a Radon measure, there is an $n \in \mathbb{N}$ such that

$$\gamma < \int_{B(\mathbf{0},n)} |v\boldsymbol{.}\psi_E|d\lambda_E^{\partial} = \int h_0(x)v\boldsymbol{.}\psi_E(x)\,\lambda_E^{\partial}(dx)$$

where

$$\begin{aligned}h_0(x) &= \frac{v\boldsymbol{.}\psi_E(x)}{|v\boldsymbol{.}\psi_E(x)|} \text{ if } x \in B(\mathbf{0},n) \text{ and } v\boldsymbol{.}\psi_E(x) \neq 0\\ &= 0 \text{ otherwise.}\end{aligned}$$

Because λ_E^{∂} is a Radon measure, there is a continuous function $h_1 : \mathbb{R}^r \to \mathbb{R}$ with compact support such that

$$\int |h_1 - h_0|d\lambda_E^{\partial} \leq \int_{B(\mathbf{0},n)} |v\boldsymbol{.}\psi_E|d\lambda_E^{\partial} - \gamma$$

(416I); of course we may suppose that h_1, like h, takes values in $[-1,1]$, so that $h_1 \in \Phi$. Now

$$\int_{\partial^*E} h_1(x)v\boldsymbol{.}\psi_E(x)\nu(dx) = \int h_1(x)v\boldsymbol{.}\psi_E(x)\,\lambda_E^{\partial}(dx) \geq \gamma.$$

As γ is arbitrary,

$$\sup_{h\in\Phi}\int h(x)v\boldsymbol{.}\psi_E(x)\,\nu(dx) = \int |v\boldsymbol{.}\psi_E|d\nu$$

as required. **Q**

(b) Now take $\langle F_n\rangle_{n\in\mathbb{N}}$, $\langle g_n\rangle_{n\in\mathbb{N}}$ and $\langle g_n'\rangle_{n\in\mathbb{N}}$ as in 475O. Then

$$\int \#(D_u)\mu_{r-1}(du) = \sup_{h\in\Phi}\textstyle\sum_{n=0}^{\infty}\int_{F_n} h(u,g_n'(u)) - h(u,g_n(u))\mu_{r-1}(du).$$

P By 475O(ii), $g'_m(u) \neq g_n(u)$ whenever $m, n \in \mathbb{N}$ and $u \in F_m \cap F_n$, while for almost all $u \in \mathbb{R}^{r-1}$

$$D_u = (\{g_n(u) : n \in \mathbb{N},\, u \in F_n\} \setminus \{-\infty\}) \cup (\{g'_n(u) : n \in \mathbb{N},\, u \in F_n\} \setminus \{\infty\}).$$

So if $h \in \Phi$,

$$\begin{aligned}\sum_{n\in\mathbb{N},u\in F_n} h(u,g'_n(u)) - h(u,g_n(u)) &\leq \#(\{g_n(u) : u \in F_n,\, g_n(u) \neq -\infty\}) \\ &\quad + \#(\{g'_n(u) : u \in F_n,\, g'_n(u) \neq \infty\}) \\ &= \#(D_u)\end{aligned}$$

for almost every $u \in \mathbb{R}^{r-1}$, and

$$\textstyle\sum_{n=0}^{\infty} \int_{F_n} h(u,g'_n(u)) - h(u,g_n(u))\mu_{r-1}(du) \leq \int \#(D_u)\mu_{r-1}(du).$$

In the other direction, given $\gamma < \int \#(D_u)\mu_{r-1}(du)$, there is an $m \in \mathbb{N}$ such that $\gamma < \int \#(D_u^{(m)})\mu_{r-1}(du)$, where $D_u^{(m)} = \{t : (u,t) \in \partial^* E,\, \|(u,t)\| < m\}$. Note that $\int \#(D_u^{(m)})\mu_{r-1}(du) \leq \nu(\partial^* E \cap B(\mathbf{0},m))$ is finite. Setting

$$H_n = \{u : u \in F_n,\, g_n(u) \in D_u^{(m)}\}, \quad H'_n = \{u : u \in F_n,\, g'_n(u) \in D_u^{(m)}\}$$

for $n \in \mathbb{N}$, we have

$$\gamma < \textstyle\sum_{n=0}^{\infty} \mu_{r-1}H_n + \sum_{n=0}^{\infty} \mu_{r-1}H'_n < \infty.$$

By Lusin's theorem (418J), we can find $n \in \mathbb{N}$ and compact sets $K_i \subseteq H_i$, $K'_i \subseteq H'_i$ such that $g_i{\restriction}K_i$ and $g'_i{\restriction}K'_i$ are continuous for every i and

$$\begin{aligned}\gamma &\leq \sum_{i=0}^{n} (\mu_{r-1}K_i + \mu_{r-1}K'_i) - \sum_{i=n+1}^{\infty} (\mu_{r-1}H_i + \mu_{r-1}H'_i) \\ &\quad - \sum_{i=0}^{n} (\mu_{r-1}(H_i \setminus K_i) + \mu_{r-1}(H'_i \setminus K'_i)).\end{aligned}$$

Set

$$K = \textstyle\bigcup_{i\leq n} \{(u, g_i(u)) : u \in K_i\}, \quad K' = \bigcup_{i\leq n} \{(u, g'_i(u)) : u \in K'_i\},$$

so that K and K' are disjoint compact subsets of $\operatorname{int} B(\mathbf{0},m)$. Let $h : \mathbb{R}^r \to \mathbb{R}$ be a continuous function such that

$$\begin{aligned}h(x) &= 1 \text{ for } x \in K', \\ &= -1 \text{ for } x \in K, \\ &= 0 \text{ for } x \in \mathbb{R}^r \setminus \operatorname{int} B(\mathbf{0},m)\end{aligned}$$

(4A2F(d-viii)); we can suppose that $-1 \leq h(x) \leq 1$ for every x. Then $h \in \Phi$, and

$$\begin{aligned}&\sum_{i=0}^{\infty} \int_{F_i} h(u,g'_i(u)) - h(u,g_i(u))\mu_{r-1}(du) \\ &\qquad = \sum_{i=0}^{\infty} \int_{H'_i} h(u,g'_i(u))\mu_{r-1}(du) - \sum_{i=0}^{\infty} \int_{H_i} h(u,g_i(u))\mu_{r-1}(du) \\ &\text{(because } h \text{ is zero outside } \operatorname{int} B(\mathbf{0},m)) \\ &\qquad \geq \sum_{i=0}^{n} \int_{K'_i} h(u,g'_i(u))\mu_{r-1}(du) - \sum_{i=0}^{n} \int_{K_i} h(u,g_i(u))\mu_{r-1}(du) \\ &\qquad\quad - \sum_{i=0}^{n} (\mu(H'_i \setminus K'_i) + \mu(H_i \setminus K_i)) - \sum_{i=n+1}^{\infty} (\mu H'_i + \mu H_i) \\ &\qquad \geq \gamma.\end{aligned}$$

This shows that

$$\int \#(D_u)\mu_{r-1}(du) \leq \sup_{h\in\Phi}\sum_{n=0}^{\infty}\int_{F_n} h(u,g_n'(u)) - h(u,g_n(u))\mu_{r-1}(du),$$

and we have equality. **Q**

(c) Putting (a) and (b) together with 475O(iv), we have the result.

475Q Theorem Let $E \subseteq \mathbb{R}^r$ be a set with finite perimeter. For $v \in S^{r-1}$ write V_v for $\{x : x.v = 0\}$, and let $T_v : \mathbb{R}^r \to V_v$ be the orthogonal projection. Then

$$\nu(\partial^*E) = \frac{1}{2\beta_{r-1}}\int_{S_{r-1}}\int_{V_v} \#(\partial^*E \cap T_v^{-1}[\{u\}])\nu(du)\nu(dv).$$

proof (a) I start with an elementary fact: there is a constant c such that $\int |w.v|\lambda^{\partial}_{S_{r-1}}(dv) = c$ for every $w \in S_{r-1}$; this is because whenever w, $w' \in S_{r-1}$ there is an orthogonal linear transformation taking w to w', and this transformation is an automorphism of the structure $(\mathbb{R}^r, \nu, S_{r-1}, \lambda^{\partial}_{S_{r-1}})$ (474H). (Later in the proof I will come to the calculation of c.)

(b) Now, writing ψ_E for the canonical outward normal of E, we have

$$\int_{S_{r-1}}\int_{V_v} \#(\partial^*E \cap T_v^{-1}[\{u\}])\nu(du)\nu(dv) = \int_{S_{r-1}}\int_{\partial^*E} |\psi_E(x).v|\nu(dx)\nu(dv)$$

(475P)

$$= \iint |\psi_E(x).v|\lambda^{\partial}_E(dx)\lambda^{\partial}_{S_{r-1}}(dv)$$

(by 235M, recalling that $\lambda^{\partial}_{S_{r-1}}$ and λ^{∂}_E are just indefinite-integral measures over ν, while S_{r-1} and ∂^*E are Borel sets)

$$= \iint |\psi_E(x).v|\lambda^{\partial}_{S_{r-1}}(dv)\lambda^{\partial}_E(dx)$$

(because $.$ is continuous, so $(x,v) \mapsto \psi_E(x).v$ is measurable, while $\lambda^{\partial}_{S_{r-1}}$ and λ^{∂}_E are totally finite, so we can use Fubini's theorem)

$$= c\operatorname{per} E$$

(by (a) above)

$$= c\nu(\partial^*E).$$

(c) We have still to identify the constant c. But observe that the argument above applies whenever $\nu(\partial^*E)$ is finite, and in particular applies to $E = B(\mathbf{0},1)$. In this case, $\partial^*B(\mathbf{0},1) = S_{r-1}$, and for any $v \in S_{r-1}$, $u \in V_v$ we have

$$\begin{aligned}\#(\partial^*B(\mathbf{0},1) \cap T^{-1}[\{u\}]) &= 2 \text{ if } \|u\| < 1,\\ &= 1 \text{ if } \|u\| = 1,\\ &= 0 \text{ if } \|u\| > 1.\end{aligned}$$

Since we can identify ν on V_v as a copy of Lebesgue measure μ_{r-1},

$$\int_{V_v} \#(\partial^*B(\mathbf{0},1) \cap T^{-1}[\{u\}])\nu(du) = 2\nu\{u : u \in V_v, \|u\| < 1\} = 2\beta_{r-1}.$$

This is true for every $v \in V_u$, so from (b) we get

$$2\beta_{r-1}\nu S_{r-1} = \int_{S_{r-1}}\int_{V_v} \#(\partial^*E \cap T_v^{-1}[\{u\}])\nu(du)\nu(dv) = c\nu S_{r-1},$$

and $c = 2\beta_{r-1}$. Substituting this into (b), we have the result.

475R Convex sets in $\mathbb{R}^r$ For the next theorem it will help to have some elementary facts about convex sets in finite-dimensional spaces out in the open.

Lemma (In this lemma I allow $r = 1$.) Let $C \subseteq \mathbb{R}^r$ be a convex set.
(a) If $x \in C$ and $y \in \operatorname{int} C$, then $ty + (1-t)x \in \operatorname{int} C$ for every $t \in]0,1]$.
(b) $\overline{C}$ and $\operatorname{int} C$ are convex.
(c) If $\operatorname{int} C \neq \emptyset$ then $\overline{C} = \overline{\operatorname{int} C}$.
(d) If $\operatorname{int} C = \emptyset$ then C lies within some hyperplane.
(e) $\operatorname{int} \overline{C} = \operatorname{int} C$.

proof (a) Setting $\phi(z) = x + t(z-x)$ for $z \in \mathbb{R}^r$, $\phi : \mathbb{R}^r \to \mathbb{R}^r$ is a homeomorphism and $\phi[C] \subseteq C$, so

$$\phi(y) \in \phi[\operatorname{int} C] = \operatorname{int} \phi[C] \subseteq \operatorname{int} C.$$

(b) It follows at once from (a) that $\operatorname{int} C$ is convex; $\overline{C}$ is convex because $(x,y) \mapsto tx + (1-t)y$ is continuous for every $t \in [0,1]$.

(c) From (a) we see also that if $\operatorname{int} C \neq \emptyset$ then $C \subseteq \overline{\operatorname{int} C}$, so that $\overline{C} \subseteq \overline{\operatorname{int} C}$ and $\overline{C} = \overline{\operatorname{int} C}$.

(d) It is enough to consider the case in which $\mathbf{0} \in C$, since if $C = \emptyset$ the result is trivial. **?** If $x_1, \dots, x_r$ are linearly independent elements of C, set $x = \frac{1}{r+1}\sum_{i=1}^r x_i$; then

$$x + \textstyle\sum_{i=1}^r \alpha_i x_i = \sum_{i=1}^r (\alpha_i + \frac{1}{r+1}) x_i \in C$$

whenever $\sum_{i=1}^r |\alpha_i| \leq \frac{1}{r+1}$. Also, writing $e_1, \dots, e_r$ for the standard orthonormal basis of $\mathbb{R}^r$, we can express e_i as $\sum_{j=1}^r \alpha_{ij} x_j$ for each j; setting $M = (r+1)\max_{i \leq r} \sum_{j=1}^r |\alpha_{ij}|$, we have $x \pm \frac{1}{M} e_i \in C$ for every $i \leq r$, so that $x + y \in C$ whenever $\|y\| \leq \frac{\sqrt{r}}{M}$, and $x \in \operatorname{int} C$. **X**

So the linear subspace of $\mathbb{R}^r$ spanned by C has dimension at most $r-1$.

(e) If $\operatorname{int} C$ is empty, then (d) shows that C is included in a hyperplane, so that $\operatorname{int} \overline{C}$ is empty. Otherwise, if $x \in \mathbb{R}^r \setminus \operatorname{int} C$, there is an $e \in \mathbb{R}^r$ such that $e \cdot y \leq e \cdot x$ for every $y \in \operatorname{int} C$ (4A4Db, or otherwise). Now, by (c), $e \cdot y \leq e \cdot x$ for every $y \in \overline{C}$, so $x \notin \operatorname{int} \overline{C}$. This shows that $\operatorname{int} \overline{C} \subseteq \operatorname{int} C$, so that the two are equal.
It follows at once that $\partial C = \partial \overline{C}$.

475S Corollary: Cauchy's Perimeter Theorem Let $C \subseteq \mathbb{R}^r$ be a bounded convex set with non-empty interior. For $v \in S^{r-1}$ write V_v for $\{x : x \cdot v = 0\}$, and let $T_v : \mathbb{R}^r \to V_v$ be the orthogonal projection. Then

$$\nu(\partial C) = \frac{1}{\beta_{r-1}} \int_{S_{r-1}} \nu(T_v[C]) \nu(dv).$$

proof (a) The first thing to note is that $\partial^* C = \partial C$. **P** Of course $\partial^* C \subseteq \partial C$ (475Ca). If $x \in \partial C$, there is a half-space V containing x and disjoint from $\operatorname{int} C$ (4A4Db), so that

$$\limsup_{\delta \downarrow 0} \frac{\mu(B(x,\delta) \setminus C)}{\mu B(x,\delta)} \geq \limsup_{\delta \downarrow 0} \frac{\mu(B(x,\delta) \setminus \operatorname{int} V)}{\mu B(x,\delta)} = \frac{1}{2},$$

and $x \notin \operatorname{int}^* C$. On the other hand, if $\eta > 0$ is such that $B(x_0, \eta) \subseteq \operatorname{int} C$, then for any $\delta > 0$ we can set $t = \frac{\delta}{\eta + \|x_0 - x\|}$, and then

$$B(x + t(x_0 - x), t\eta) \subseteq B(x,\delta) \cap \operatorname{int} \overline{C} \subseteq B(x,\delta) \cap C,$$

so that

$$\mu(B(x,\delta) \cap C) \geq \beta_r t^r \eta^r = \big(\frac{\eta}{\|x_0 - x\| + \eta}\big)^r \mu B(x,\delta);$$

as δ is arbitrary, $x \in \operatorname{cl}^* C$. This shows that $\partial C \subseteq \partial^* C$ so that $\partial^* C = \partial C$. **Q**

(b) We have a function $\phi : \mathbb{R}^r \to \overline{C}$ defined by taking $\phi(x)$ to be the unique point of C closest to x, for every $x \in \mathbb{R}^r$ (3A5Ld). This function is 1-Lipschitz. **P** Take any x, $y \in \mathbb{R}^r$ and set $e = \phi(x) - \phi(y)$. We know that $\phi(x) - \epsilon e \in \overline{C}$, so that $\|x - \phi(x) - \epsilon e\| \geq \|x - \phi(x)\|$, for $0 \leq \epsilon \leq 1$; it follows that $(x - \phi(x)) \cdot e \geq 0$. Similarly, $(y - \phi(y)) \cdot (-e) \geq 0$. Accordingly $(x - y) \cdot e \geq e \cdot e$ and $\|x - y\| \geq \|e\|$. As x and y are arbitrary, ϕ is 1-Lipschitz. **Q**

Now suppose that that $C' \supseteq C$ is a closed bounded convex set. Then $\nu(\partial C') \geq \nu(\partial C)$. **P** Let ϕ be the function defined just above. By 264G/471J, $\nu^*(\phi[\partial C']) \leq \nu(\partial C')$. But if $x \in \partial C$, there is an $e \in \mathbb{R}^r \setminus \{0\}$ such that $x \cdot e \geq y \cdot e$ for every $y \in C$. Then $\phi(x + \alpha e) = x$ for every $\alpha \geq 0$. Because C' is closed and bounded, and $x \in C \subseteq C'$, there is a greatest $\alpha \geq 0$ such that $x + \alpha e \in C'$, and in this case $x + \alpha e \in \partial C'$; since $\phi(x + \alpha e) = x$, $x \in \phi[\partial C']$. As x is arbitrary, $\partial C \subseteq \phi[\partial C']$, and

$$\nu(\partial C) \leq \nu^*(\phi[\partial C']) \leq \nu(\partial C'). \quad \textbf{Q}$$

Since we can certainly find a closed convex set $C' \supseteq C$ such that $\nu(\partial C')$ is finite (e.g., any sufficiently large ball or cube), $\nu(\partial C) < \infty$. It follows at once that $\mu(\partial C) = 0$ (471L).

(c) The argument so far applies, of course, to every $r \geq 1$ and every bounded convex set with non-empty interior in $\mathbb{R}^r$. Moving to the intended case $r \geq 2$, and fixing $v \in S_{r-1}$ for the moment, we see that, because T_v is an open map (if we give V_v its subspace topology), $T_v[C]$ is again a bounded convex set with non-empty (relative) interior. Since the subspace measure induced by ν on V is just a copy of Lebesgue measure, (b) tells us that $\nu T_v[C] = \nu(\operatorname{int} T_v[C])$, where here I write $\operatorname{int} T_v[C]$ for the interior of $T_v[C]$ in the subspace topology of V_v. Now the point is that $\operatorname{int} T_v[C] \subseteq T_v[\operatorname{int} C]$. **P** $\operatorname{int} C$ is dense in C (475Rc), so $W = T_v[\operatorname{int} C]$ is an open convex set which is dense in $T_v[C]$; now $W = \operatorname{int} \overline{W}$, taking the interior in V (475Re), so $W \supseteq \operatorname{int} T_v[C]$. **Q**

It follows that $\#(\partial C \cap T_v^{-1}[\{u\}]) = 2$ for every $u \in \operatorname{int} T_v[C]$. **P** $T_v^{-1}[\{u\}]$ is a straight line meeting $\operatorname{int} C$ in y_0 say. Because $\overline{C}$ is a bounded convex set, it meets $T_v^{-1}[\{u\}]$ in a bounded convex set, which must be a non-trivial closed line segment with endpoints y_1, y_2 say. Now certainly neither y_1 nor y_2 can be in the interior of C. Moreover, the open line segments between y_1 and y_0, and between y_2 and y_0, are covered by $\operatorname{int} C$, by 475Ra; so $T_v^{-1}[\{u\}] \cap \partial C = \{y_1, y_2\}$ has just two members. **Q**

(d) This is true for every $v \in S_{r-1}$. But this means that we can apply 475Q to see that

$$\begin{aligned}
\nu(\partial C) = \nu(\partial^* C) &= \frac{1}{2\beta_{r-1}} \int_{S_{r-1}} \int_{V_v} \#(\partial^* E \cap T_v^{-1}[\{u\}]) \nu(du) \nu(dv) \\
&= \frac{1}{2\beta_{r-1}} \int_{S_{r-1}} \int_{T_v[C]} \#(\partial^* E \cap T_v^{-1}[\{u\}]) \nu(du) \nu(dv) \\
&= \frac{1}{2\beta_{r-1}} \int_{S_{r-1}} \int_{\operatorname{int} T_v[C]} \#(\partial^* E \cap T_v^{-1}[\{u\}]) \nu(du) \nu(dv) \\
&= \frac{1}{\beta_{r-1}} \int_{S_{r-1}} \nu(\operatorname{int} T_v[C]) \nu(dv) = \frac{1}{\beta_{r-1}} \int_{S_{r-1}} \nu T_v[C] \nu(dv),
\end{aligned}$$

as required.

475T Corollary: the Convex Isoperimetric Theorem If $C \subseteq \mathbb{R}^r$ is a bounded convex set, then $\nu(\partial C) \leq r\beta_r (\frac{1}{2} \operatorname{diam} C)^{r-1}$.

proof (a) If C is included in some $r-1$-dimensional affine subspace, then

$$\nu(\partial C) = \nu \overline{C} \leq \beta_{r-1} (\tfrac{1}{2} \operatorname{diam} C)^{r-1}$$

by 264H. For completeness, I should check that $\beta_{r-1} \leq r\beta_r$. **P** Comparing 265F with 265H, or working from the formulae in 252Q, we have $r\beta_r = 2\pi\beta_{r-2}$. On the other hand, by the argument of 252Q,

$$\beta_{r-1} = \beta_{r-2} \int_{-\pi/2}^{\pi/2} \cos^{r-1} t \, dt \leq \pi \beta_{r-2},$$

so (not coincidentally) we have a factor of two to spare. **Q**

(b) Otherwise, C has non-empty interior (475Rd), and for any orthogonal projection T of $\mathbb{R}^r$ onto an $r-1$-dimensional linear subspace, $\operatorname{diam} T[C] \leq \operatorname{diam} C$, so $\nu(T[C]) \leq \beta_{r-1}(\frac{1}{2}\operatorname{diam} C)^{r-1}$. Now 475S tells us that

$$\nu(\partial C) \leq (\tfrac{1}{2}\operatorname{diam} C)^{r-1}\nu S_{r-1} = r\beta_r(\tfrac{1}{2}\operatorname{diam} C)^{r-1}.$$

475X Basic exercises (a) Show that if $C \subseteq \mathbb{R}^r$ is convex, then either $\mu C = 0$ and $\partial^* C = \emptyset$, or $\partial^* C = \partial C$.

(b) Let A, $A' \subseteq \mathbb{R}^r$ be any sets. Show that

$$(\partial^* A \cap \operatorname{int}^* A') \cup (\partial^* A' \cap \operatorname{int}^* A) \subseteq \partial^*(A \cap A') \subseteq (\partial^* A \cap \operatorname{cl}^* A') \cup (\partial^* A' \cap \operatorname{cl}^* A).$$

(c) Let $A \subseteq \mathbb{R}^r$ be any set, and B a non-trivial closed ball. Show that

$$\partial^*(A \cap B) \triangle ((B \cap \partial^* A) \cup (A \cap \partial B)) \subseteq ((\operatorname{cl}^* A \setminus A) \cup (A \setminus \operatorname{int}^* A)) \cap \partial B.$$

>(d) Let E, $F \subseteq \mathbb{R}^r$ be measurable sets, and v a Federer exterior normal to E at $x \in \operatorname{int}^* F$. Show that v is a Federer exterior normal to $E \cap F$ at x.

(e) Let $\mathfrak{T}$ be the density topology on $\mathbb{R}^r$ (414P) defined from lower Lebesgue density (341E). Show that, for any $A \subseteq \mathbb{R}^r$, $A \cup \operatorname{cl}^* A$ is the $\mathfrak{T}$-closure of A and $\operatorname{int}^* A$ is the $\mathfrak{T}$-interior of the $\mathfrak{T}$-closure of A.

(f) Let $A \subseteq \mathbb{R}^r$ be any set. Show that $A \setminus \operatorname{cl}^* A$ and $\operatorname{int}^* A \setminus A$ are Lebesgue negligible.

>(g) Let $E \subseteq \mathbb{R}^r$ be such that $\nu(\partial^* E)$ and μE are both finite. Show that, taking v_x to be a Federer exterior normal to E at any point x where this is defined,

$$\int_E \operatorname{div} \phi \, d\mu = \int_{\partial^* E} \phi(x) \boldsymbol{.} v_x \, \nu(dx).$$

for every bounded Lipschitz function $\phi : \mathbb{R}^r \to \mathbb{R}^r$.

>(h) Let $\langle E_n \rangle_{n \in \mathbb{N}}$ be a sequence of measurable subsets of $\mathbb{R}^r$ such that (i) there is a measurable set E such that $\lim_{n\to\infty} \mu((E_n \triangle E) \cap B(\mathbf{0}, m)) = 0$ for every $m \in \mathbb{N}$ (ii) $\sup_{n\in\mathbb{N}} \nu(\partial^* E_n \cap B(\mathbf{0}, m))$ is finite for every $m \in \mathbb{N}$. Show that E has locally finite perimeter. (*Hint*: $\int_E \operatorname{div} \phi \, d\mu = \lim_{n\to\infty} \int_{E_n} \operatorname{div} \phi \, d\mu$ for every Lipschitz function ϕ with compact support.)

(i) Give an example of bounded convex sets E and F such that $\partial^{\$}(E \cup F) \not\subseteq \partial^{\$} E \cup \partial^{\$} F$.

(j) (i) Show that if A, $B \subseteq \mathbb{R}^r$ then $\partial^*(A \cap B) \cap \partial^*(A \cup B) \subseteq \partial^* A \cap \partial^* B$. (ii) Show that if E, $F \subseteq \mathbb{R}$ have finite perimeter then $\operatorname{per}(E \cap F) + \operatorname{per}(E \cup F) \leq \operatorname{per} E + \operatorname{per} F$.

(k) Let $E \subseteq \mathbb{R}^r$ be a set with finite Lebesgue measure and finite perimeter. (i) Show that if $H \subseteq \mathbb{R}^r$ is a half-space, then $\operatorname{per}(E \cap H) \leq \operatorname{per} E$. (*Hint*: 475Ja.) (ii) Show that if $C \subseteq \mathbb{R}^r$ is convex, then $\operatorname{per}(E \cap C) \leq \operatorname{per} E$. (*Hint*: by the Hahn-Banach theorem, C is a limit of polytopes; use 474Sa.) (iii) Show that in 475Mc we have $\operatorname{per} E = \lim_{\alpha\to\infty} \operatorname{per}(E \cap B(\mathbf{0}, \alpha))$.

475Y Further exercises (a) Let B be a non-trivial ball in $\mathbb{R}^r$ with centre y, and v, v' two unit vectors in $\mathbb{R}^r$. Set

$$H = \{x : x \in \mathbb{R}^r, (x-y)\boldsymbol{.}v \leq 0\}, \quad H' = \{x : x \in \mathbb{R}^r, (x-y)\boldsymbol{.}v' \leq 0\}.$$

Show that $\mu((H \triangle H') \cap B) = \frac{1}{\pi} \arccos(v \boldsymbol{.} v') \mu B$.

(b) Show that μ is inner regular with respect to the family of compact sets $K \subseteq \mathbb{R}^r$ such that $\limsup_{\delta\downarrow 0} \frac{\mu(B(x,\delta)\cap K)}{\mu B(x,\delta)} \geq \frac{1}{2}$ for every $x \in K$.

(c) Show that if $E \subseteq \mathbb{R}^r$ has finite perimeter then one of E, $\mathbb{R}^r \setminus E$ has finite measure.

475 Notes and comments The successful identification of the distributionally-defined notion of 'perimeter', as described in §474, with the geometrically accessible concept of Hausdorff measure of an appropriate boundary, is of course the key to any proper understanding of the results of the last section as well as this one. The very word 'perimeter' would be unfair if the perimeter of $E \cup F$ were unrelated to the perimeters of E and F; and from this point of view the reduced boundary is less suitable than the essential boundary (475Cd, 475Xh). If we re-examine 474M, we see that it is saying, in effect, that for many balls B the boundary $\partial^*(E \cap B)$ is nearly $(B \cap \partial^* E) \cup (E \cap \partial B)$, and that an outward-normal function for $E \cap B$ can be assembled from outward-normal functions for E and B. But looking at 475Xc-475Xd we see that this is entirely natural; we need only ensure that $\nu(F \cap \partial B) = 0$ for a μ-negligible set F defined from E; and the 'almost every δ' in the statement of 474M is fully enough to arrange this. On the other hand, 475Xg seems to be very hard to prove without using the identification between $\nu(\partial^* E)$ and $\operatorname{per} E$.

Concerning 475Q, I ought to emphasize that it is *not* generally true that

$$\nu F = \frac{1}{2\beta_{r-1}} \int_{S_{r-1}} \int_{V_v} \#(F \cap T_v^{-1}[\{u\}])\nu(du)\nu(dv)$$

even for $r = 2$ and compact sets F with $\nu F < \infty$. We are here approaching one of the many fundamental concepts of geometric measure theory which I am ignoring. The key word is 'rectifiability'; for 'rectifiable' sets a wide variety of concepts of k-dimensional measure coincide, including the integral-geometric form above, and $\partial^* E$ is rectifiable whenever E has locally finite perimeter (Evans & Gariepy 92, 5.7.3). For the general theory of rectifiable sets, see the last quarter of Mattila 95, or Chapter 3 of Federer 69.

I have already noted that the largest volumes for sets of given diameter or perimeter are provided by balls (see 264H and the notes to §474). The isoperimetric theorem for convex sets (475T) is of the same form: once again, the best constant (here, the largest perimeter for a convex set of given diameter, or the smallest diameter for a convex set of given perimeter) is provided by balls.

476 Concentration of measure

Among the myriad special properties of Lebesgue measure, a particularly interesting one is 'concentration of measure'. For a set of given measure in the plane, it is natural to feel that it is most 'concentrated' if it is a disk. There are many ways of defining 'concentration', and I examine three of them in this section (476J, 476K and 476L); all lead us to Euclidean balls as the 'most concentrated' shapes. On the sphere the same criteria lead us to caps (476O, 476Xj).

All the main theorems of this section will be based on the fact that semi-continuous functions on compact spaces attain their bounds. The compact spaces in question will be spaces of subsets, and I begin with some very general remarks on topologies on such spaces (476A-476F). The facts to be used here will mostly relate to topologies induced by Hausdorff metrics (476A), but I include a mention of Vietoris topologies (476C) as what might be an appropriate alternative if we had to start from a non-metrizable space. The particular geometric properties of Euclidean space which make all these results possible are described in 476H-476I, where I describe concentrating operators based on reflections. The actual theorems 476J-476L and 476O can now almost be mass-produced.

476A Hausdorff metrics Let (X, ρ) be a metric space, and $\mathcal{C}$ the family of closed subsets of X.

(a) For a non-empty subset A of X, write $\rho(x, A) = \inf_{y \in A} \rho(x, y)$ for every $x \in X$. Note that $\rho(x, A) \leq \rho(x, y) + \rho(y, A)$ for all x, $y \in X$, so that $x \mapsto \rho(x, A) : X \to \mathbb{R}$ is 1-Lipschitz.

For E, $F \in \mathcal{C} \setminus \{\emptyset\}$, set

$$\tilde{\rho}(E, F) = \max(\sup_{x \in E} \rho(x, F), \sup_{y \in F} \rho(y, E)).$$

If E, $F \in \mathcal{C} \setminus \{\emptyset\}$ and $z \in X$, then $\rho(z, F) \leq \rho(z, E) + \sup_{x \in E} \rho(x, F)$; from this it is easy to see that $\tilde{\rho}$ is a metric on $\mathcal{C} \setminus \{\emptyset\}$, the **Hausdorff metric**. Observe that $x \mapsto \{x\} : X \to \mathcal{C} \setminus \{\emptyset\}$ is an isometry.

(b) If (X,ρ) is complete so is $(\mathcal{C}\setminus\{\emptyset\},\tilde{\rho})$. **P** Suppose that $\langle F_n\rangle_{n\in\mathbb{N}}$ is a sequence in $\mathcal{C}\setminus\{\emptyset\}$ such that $\tilde{\rho}(F_m,F_n)\le 2^{-m}$ whenever $m\le n$. Set

$$F=\limsup_{n\to\infty}F_n=\bigcap_{n\in\mathbb{N}}\overline{\bigcup_{i\ge n}F_i}.$$

Take any $n\in\mathbb{N}$ and $x\in F_n$. Then we can choose $\langle x_i\rangle_{i\in\mathbb{N}}$ inductively by setting $x_0=x$ and, given $x_i\in F_{n+i}$, taking $x_{i+1}\in F_{n+i+1}$ such that $\rho(x_{i+1},x_i)\le 2^{-n-i+1}$; this is possible because $\rho(x_i,F_{n+i+1})\le\tilde{\rho}(F_{n+i},F_{n+i+1})\le 2^{-n-i}$. Now $\langle x_i\rangle_{i\in\mathbb{N}}$ is Cauchy, so has a limit z in X. For every $m\in\mathbb{N}$,

$$z\in\overline{\{x_i:i\ge m\}}\subseteq\overline{\bigcup_{i\ge m}F_i},$$

so $z\in F$; accordingly

$$\rho(x,F)\le\rho(x,z)\le\textstyle\sum_{i=0}^{\infty}\rho(x_i,x_{i+1})\le 2^{-n+2}.$$

Since F_n is not empty, this shows incidentally that F is not empty and belongs to $\mathcal{C}\setminus\{\emptyset\}$.

Next, $\{y:\rho(y,F_n)\le 2^{-n}\}$ is a closed set including F_i for every $i\ge n$, so includes F. This shows that $\tilde{\rho}(F_n,F)\le\max(2^{-n+2},2^{-n})=2^{-n+2}$. As n is arbitrary, $F=\lim_{n\to\infty}F_n$ in $\mathcal{C}\setminus\{\emptyset\}$. As $\langle F_n\rangle_{n\in\mathbb{N}}$ is arbitrary, $\mathcal{C}\setminus\{\emptyset\}$ is complete under $\tilde{\rho}$. **Q**

(c) If (X,ρ) is totally bounded, so is $(\mathcal{C}\setminus\{\emptyset\},\tilde{\rho})$. **P** Let $\epsilon>0$. Then there is a finite set $I\subseteq X$ such that $\rho(x,I)\le\epsilon$ for every $x\in X$. Set $\mathcal{E}=\mathcal{P}I\setminus\{\emptyset\}$. Then $\mathcal{E}$ is a finite subset of $\mathcal{C}\setminus\{\emptyset\}$. If $F\in\mathcal{C}\setminus\{\emptyset\}$, set $E=\{x:x\in I,\ \rho(x,F)\le\epsilon\}$. Then $\tilde{\rho}(E,F)\le\epsilon$. Thus $\mathcal{C}\setminus\{\emptyset\}$ can be covered by finitely many closed balls of radius ϵ. As ϵ is arbitrary, $(\mathcal{C}\setminus\{\emptyset\},\tilde{\rho})$ is totally bounded. **Q**

(d) It follows that if (X,ρ) is compact, so is $(\mathcal{C}\setminus\{\emptyset\},\tilde{\rho})$ (4A2Jd).

476B Lemma Let (X,ρ) be a metric space, $\mathcal{C}_1$ the set of closed subsets of X, and $\tilde{\rho}$ the Hausdorff metric on $\mathcal{C}\setminus\{0\}$. Let σ be the metric on $X\times X$ defined by setting $\sigma((x_1,x_2),(y_1,y_2))=\max(\rho(x_1,y_1),\rho(x_2,y_2))$, $\mathcal{C}_2$ the set of closed subsets of $X\times X$ and $\tilde{\sigma}$ the Hausdorff metric on $\mathcal{C}_2\setminus\{\emptyset\}$. Then the map $F\mapsto F\times F:\mathcal{C}\setminus\{\emptyset\}\to\mathcal{C}_2\setminus\{\emptyset\}$ is an isometry.

proof If E, $F\in\mathcal{C}\setminus\{\emptyset\}$, then

$$\rho(x,F)=\inf_{y\in F}\rho(x,y)=\inf_{y\in F}\sigma((x,x),(y,y))\le\tilde{\sigma}(E\times E,F\times F)$$

for any $x\in E$, and similarly $\rho(y,E)\le\tilde{\sigma}(E\times E,F\times F)$ for every $y\in F$; so $\tilde{\rho}(E,F)\le\sigma(E\times E,F\times F)$. In the other direction,

$$\begin{aligned}\sigma((x_1,x_2),F\times F)&=\inf_{y_1,y_2\in F}\sigma((x_1,y_1),(x_2,y_2))=\inf_{y_1,y_2\in F}\max(\rho(x_1,y_1),\rho(x_2,y_2))\\&=\max\big(\inf_{y_1\in F}\rho(x_1,y_1),\inf_{y_2\in F}\rho(x_2,y_2)\big)\le\tilde{\rho}(E,F)\end{aligned}$$

for all x_1, $x_2\in E$, and similarly $\sigma((y_1,y_2),E\times E)\le\tilde{\rho}(E,F)$ for all y_1, $y_2\in F$, so $\tilde{\sigma}(E\times E,F\times F)\le\tilde{\rho}(E,F)$.

476C Vietoris topologies Let X be a topological space, and write $\mathcal{C}$ for the family of closed subsets of X.

(a) The **Vietoris topology** on $\mathcal{C}$ is the topology generated by sets of the form

$$\{F:F\in\mathcal{C},\ F\subseteq G\},\quad\{F:F\in\mathcal{C},\ F\cap G\ne\emptyset\}$$

where $G\subseteq X$ is open.

(b) If X is regular, then $\mathcal{C}$ is Hausdorff in its Vietoris topology. **P** Let E_1, $E_2\in\mathcal{C}$ be distinct. Then at least one of $E_1\setminus E_2$, $E_2\setminus E_1$ is non-empty; suppose the former. Take $x\in E_1\setminus E_2$ and an open set G containing x such that $\overline{G}\cap E_2=\emptyset$. Then $\{F:F\in\mathcal{C},\ F\cap G\ne\emptyset\}$ and $\{F:F\in\mathcal{C},\ F\subseteq X\setminus\overline{G}\}$ are disjoint open subsets of $\mathcal{C}$ containing E_1, E_2 respectively. **Q**

(c) If X is regular and normal, then $\mathcal{C}$ is regular in its Vietoris topology. **P** Suppose that $F\in\mathcal{C}$ and that $\mathcal{E}$ is an open subset of $\mathcal{C}$ containing F. Then there must be a finite family $\mathcal{G}$ of open subsets of X and an open subset H_0 of X such that

$$F \subseteq \{E : E \in \mathcal{C},\, E \cap G \neq \emptyset \;\forall\, G \in \mathcal{G},\, E \subseteq H_0\} \subseteq \mathcal{E}.$$

Let H_1 be an open set such that $F \subseteq H_1 \subseteq \overline{H}_1 \subseteq H_0$. For each $G \in \mathcal{G}$ take a point $x_G \in F \cap G$ and an open set G' containing x_G such that $\overline{G'} \subseteq G$. Now consider

$$\mathcal{E}_1 = \{E : E \in \mathcal{C},\, E \cap G' \neq \emptyset \;\forall\, G \in \mathcal{G},\, E \subseteq H_0\},$$

$$\mathcal{E}_2 = \textstyle\bigcup_{G \in \mathcal{G}} \{E : E \in \mathcal{C},\, E \subseteq X \setminus \overline{G'}\} \cup \{E : E \in \mathcal{C},\, E \cap (X \setminus \overline{H}_1) \neq \emptyset\}.$$

Then $\mathcal{E}_1$ and $\mathcal{E}_2$ are disjoint open sets in $\mathcal{C}$, $F \in \mathcal{E}_1$ and $\mathcal{E}_2 \supseteq \mathcal{C} \setminus \mathcal{E}$. As F and $\mathcal{E}$ are arbitrary, $\mathcal{C}$ is regular. **Q**

(d) A variant of the Vietoris topology will be useful in §495. I will say that the **k-Vietoris topology** on $\mathcal{C}$ is the topology generated by sets of the form

$$\{F : F \in \mathcal{C},\, F \cap G \neq \emptyset\}, \quad \{F : F \in \mathcal{C},\, F \cap K = \emptyset\}$$

where $G \subseteq X$ is open and $K \subseteq X$ is compact. Now we have the following easy results.

(i) $\mathcal{C}$ is compact in its k-Vietoris topology. **P** Let $\mathfrak{F}$ be an ultrafilter on $\mathcal{C}$. Set $C_0 = \bigcap_{\mathcal{E} \in \mathfrak{F}} \overline{\bigcup \mathcal{E}}$. ($\alpha$) If $G \subseteq X$ is open and $G \cap C_0 \neq \emptyset$, set $\mathcal{E} = \{C : C \in \mathcal{C},\, C \cap G = \emptyset\}$. Then $\overline{\bigcup \mathcal{E}}$ does not meet G, so does not include C_0, and $\mathcal{E} \notin \mathfrak{F}$. Accordingly $\{C : C \cap G \neq \emptyset\} = \mathcal{C} \setminus \mathcal{E}$ belongs to $\mathcal{F}$. (β) If $K \subseteq X$ is compact and $C_0 \cap K = \emptyset$, then $\{K \cap \overline{\bigcup \mathcal{E}} : \mathcal{E} \in \mathfrak{F}\}$ is a downwards-directed family of relatively closed subsets of K with empty intersection so must contain the empty set, and there is an $\mathcal{E} \in \mathfrak{F}$ such that $K \cap C = \emptyset$ for every $C \in \mathcal{E}$, that is, $\{C : C \cap K = \emptyset\}$ belongs to $\mathcal{F}$. (γ) By 4A2B(a-v), $\mathfrak{F} \to C_0$. As $\mathfrak{F}$ is arbitrary, $\mathcal{C}$ is compact. **Q**

(ii) If X is Hausdorff, the k-Vietoris topology is coarser than the Vietoris topology. If X is compact and Hausdorff the two topologies agree; in particular, the Vietoris topology on $\mathcal{C}$ is compact.

(iii) If X is locally compact and Hausdorff, the k-Vietoris topology on X is Hausdorff. **P** Let C_1, $C_2 \in \mathcal{C}$ be distinct. Then there is a point belonging to one and not the other; suppose that $x \in C_1 \setminus C_2$. Because X is locally compact and Hausdorff, there is a relatively compact open set G such that $x \in G$ and $\overline{G} \cap C_2 = \emptyset$. Now $\{C : C \cap G \neq \emptyset\}$ and $\{C : C \cap \overline{G} = \emptyset\}$ are disjoint open sets in $\mathcal{C}$ containing C_1, C_2 respectively. **Q**

476D Proposition Let (X, ρ) be a metric space, and $\tilde{\rho}$ the Hausdorff metric on $\mathcal{C} \setminus \{\emptyset\}$, where $\mathcal{C}$ is the family of closed subsets of X. Write $\mathcal{K} \subseteq \mathcal{C}$ for the family of compact subsets of X.

(a) If μ is a totally finite topological measure on X, then $\mu\restriction\mathcal{C} \setminus \{\emptyset\}$ is upper semi-continuous.

(b) If μ is a locally finite topological measure on X, then $\mu\restriction\mathcal{K} \setminus \{\emptyset\}$ is upper semi-continuous for the subspace topology on $\mathcal{K} \setminus \{\emptyset\}$.

(c) If μ is a topological measure on X and f is a non-negative μ-integrable real-valued function, then $F \mapsto \int_F f d\mu : \mathcal{C} \setminus \{\emptyset\} \to \mathbb{R}$ is upper semi-continuous.

proof (a) If $F \in \mathcal{C} \setminus \{\emptyset\}$ and $\mu F < \alpha$, then for each $n \in \mathbb{N}$ set $F_n = \{x : \rho(x, F) \leq 2^{-n}\}$. Since $\langle F_n \rangle_{n \in \mathbb{N}}$ is a non-decreasing sequence of closed sets with intersection F, and μ is totally finite, there is an n such that $\mu F_n < \alpha$. If now we take $E \in \mathcal{C} \setminus \{\emptyset\}$ such that $\tilde{\rho}(E, F) \leq 2^{-n}$, then $E \subseteq F_n$ so $\mu E < \alpha$. As F and α are arbitrary, $\mu\restriction\mathcal{C} \setminus \{\emptyset\}$ is upper semi-continuous.

(b) The argument is the same as in (a), with one refinement. If $K \in \mathcal{K} \setminus \{\emptyset\}$ and we set $F_n = \{x : \rho(x, K) \leq 2^{-n}\}$, then we do not know that every F_n has finite measure. However, since μ is locally finite, every point of K has an open neighbourhood of finite measure; as K is compact, we can cover it by finitely many open sets of finite measure, and $K \subseteq G$ where $G \subseteq X$ is open and $\mu G < \infty$. Next, the function $x \mapsto \rho(x, X \setminus G)$ is continuous and strictly positive on K, so has a non-zero lower bound on K, and there is some $m \in \mathbb{N}$ such that $\rho(x, X \setminus G) > 2^{-m}$ for every $x \in K$, in which case $F_m \subseteq G$. It follows now that there is some $n \geq m$ such that $\mu F_n < \alpha$, and we can continue as before.

(c) Apply (a) to the indefinite-integral measure over μ defined by f.

476E Proposition Let X be a topological space, and $\mathcal{C}$ the family of closed subsets of X, with the Vietoris topology. Write $\mathcal{K} \subseteq \mathcal{C}$ for the family of closed compact subsets of X.

(a) If μ is a totally finite topological measure on X which is inner regular with respect to the closed sets, then $\mu\restriction\mathcal{C}$ is upper semi-continuous.

(b) If μ is a locally finite topological measure on X which is inner regular with respect to the closed sets, then $\mu\restriction\mathcal{K}$ is upper semi-continuous.

proof (a) Suppose that $F \in \mathcal{C}$ and that $\mu F < \alpha$. Because μX is finite, there is a closed set $F_1 \subseteq X \setminus F$ such that $\mu F_1 > \mu X - \alpha$, so that $\mu(X \setminus F_1) < \alpha$. Now $\mathcal{E} = \{E : E \in \mathcal{C}, E \subseteq X \setminus F_1\}$ is an open set containing F, and $\mu E < \alpha$ for every $E \in \mathcal{E}$. As F and α are arbitrary, $\mu\restriction\mathcal{C}$ is upper semi-continuous.

(b) If $K \in \mathcal{K}$ and $\mu K < \alpha$ then, because μ is locally finite, there is an open set $G \supseteq K$ such that $\mu G < \infty$. Now there is a closed set $F_1 \subseteq G$ such that $\mu F_1 > \mu G - \alpha$, so that $\mathcal{L} = \{L : L \in \mathcal{K}, L \subseteq G \setminus F_1\}$ is an open subset of $\mathcal{K}$ and $\mu L < \alpha$ for every $L \in \mathcal{L}$. As K and α are arbitrary, $\mu\restriction\mathcal{K}$ is upper semi-continuous.

476F Proposition Let (X, ρ) be a metric space, and $\tilde{\rho}$ the Hausdorff metric on $\mathcal{C} \setminus \{\emptyset\}$, where $\mathcal{C}$ is the family of closed subsets of X. For non-empty sets $A \subseteq X$ and $\epsilon > 0$, set $U(A, \epsilon) = \{x : x \in X, \rho(x, A) < \epsilon\}$. Then for any τ-additive topological measure μ on X, the function

$$(F, \epsilon) \mapsto \mu U(F, \epsilon) : (\mathcal{C} \setminus \{\emptyset\}) \times]0, \infty[\to [0, \infty]$$

is lower semi-continuous.

proof Suppose that $\alpha \in]0, \infty[$ and that $F_0 \in \mathcal{C} \setminus \{\emptyset\}$, $\epsilon_0 \in]0, \infty[$ are such that $\mu U(F_0, \epsilon_0) > \alpha$. Then $\{U(I, \delta) : I \in [F_0]^{<\omega}, \delta < \epsilon_0\}$ is an upwards-directed family of open sets with union $U(F_0, \epsilon_0)$. Because μ is τ-additive, there are $\delta < \epsilon_0$, $I \in [F_0]^{<\omega}$ such that $\mu U(I, \delta) > \alpha$. Now suppose that $F \in \mathcal{C} \setminus \{\emptyset\}$ and ϵ are such that $\tilde{\rho}(F, F_0) < \frac{1}{2}(\epsilon_0 - \delta)$ and $\epsilon > \frac{1}{2}(\delta + \epsilon_0)$. Then $\rho(x, F) < \frac{1}{2}(\epsilon_0 - \delta) < \epsilon - \delta$ for every $x \in I$, so $U(I, \delta) \subseteq U(F, \epsilon)$ and $\mu U(F, \epsilon) > \alpha$. As α, F_0 and ϵ_0 are arbitrary, $(F, \epsilon) \mapsto \mu U(F, \epsilon)$ is lower semi-continuous.

Remark Recall that all 'ordinary' topological measures on metric spaces are τ-additive; see 438J.

476G Proposition Let (X, ρ) be a non-empty compact metric space, and suppose that its isometry group G acts transitively on X. Then X has a unique G-invariant Radon probability measure μ, which is strictly positive.

proof By 441G, G, with its topology of pointwise convergence, is a compact topological group, and the action of G on X is continuous. So 443Td gives the result.

476H Concentration by partial reflection The following construction will be used repeatedly in the rest of the section. Let X be an inner product space. (In this section, X will be usually be $\mathbb{R}^r$, but in 493J it will be helpful to be able to speak of abstract Hilbert spaces.) For any unit vector $e \in X$ and any $\alpha \in \mathbb{R}$, write $R_{e\alpha} : X \to X$ for the reflection in the hyperplane $V_{e\alpha} = \{x : x \in X, (x|e) = \alpha\}$, so that $R_{e\alpha}(x) = x + 2(\alpha - (x|e))e$ for every $x \in X$. Next, for any $A \subseteq X$, we can define a set $\psi_{e\alpha}(A)$ by setting

$$\begin{aligned}\psi_{e\alpha}(A) &= \{x : x \in A, (x|e) \geq \alpha\} \cup \{x : x \in A, (x|e) < \alpha, R_{e\alpha}(x) \in A\} \\ &\qquad \cup \{x : x \in \mathbb{R}^r \setminus A, (x|e) \geq \alpha, R_{e\alpha}(x) \in A\} \\ &= (W \cap (A \cup R_{e\alpha}[A])) \cup (A \cap R_{e\alpha}[A] \setminus W),\end{aligned}$$

where W is the half-space $\{x : (x|e) \geq \alpha\}$. Geometrically, we construct $\psi_{e\alpha}(A)$ by moving those points of A on the 'wrong' side of the hyperplane $V_{e\alpha}$ to their reflections, provided those points are not already occupied. We have the following facts.

(a) For non-empty $A \subseteq X$ and $\epsilon > 0$, set $U(A, \epsilon) = \{x : \rho(x, A) < \epsilon\}$, where ρ is the standard metric on X. Now $U(\psi_{e\alpha}(A), \epsilon) \subseteq \psi_{e\alpha}(U(A, \epsilon))$. **P** Take $x \in U(\psi_{e\alpha}(A), \epsilon)$. Then there is a $y \in \psi_{e\alpha}(A)$ such that $\|x - y\| < \epsilon$.

case 1 Suppose $(x|e) \geq \alpha$. If $x \in U(A,\epsilon)$ then certainly $x \in \psi_{e\alpha}(U(A,\epsilon))$. Otherwise, because $\|x-y\| < \epsilon$, $y \notin A$, so $R_{e\alpha}(y) \in A$. But $\|R_{e\alpha}(x) - R_{e\alpha}(y)\| = \|x-y\| < \epsilon$, so $R_{e\alpha}(x) \in U(A,\epsilon)$ and $x \in \psi_{e\alpha}(U(A,\epsilon))$.

case 2a Suppose $(x|e) < \alpha$, $(y|e) \geq \alpha$. Then

$$\|R_{e\alpha}(x) - y\| = \|x - R_{e\alpha}(y)\| \leq \|R_{e\alpha}(x) - R_{e\alpha}(y)\| = \|x-y\| < \epsilon.$$

At least one of y, $R_{e\alpha}(y)$ belongs to A, so both x and $R_{e\alpha}(x)$ belong to $U(A,\epsilon)$ and $x \in \psi_{e\alpha}(U(A,\epsilon))$.

case 2b Suppose $(x|e) < \alpha$ and $(y|e) < \alpha$. In this case, both y and $R_{e\alpha}(y)$ belong to A, so both x and $R_{e\alpha}(x)$ belong to $U(A,\epsilon)$ and again $x \in \psi_{e\alpha}(U(A,\epsilon))$.

Thus $x \in \psi_{e\alpha}(U(A,\epsilon))$ in all cases; as x is arbitrary, we have the result. **Q**

(b) If $F \subseteq X$ is closed, then $\psi_{e\alpha}(F)$ is closed. **P** Use the second formula for $\psi_{e\alpha}(F)$. **Q**

476I Lemma Let X be an inner product space, $e \in X$ a unit vector and $\alpha \in \mathbb{R}$. Let $R = R_{e\alpha} : X \to X$ be the reflection operator, and $\psi = \psi_{e\alpha} : \mathcal{P}X \to \mathcal{P}X$ the associated transformation, as described in 476H. For $x \in A \subseteq X$, define

$$\begin{aligned}\phi_A(x) &= x \text{ if } (x|e) \geq \alpha,\\ &= x \text{ if } (x|e) < \alpha \text{ and } R(x) \in A,\\ &= R(x) \text{ if } (x|e) < \alpha \text{ and } R(x) \notin A.\end{aligned}$$

Let ν be a topological measure on X which is R-invariant, that is, ν is the image measure νR^{-1}.

(a) For any $A \subseteq X$, $\phi_A : A \to \psi(A)$ is a bijection. If $\alpha < 0$, then $\|\phi_A(x)\| \leq \|x\|$ for every $x \in A$, with $\|\phi_A(x)\| < \|x\|$ iff $(x|e) < \alpha$ and $R(x) \notin A$.

(b) If $E \subseteq X$ is measured by ν, then $\psi(E)$ is measurable and $\nu\psi(E) = \nu E$; moreover, ϕ_E is a measure space isomorphism for the subspace measures on E and $\psi(E)$.

(c) If $\alpha < 0$ and $E \subseteq X$ is measurable, then $\int_E \|x\|\nu(dx) \geq \int_{\psi(E)} \|x\|\nu(dx)$, with equality iff $\{x : x \in E,\ (x|e) < \alpha,\ R(x) \notin E\}$ is negligible.

(d) Suppose that X is separable. Let λ be the c.l.d. product measure of ν with itself on $X \times X$. If $\alpha \leq 0$ and $E \subseteq X$ is measurable, then

$$\int_{E\times E} \|x-y\|\lambda(d(x,y)) \geq \int_{\psi(E)\times\psi(E)} \|x-y\|\lambda(d(x,y)).$$

(e) Now suppose that $X = \mathbb{R}^r$. Then $\nu(\partial^*\psi(A)) \leq \nu(\partial^* A)$ for every $A \subseteq \mathbb{R}^r$, where $\partial^* A$ is the essential boundary of A (definition: 475B).

proof (a) That $\phi_A : A \to \psi(A)$ is a bijection is immediate from the definitions of ψ and ϕ_A. If $\alpha < 0$, then for any $x \in A$ either $\phi_A(x) = x$ or $(x|e) < \alpha$ and $R(x) \notin A$. In the latter case

$$\begin{aligned}\|\phi_A(x)\|^2 = \|R(x)\|^2 &= \|x + 2\gamma e\|^2\\ \text{(where } \gamma = \alpha - (x|e) > 0)\\ &= \|x\|^2 + 4\gamma(x|e) + 4\gamma^2 = \|x\|^2 + 4\gamma\alpha < \|x\|^2,\end{aligned}$$

so $\|\phi_A(x)\| < \|x\|$.

(b) If we set

$$E_1 = \{x : x \in E,\ (x|e) \geq \alpha\},$$

$$E_2 = \{x : x \in E, (x|e) < \alpha,\ R_{e\alpha}(x) \in E\},$$

$$E_3 = \{x : x \in E,\ (x|e) < \alpha,\ R_{e\alpha}(x) \notin E\},$$

$$E_4 = \{x : x \in \mathbb{R}^r \setminus E,\ (x|e) > \alpha,\ R_{e\alpha}(x) \in E\},$$

then E_1, E_2, E_3 and E_4 are disjoint measurable sets, $E = E_1 \cup E_2 \cup E_3$, $\psi(E) = E_1 \cup E_2 \cup E_4$ and $\phi_E{\restriction}E_3 = R{\restriction}E_3$ is a measure space isomorphism for the subspace measures on E_3 and E_4.

(c) By (a),

$$\int_E \|x\|\nu(dx) \geq \int_E \|\phi_E(x)\|\nu(dx) = \int_{\psi(E)} \|x\|\nu(dx)$$

by 235Ic, because $\phi_E : E \to \psi(E)$ is inverse-measure-preserving, with equality only when

$$\{x : \|x\| > \|\phi_E(x)\|\} = \{x : x \in E, (x|e) < \alpha, R(x) \notin E\}$$

is negligible.

(d) Note first that if Λ is the domain of λ then Λ includes the Borel algebra of $X \times X$ (because X is second-countable, so this is just the σ-algebra generated by products of Borel sets, by 4A3G); so that $(x, y) \mapsto \|x - y\|$ is Λ-measurable, and the integral is defined in $[0, \infty]$. Now consider the sets

$$W_1 = \{(x, y) : x \in E, y \in E, R(x) \notin E, R(y) \in E, (x|e) < \alpha, (y|e) < \alpha\},$$

$$W_1' = \{(x, y) : x \in E, y \in E, R(x) \notin E, R(y) \in E, (x|e) < \alpha, (y|e) > \alpha\},$$

$$W_2 = \{(x, y) : x \in E, y \in E, R(x) \in E, R(y) \notin E, (x|e) < \alpha, (y|e) < \alpha\},$$

$$W_2' = \{(x, y) : x \in E, y \in E, R(x) \in E, R(y) \notin E, (x|e) > \alpha, (y|e) < \alpha\}.$$

Then $(x, y) \mapsto (x, R(y)) : W_1' \to W_1$ is a measure space isomorphism for the subspace measures induced on W_1 and W_1' by λ, so

$$\begin{aligned}\int_{W_1} \|\phi_E(x) - \phi_E(y)\|\lambda(d(x, y)) &= \int_{W_1} \|R(x) - y\|\lambda(d(x, y)) \\ &= \int_{W_1'} \|R(x) - R(y)\|\lambda(d(x, y)) \\ &= \int_{W_1'} \|x - y\|\lambda(d(x, y)).\end{aligned}$$

Similarly,

$$\begin{aligned}\int_{W_1'} \|\phi_E(x) - \phi_E(y)\|\lambda(d(x, y)) &= \int_{W_1'} \|R(x) - y\|\lambda(d(x, y)) \\ &= \int_{W_1} \|R(x) - R(y)\|\lambda(d(x, y)) \\ &= \int_{W_1} \|x - y\|\lambda(d(x, y)).\end{aligned}$$

So we get

$$\int_{W_1 \cup W_1'} \|\phi_E(x) - \phi_E(y)\|\lambda(d(x, y)) = \int_{W_1 \cup W_1'} \|x - y\|\lambda(d(x, y)).$$

In the same way, $(x, y) \mapsto (R(x), y)$ is an isomorphism of the subspace measures on W_2 and W_2', and we have

$$\int_{W_2 \cup W_2'} \|\phi_E(x) - \phi_E(y)\|\lambda(d(x, y)) = \int_{W_2 \cup W_2'} \|x - y\|\lambda(d(x, y)).$$

On the other hand, for all $(x, y) \in (E \times E) \setminus (W_1 \cup W_1' \cup W_2 \cup W_2')$, we have $\|\phi_E(x) - \phi_E(y)\| \leq \|x - y\|$. (Either x and y are both left fixed by ϕ, or both are moved, or one is on the reflecting hyperplane, or one is moved to the same side of the reflecting hyperplane as the other.) So we get

$$\begin{aligned}\int_{E \times E} \|x - y\|\lambda(d(x, y)) &\geq \int_{E \times E} \|\phi_E(x) - \phi_E(y)\|\lambda(d(x, y)) \\ &= \int_{\psi(E) \times \psi(E)} \|x - y\|\lambda(d(x, y))\end{aligned}$$

because $(x, y) \mapsto (\phi_E(x), \phi_E(y))$ is an inverse-measure-preserving transformation for the subspace measures on $E \times E$ and $\psi(E) \times \psi(E)$.

(e)(i) Because R is both an isometry and a measure space automorphism, $\mathrm{cl}^*R[A] = R[\mathrm{cl}^*A]$ and $\mathrm{int}^*R[A] = R[\mathrm{int}^*A]$, where cl^*A and int^*A are the essential closure and the essential interior of A, as in 475B. Recall that cl^*A, int^*A and ∂^*A are all Borel sets (475Cc), so that ∂^*A and $\partial^*\psi(A)$ are measurable.

(ii) Suppose that $x.e = \alpha$. Then $x \in \partial^*\psi(A)$ iff $x \in \partial^*A$. **P** It is easy to check that $B(x,\delta) \cap \psi(A) = \psi(B(x,\delta) \cap A)$ for any $\delta > 0$, so that $\nu^*(B(x,\delta) \cap \psi(A)) = \nu^*(\psi(B(x,\delta) \cap A))$ for every $\delta > 0$ and $x \in \mathrm{cl}^*A$ iff $x \in \mathrm{cl}^*\psi(A)$. If $x = R(x) \in \mathrm{int}^*A$, then $x \in \mathrm{int}^*R[A]$ so $x \in \mathrm{int}^*(A \cap R[A])$ (475Cd) and $x \in \mathrm{int}^*\psi(A)$. If $x \in \mathrm{int}^*\psi(A)$ then $x \in \mathrm{int}^*(R[\psi(A)] \cap \psi(A)) \subseteq \mathrm{int}^*A$. **Q**

(iii) If $x \in \partial^*\psi(A) \setminus \partial^*A$ then $R(x) \in \partial^*A \setminus \partial^*\psi(A)$. **P** By (ii), $x.e \neq \alpha$.

case 1 Suppose that $x.e > \alpha$. Setting $\delta = x.e - \alpha$, we see that $U(x,\delta) \cap \psi(A) = U(x,\delta) \cap (A \cup R[A])$, while $U(R(x),\delta) \cap \psi(A) = U(R(x),\delta) \cap A \cap R[A]$. Since $x \notin \mathrm{int}^*\psi(A)$, $x \notin \mathrm{int}^*(A \cup R[A])$ and $x \notin \mathrm{int}^*A$; since x also does not belong to ∂^*A, $x \notin \mathrm{cl}^*A$. However, $x \in \mathrm{cl}^*(A \cup R[A]) = \mathrm{cl}^*A \cup \mathrm{cl}^*R[A]$ (475Cd), so $x \in \mathrm{cl}^*R[A]$ and $R(x) \in \mathrm{cl}^*A$. Next, $x \notin \mathrm{int}^*R[A]$, so $R(x) \notin \mathrm{int}^*A$ and $R(x) \in \partial^*A$. Since $x \notin \mathrm{cl}^*A$, $R(x) \notin \mathrm{cl}^*R[A]$ and $R(x) \notin \mathrm{cl}^*\psi(A)$; so $R(x) \in \partial^*A \setminus \partial^*\psi(A)$.

case 2 Suppose that $x.e < \alpha$. This time, set $\delta = \alpha - x.e$, so that $U(x,\delta) \cap \psi(A) = U(x,\delta) \cap A \cap R[A]$ and $U(R(x),\delta) \cap \psi(A) = U(R(x),\delta) \cap (A \cup R[A])$. As $x \in \mathrm{cl}^*\psi(A)$, $x \in \mathrm{cl}^*(A \cap R[A])$ and $R(x) \in \mathrm{cl}^*A$. Also $x \in \mathrm{cl}^*A$; as $x \notin \partial^*A$, $x \in \mathrm{int}^*A$, $R(x) \in \mathrm{int}^*R[A]$ and $R(x) \in \mathrm{int}^*\psi(A)$, so that $R(x) \notin \partial^*\psi(A)$. Finally, we know that $x \in \mathrm{int}^*A$ but $x \notin \mathrm{int}^*(A \cap R[A])$ (because $x \notin \mathrm{int}^*\psi(A)$; it follows that $x \notin \mathrm{int}^*R[A]$ so $R(x) \notin \mathrm{int}^*A$ and $R(x) \in \partial^*A \setminus \partial^*\psi(A)$.

Thus all possibilities are covered and we have the result. **Q**

(iv) What this means is that if we set $E = \partial^*\psi(A) \setminus \partial^*A$ then $R[E] \subseteq \partial^*A \setminus \partial^*\psi(A)$. So

$$\nu\partial^*\psi(A) = \nu E + \nu(\partial^*\psi(A) \cap \partial^*A) = \nu R[E] + \nu(\partial^*\psi(A) \cap \partial^*A) \leq \nu\partial^*A,$$

as required in (e). This ends the proof of the lemma.

476J Theorem Let $r \geq 1$ be an integer, and let μ be Lebesgue measure on $\mathbb{R}^r$. For non-empty $A \subseteq \mathbb{R}^r$ and $\epsilon > 0$, write $U(A,\epsilon)$ for $\{x : \rho(x,A) < \epsilon\}$, where ρ is the Euclidean metric on $\mathbb{R}^r$. If μ^*A is finite, then $\mu U(A,\epsilon) \geq \mu U(B_A,\epsilon)$, where B_A is the closed ball with centre $\mathbf{0}$ and measure μ^*A.

proof (a) To begin with, suppose that A is bounded. Set $\gamma = \mu^*A$, $\beta = \mu U(A,\epsilon)$. If $\gamma = 0$ then (because $A \neq \emptyset$)

$$\mu U(A,\epsilon) \geq \mu U(\{\mathbf{0}\},\epsilon) = \mu U(B_A,\epsilon),$$

and we can stop. So let us suppose henceforth that $\gamma > 0$. Let $M \geq 0$ be such that $A \subseteq B(\mathbf{0},M)$, and consider the family

$$\mathcal{F} = \{F : F \in \mathcal{C} \setminus \{\emptyset\},\ \mu F \geq \gamma,\ \mu U(F,\epsilon) \leq \beta\},$$

where $\mathcal{C}$ is the family of closed subsets of $B(\mathbf{0},M)$. Because $U(\overline{A},\epsilon) = U(A,\epsilon)$, $\overline{A} \in \mathcal{F}$ and $\mathcal{F}$ is non-empty. By 476D and 476F, $\mathcal{F}$ is closed for the Hausdorff metric on $\mathcal{C} \setminus \{\emptyset\}$, therefore compact, by 476Ad, because $B(\mathbf{0},M)$ is compact. Next, the function

$$F \mapsto \int_F (M - \|x\|)\mu(dx) : \mathcal{C} \setminus \{\emptyset\} \to [0,\infty[$$

is upper semi-continuous, by 476Dc. It therefore attains its supremum on $\mathcal{F}$ at some $F_0 \in \mathcal{F}$ (4A2Gk). Let $F_1 \subseteq F_0$ be a closed self-supporting set of the same measure as F_0; then $U(F_1,\epsilon) \subseteq U(F_0,\epsilon)$ and $\mu F_1 = \mu F_0$, so $F_1 \in \mathcal{F}$; also

$$\int_{F_1} M - \|x\|\mu(dx) = \int_{F_0} M - \|x\|\mu(dx) \geq \int_F M - \|x\|\mu(dx)$$

for every $F \in \mathcal{F}$.

(b) Now F_1 is a ball with centre $\mathbf{0}$. **P?** Suppose, if possible, otherwise. Then there are $x_1 \in F_1$ and $x_0 \in \mathbb{R}^r \setminus F_1$ such that $\|x_0\| < \|x_1\|$. Set $e = \frac{1}{\|x_0 - x_1\|}(x_0 - x_1)$, so that e is a unit vector, and $\alpha = \frac{1}{2}e.(x_0 + x_1)$; then

$$\alpha = \frac{1}{2\|x_0 - x_1\|}(x_0 - x_1).(x_0 + x_1) = \frac{1}{2\|x_0 - x_1\|}(\|x_0\|^2 - \|x_1\|^2) < 0.$$

Define $R = R_{e\alpha} : \mathbb{R}^r \to \mathbb{R}^r$ and $\psi = \psi_{e\alpha}$ as in 476H. Set $F = \psi(F_1)$. Then F is closed (476Hb) and $\mu F = \mu F_1 \geq \mu^* A$ (476Ib). Also $U(F,\epsilon) \subseteq \psi(U(F_1,\epsilon))$ (476Ha), so

$$\mu U(F,\epsilon) \leq \mu(\psi(U(F_1,\epsilon)) = \mu U(F_1,\epsilon) \leq \beta$$

and $F \in \mathcal{F}$. It follows that $\int_F M - \|x\|\mu(dx) \leq \int_{F_1} M - \|x\|\mu(dx)$; as $\mu F = \mu F_1$, $\int_F \|x\|\mu(dx) \geq \int_{F_1} \|x\|\mu(dx)$. By 476Ic, $G = \{x : x \in F_1, x.e < \alpha, R(x) \notin F_1\}$ is negligible. But G contains x_1 and is relatively open in F_1, and F_1 is supposed to be self-supporting; so this is impossible. **XQ**

(c) Since $\mu F_1 \geq \gamma$, $F_1 \supseteq B_A$, and

$$\mu U(B_A,\epsilon) \leq \mu U(F_1,\epsilon) \leq \beta = \mu U(A,\epsilon).$$

So we have the required result for bounded A. In general, given an unbounded set A of finite measure, let δ be the radius of B_A; then

$$\begin{aligned}\mu U(B_A,\epsilon) &= \mu B(\mathbf{0},\delta+\epsilon) = \sup_{\alpha<\delta} \mu B(\mathbf{0},\alpha+\epsilon)\\ &\leq \sup_{A'\subseteq A \text{ is bounded}} \mu U(B_{A'},\epsilon) \leq \sup_{A'\subseteq A \text{ is bounded}} \mu U(A,\epsilon) = \mu U(A,\epsilon)\end{aligned}$$

because $\{U(A',\epsilon) : A' \subseteq A \text{ is bounded}\}$ is an upwards-directed family of open sets with union $U(A,\epsilon)$, and μ is τ-additive. So the theorem is true for unbounded A as well.

476K Theorem Let $r \geq 1$ be an integer, and let μ be Lebesgue measure on $\mathbb{R}^r$; write λ for the product measure on $\mathbb{R}^r \times \mathbb{R}^r$. For any measurable set $E \subseteq \mathbb{R}^r$ of finite measure, write B_E for the closed ball with centre $\mathbf{0}$ and the same measure as E. Then

$$\int_{E\times E} \|x-y\|\lambda(d(x,y)) \geq \int_{B_E\times B_E} \|x-y\|\lambda(d(x,y)).$$

proof (a) Suppose for the moment that E is compact and not empty, and that $\epsilon > 0$. Let $M \geq 0$ be such that $\|x\| \leq M$ for every $x \in E$. For non-empty sets $A \subseteq \mathbb{R}^r$ set $U(A,\epsilon) = \{x : \rho(x,A) < \epsilon\}$, where ρ is Euclidean distance on $\mathbb{R}^r$. Set $\beta = \int_{U(E,\epsilon)\times U(E,\epsilon)} \|x-y\|\lambda(d(x,y))$. Let $\mathcal{F}$ be the family of non-empty closed subsets F of the ball $B(\mathbf{0},M) = \{x : \|x\| \leq M\}$ such that $\mu F \geq \mu E$ and $\int_{U(F,\epsilon)\times U(F,\epsilon)} \|x-y\|\lambda(d(x,y)) \leq \beta$. Then $\mathcal{F}$ is compact for the Hausdorff metric on the family $\mathcal{C}\setminus\{\emptyset\}$ of non-empty closed subsets of $B(\mathbf{0},M)$. **P** We know from 476Ad that $\mathcal{C}\setminus\{\emptyset\}$ is compact, and from 476Da that $\{F : \mu F \geq \mu E\}$ is closed. To see that $\mathcal{F}$ is closed, consider the metric σ on $\mathbb{R}^r \times \mathbb{R}^r$ defined by setting $\sigma((x,y),(x',y')) = \max(\|x-x'\|, \|y-y'\|)$, and the measure ν which is the indefinite-integral measure over λ defined by the function $(x,y) \mapsto \|x-y\|$. Writing $\mathcal{C}_2$ for the family of non-empty closed subsets of $\mathbb{R}^r$, the map $F \mapsto F\times F : \mathcal{C}\setminus\{\emptyset\} \to \mathcal{C}_2\setminus\{\emptyset\}$ is continuous (476B) and the map $W \mapsto \nu U(W,\epsilon) : \mathcal{C}_2\setminus\{\emptyset\} \to \leftarrow$ is lower semi-continuous, where $U(W,\epsilon) = \{(x,y) : \sigma((x,y),W) < \epsilon\}$ (476F). But this means that $F \mapsto \int_{U(F,\epsilon)\times U(F,\epsilon)} \|x-y\|\lambda(d(x,y))$ is lower semi-continuous, and $\{F : \int_{U(F,\epsilon)\times U(F,\epsilon)} \|x-y\|\lambda(d(x,y)) \leq \beta\}$ is closed. Thus $\mathcal{F}$ is a closed subset of $\mathcal{C}\setminus\{\emptyset\}$ and is compact. **Q**

(b) Since $E \in \mathcal{F}$, $\mathcal{F}$ is not empty. By 476Dc, there is an $F_0 \in \mathcal{F}$ such that $\int_{F_0} M - \|x\|\mu(dx) \geq \int_F M - \|x\|\mu(dx)$ for every $F \in \mathcal{F}$. Let $F_1 \subseteq F_0$ be a closed self-supporting set of the same measure; then $U(F_1,\epsilon) \subseteq U(F_0,\epsilon)$, so $\int_{U(F_1,\epsilon)\times U(F_1,\epsilon)} \|x-y\|\lambda(d(x,y)) \leq \beta$ and $F_1 \in \mathcal{F}$; also

$$\int_{F_1} M - \|x\|\mu(dx) = \int_{F_0} M - \|x\|\mu(dx) \geq \int_F M - \|x\|\mu(dx)$$

for every $F \in \mathcal{F}$.

Now F_1 is a ball with centre $\mathbf{0}$. **P?** Suppose, if possible, otherwise. Then (just as in the proof of 476K) there are $x_1 \in F_1$ and $x_0 \in \mathbb{R}^r\setminus F_1$ such that $\|x_1\| > \|x_0\|$. Set $e = \frac{1}{\|x_0-x_1\|}(x_0-x_1)$ and $\alpha = \frac{1}{2}e.(x_0+x_1) < 0$. Define $R = R_{e\alpha} : \mathbb{R}^r \to \mathbb{R}^r$ and $\psi = \psi_{e\alpha}$ as in 476H. Set $F = \psi(F_1)$. Then F is closed and $\mu F = \mu F_1 \geq \mu E$ and $U(F,\epsilon) \subseteq \psi(U(F_1,\epsilon))$. So

$$\begin{aligned}\int_{U(F,\epsilon)\times U(F,\epsilon)} \|x-y\|\lambda(d(x,y)) &\leq \int_{\psi(U(F_1,\epsilon))\times\psi(U(F_1,\epsilon))} \|x-y\|\lambda(d(x,y)) \\ &\leq \int_{U(F_1,\epsilon))\times U(F_1,\epsilon)} \|x-y\|\lambda(d(x,y)) \\ &\leq \beta. \end{aligned} \tag{476Id}$$

This means that $F \in \mathcal{F}$. Accordingly $\int_{F_1} M-\|x\|\mu(dx) \geq \int_F M-\|x\|\mu(dx)$; since $\mu F = \mu F_1$, $\int_{F_1}\|x\|\mu(dx) \leq \int_F \|x\|\mu(dx)$. By 476Ic, $G = \{x : x \in F_1, x\boldsymbol{.}e < \alpha, R(x) \notin F_1\}$ must be negligible. But G contains x_1 and is relatively open in F_1, and F_1 is supposed to be self-supporting; so this is impossible. **XQ**

(c) Since $\mu F_1 \geq \mu E$, $F_1 \supseteq B_E$, and

$$\begin{aligned}\int_{B_E\times B_E} \|x-y\|\lambda(d(x,y)) &\leq \int_{U(F_1,\epsilon)\times U(F_1,\epsilon)} \|x-y\|\lambda(d(x,y)) \\ &\leq \beta = \int_{U(E,\epsilon)\times U(E,\epsilon)} \|x-y\|\lambda(d(x,y)).\end{aligned}$$

At this point, recall that ϵ was arbitrary. Since E is compact,

$$\begin{aligned}\int_{E\times E} \|x-y\|\lambda(d(x,y)) &= \inf_{\epsilon>0} \int_{U(E,\epsilon)\times U(E,\epsilon)} \|x-y\|\lambda(d(x,y)) \\ &\geq \int_{B_E\times B_E} \|x-y\|\lambda(d(x,y)).\end{aligned}$$

(d) Thus the result is proved for non-empty compact sets E. In general, given a measurable set E of finite measure, then if E is negligible the result is trivial; and otherwise, writing δ for the radius of B_E,

$$\begin{aligned}\int_{B_E\times B_E} \|x-y\|\lambda(d(x,y)) &= \sup_{\alpha<\delta} \int_{B(\mathbf{0},\alpha)\times B(\mathbf{0},\alpha)} \|x-y\|\lambda(d(x,y)) \\ &\leq \sup_{K\subseteq E \text{ is compact}} \int_{B_K\times B_K} \|x-y\|\lambda(d(x,y)) \\ &\leq \sup_{K\subseteq E \text{ is compact}} \int_{K\times K} \|x-y\|\lambda(d(x,y)) \\ &= \int_{E\times E} \|x-y\|\lambda(d(x,y)),\end{aligned}$$

so the proof is complete.

476L The Isoperimetric Theorem Let $r \geq 1$ be an integer, and let μ be Lebesgue measure on $\mathbb{R}^r$. If $E \subseteq \mathbb{R}^r$ is a measurable set of finite measure, then $\operatorname{per} E \geq \operatorname{per} B_E$, where B_E is the closed ball with centre $\mathbf{0}$ and the same measure as E, while $\operatorname{per} E$ is the perimeter of E as defined in 474D.

proof (a) Suppose to begin with that $E \subseteq B(\mathbf{0}, M)$, where $M \geq 0$, and that $\operatorname{per} E < \infty$. Let $\mathcal{F}$ be the family of measurable sets $F \subseteq \mathbb{R}^r$ such that $F \setminus B(\mathbf{0}, M)$ is negligible, $\mu F \geq \mu E$ and $\operatorname{per} F \leq \operatorname{per} E$, with the topology of convergence in measure (474S). Then

$$\begin{aligned}\mathcal{F} = \{F : \operatorname{per} F \leq \operatorname{per} E,\ &\mu(F \cap B(\mathbf{0}, M)) \geq \mu E, \\ &\mu(F \cap B(\mathbf{0},\alpha)) \leq \mu(F \cap B(\mathbf{0}, M)) \text{ for every } \alpha \geq 0\}\end{aligned}$$

is a closed subset of $\{F : \operatorname{per} F \leq \operatorname{per} E\}$, which is compact (474Sb), so $\mathcal{F}$ is compact. For $F \in \mathcal{F}$ set $h(F) = \int_F \|x\|\mu(dx)$; then $|h(F) - h(F')| \leq M\mu((F \triangle F') \cap B(\mathbf{0}, M))$ for all F, $F' \in \mathcal{F}$, so h is continuous.

There is therefore an $F_0 \in \mathcal{F}$ such that $h(F_0) \leq h(F)$ for every $F \in \mathcal{F}$. Set $F_1 = \text{cl}^*F_0$, so that $F_1 \triangle F_0$ is negligible (475Cg), $F_1 \in \mathcal{F}$, $F_1 \subseteq B(\mathbf{0}, M)$ and $h(F_1) = h(F_0)$.

(b) Writing $\delta = \sup_{x \in F_1} \|x\|$, we have $U(\mathbf{0}, \delta) \subseteq F_1$. **P?** Otherwise, there are $x_0 \in \mathbb{R}^r \setminus F_1$ and $x_1 \in F_1$ such that $\|x_0\| < \|x_1\|$. Set $e = \frac{1}{\|x_0 - x_1\|}(x_0 - x_1)$, $\alpha = \frac{1}{2} e \cdot (x_0 + x_1) < 0$, $R = R_{e\alpha} : \mathbb{R}^r \to \mathbb{R}^r$ and $\psi = \psi_{e\alpha}$. Set $F = \psi(F_1)$ and let $\phi = \phi_{F_1} : F_1 \to F$ be the function described in 476I. Then $\|\phi(x)\| \leq \|x\|$ for every $x \in F_1$ (476Ia). In particular, $F = \phi[F_1] \subseteq B(\mathbf{0}, M)$. Now F is measurable and $\mu F = \mu F_1 \geq \mu E$, by 476Ib. Also, writing ν for normalized $r-1$-dimensional Hausdorff measure on $\mathbb{R}^r$,

$$\text{per}\, F = \nu(\partial^* F) \leq \nu(\partial^* F_1) = \text{per}\, F_1 \leq \text{per}\, E,$$

by 475Mb and 476Ie. So $F \in \mathcal{F}$, and

$$\int_F \|x\| \mu(dx) \geq \int_{F_0} \|x\| \mu(dx) = \int_{F_1} \|x\| \mu(dx).$$

By 476Ic, $G = \{x : x \in F_1, x \cdot e < \alpha, R(x) \notin F_1\}$ is negligible. But now consider $G \cap U(x_1, \eta)$ for small $\eta > 0$. Since x_1 belongs to $F_1 = \text{cl}^*F_0 = \text{cl}^*F_1$, but x_0 does not,

$$\limsup_{\eta \downarrow 0} \frac{\mu(F_1 \cap B(x_1, \eta))}{\mu B(x_1, \eta)} > 0 = \limsup_{\eta \downarrow 0} \frac{\mu(F_1 \cap B(x_0, \eta))}{\mu B(x_0, \eta)}.$$

There must therefore be some $\eta > 0$ such that $\eta < \frac{1}{2}\|x_1 - x_0\|$ and $\mu(F_1 \cap B(x_0, \eta)) < \mu(F_1 \cap B(x_1, \eta))$. In this case, however, $G \supseteq F_1 \cap B(x_1, \eta) \setminus R[F_1 \cap B(x_0, \eta)]$ has measure at least $\mu(F_1 \cap B(x_1, \eta)) - \mu(F_1 \cap B(x_0, \eta)) > 0$, which is impossible. **XQ**

(c) Thus $U(\mathbf{0}, \delta) \subseteq F_1 \subseteq B(\mathbf{0}, \delta)$ and $\text{per}\, F_1 = \text{per}\, B(\mathbf{0}, \delta)$. Since $\mu F_1 \geq \mu E$, the radius of B_E is at most δ and

$$\text{per}\, B_E \leq \text{per}\, B(\mathbf{0}, \delta) = \text{per}\, F_1 \leq \text{per}\, E.$$

(d) Thus the result is proved when E is bounded and has finite perimeter. Of course it is trivial when E has infinite perimeter. Now suppose that E is any measurable set with finite measure and finite perimeter. Set $E_\alpha = E \cap B(\mathbf{0}, \alpha)$ for $\alpha \geq 0$; then $\text{per}\, E = \liminf_{\alpha \to \infty} \text{per}\, E_\alpha$ (475Mc). By (a)-(c), $\text{per}\, E_\alpha \geq \text{per}\, B_{E_\alpha}$; since $\text{per}\, B_{E_\alpha} \to \text{per}\, B_E$ as $\alpha \to \infty$, $\text{per}\, E \geq \text{per}\, B_E$ in this case also.

476M Spheres in inner product spaces For the rest of the section I will use the following notation. Let X be a (real) inner product space. Then S_X will be the unit sphere $\{x : x \in X, \|x\| = 1\}$. Let H_X be the isometry group of S_X with its topology of pointwise convergence (441G).

A **cap** in S_X will be a set of the form $\{x : x \in S_X, (x|e) \geq \alpha\}$ where $e \in S_X$ and $-1 \leq \alpha \leq 1$.

When X is finite-dimensional, it is isomorphic, as inner product space, to $\mathbb{R}^r$, where $r = \dim X$ (4A4Jd). In this case S_X is compact, so has a unique H_X-invariant Radon probability measure ν_X, which is strictly positive (476G). If $r \geq 1$ is an integer, we know that the $r-1$-dimensional Hausdorff measure of the sphere $S_{\mathbb{R}^r}$ is finite and non-zero (265F). Since Hausdorff measures are invariant under isometries (264G, 471J), and are quasi-Radon measures when totally finite (471Dh), $r-1$-dimensional Hausdorff measure on $S_{\mathbb{R}^r}$ is a multiple of the normalized invariant measure $\nu_{\mathbb{R}^r}$, by 476G. The same is therefore true in any r-dimensional inner product space.

476N Lemma Let X be a real inner product space and $f \in H_X$. Then $(f(x)|f(y)) = (x|y)$ for all x, $y \in S_X$. Consequently $f(\alpha x + \beta y) = \alpha f(x) + \beta f(y)$ whenever x, $y \in S_X$ and α, $\beta \in \mathbb{R}$ are such that $\alpha x + \beta y \in S_X$.

proof (a) We have

$$\rho(x, y)^2 = (x - y | x - y) = (x|x) - 2(x|y) + (y|y) = 2 - 2(x|y),$$

so

$$(x|y) = 1 - \tfrac{1}{2}\rho(x, y)^2 = 1 - \tfrac{1}{2}\rho(f(x), f(y))^2 = (f(x)|f(y)).$$

(b)

$$\begin{aligned}\|f(\alpha x+\beta y)-\alpha f(x)-\beta f(y)\|^2&\\ &=(f(\alpha x+\beta y)-\alpha f(x)-\beta f(y)|f(\alpha x+\beta y)-\alpha f(x)-\beta f(y))\\ &=1+\alpha^2+\beta^2-2\alpha(f(\alpha x+\beta y)|f(x))-2\beta(f(\alpha x+\beta y)|f(y))+2\alpha\beta(f(x)|f(y))\\ &=1+\alpha^2+\beta^2-2\alpha(\alpha x+\beta y|x)-2\beta(\alpha x+\beta y|y)+2\alpha\beta(x|y)\\ &=\|(\alpha x+\beta y)-\alpha x-\beta y\|^2=0.\end{aligned}$$

476O I give a theorem on concentration of measure on the sphere corresponding to 476J.

Theorem Let X be a finite-dimensional inner product space of dimension at least 2, S_X its unit sphere and ν_X the invariant Radon probability measure on S_X. For a non-empty set $A\subseteq S_X$ and $\epsilon>0$, write $U(A,\epsilon)=\{x:\rho(x,A)<\epsilon\}$, where ρ is the usual metric of X. Then there is a cap $C\subseteq S_X$ such that $\nu_X C=\nu_X^*A$, and $\nu_X(S_X\cap U(A,\epsilon))\geq\nu_X(S_X\cap U(C,\epsilon))$ for any such C.

proof In order to apply the results of 476H-476I directly, and simplify some of the formulae slightly, it will be helpful to write ν for the Radon measure on X defined by setting $\nu E=\nu_X(E\cap S_X)$ whenever this is defined. By 214Cd, ν^* agrees with ν_X^* on $\mathcal{P}S_X$.

(a) The first step is to check that there is a cap C of S_X such that $\nu C=\nu^*A$. **P** Take any $e_0\in S_X$, and set $C_\alpha=\{x:x\in S_X,\,(x|e_0)\geq\alpha\}$ for $\alpha\in[-1,1]$. νC_α is defined for every $\alpha\in\mathbb{R}$ because every C_α is closed and ν is a topological measure. Now examine the formulae of 265F. We can identify X with $\mathbb{R}^{r+1}$ where $r+1=\dim X$; do this in such a way that e_0 corresponds to the unit vector $(0,\dots,0,1)$. We have a parametrization $\phi_r:D_r\to S_X$, where D_r is a Borel subset of $\mathbb{R}^r$ with interior $]-\pi,\pi[\times]0,\pi[^{r-1}$ and ϕ_r is differentiable with continuous derivative. Moreover, if $x=(\xi_1,\dots,\xi_r)\in D_r$, then $\phi_r(x)\cdot e_0=\cos\xi_r$, and the Jacobian J_r of ϕ_r is bounded by 1 and never zero on $\operatorname{int}D_r$. Finally, the boundary ∂D_r is negligible. What this means is that $\nu_r C_\alpha=\int_{E_\alpha}J_r d\mu_r$, where μ_r is Lebesgue measure on $\mathbb{R}^r$, ν_r is normalized Hausdorff r-dimensional measure on $\mathbb{R}^{r+1}$, and $E_\alpha=\{x:x\in D_r,\cos\xi_r\geq\alpha\}$. So if $-1\leq\alpha\leq\beta\leq1$ then

$$\nu_r C_\alpha-\nu_r C_\beta\leq\mu_r(E_\alpha\setminus E_\beta)\leq 2\pi^{r-1}(\arccos\alpha-\arccos\beta);$$

because arccos is continuous, so is $\alpha\mapsto\nu_r C_\alpha$. Also, if $\alpha<\beta$, then $E_\alpha\setminus E_\beta$ is non-negligible, so $\int_{E_\alpha\setminus E_\beta}J_r d\mu_r\neq0$ and $\nu_r C_\alpha>\nu_r C_\beta$.

This shows that $\alpha\mapsto\nu_r C_\alpha$ is continuous and strictly decreasing; since ν_r is just a multiple of ν on S_X, the same is true of $\alpha\mapsto\nu C_\alpha$.

Since $\nu C_{-1}=\nu S_X=1$ and $\nu C_1=\nu\{e_0\}=0$, the Intermediate Value Theorem tells us that there is a unique α such that $\nu C_\alpha=\nu^*A$, and we can set $C=C_\alpha$. **Q**

(b) Now take any non-empty set $A\subseteq S_X$ and any $\epsilon>0$, and set $\gamma=\nu^*A$, $\beta=\nu U(A,\epsilon)$. Let C be a cap such that $\nu^*A=\nu C$; let e_0 be the centre of C. Consider the family

$$\mathcal{F}=\{F:F\in\mathcal{C}\setminus\{\emptyset\},\,F\subseteq S_X,\,\nu F\geq\gamma,\,\nu U(F,\epsilon)\leq\beta\},$$

where $\mathcal{C}$ is the family of closed subsets of X. Because $U(\overline{A},\epsilon)=U(A,\epsilon)$, $\overline{A}\in\mathcal{F}$ and $\mathcal{F}$ is non-empty. By 476D and 476F, $\mathcal{F}$ is closed for the Hausdorff metric on $\mathcal{C}\setminus\{\emptyset\}$, therefore compact, by 475Ad, because S_X is compact. Next, the function

$$F\mapsto\int_F\max(0,1+(x|e_0))\nu(dx):\mathcal{C}\setminus\{\emptyset\}\to[0,\infty[$$

is upper semi-continuous, by 476Dc. It therefore attains its supremum on $\mathcal{F}$ at some $F_0\in\mathcal{F}$. Let $F_1\subseteq F_0$ be a self-supporting closed set with the same measure as F_0; then $F_1\in\mathcal{F}$ and $\int_F(1+(x|e_0))\nu(dx)\geq\int_{F_1}(1+(x|e_0))\nu(dx)$ for every $F\in\mathcal{F}$.

(c) F_1 is a cap with centre e_0. **P?** Otherwise, there are $x_0\in S_X\setminus F_1$ and $x_1\in F_1$ such that $(x_0|e_0)>(x_1|e_0)$. Set $e=\frac{1}{\|x_0-x_1\|}(x_0-x_1)$. Then $e\in S_X$ and $(e|e_0)>0$. Set $R=R_{e0}$ and $\psi=\psi_{e0}$ as defined in 476H; write F for $\psi(F_1)$. Note that $(x_0+x_1|x_0-x_1)=\|x_0\|^2-\|x_1\|^2=0$, so $(x_0+x_1|e)=0$ and

$R(x_0) = x_1$. Also $R[S_X] = S_X$, so ν is R-invariant, because ν is a multiple of Hausdorff $r-1$-dimensional measure on S_X and must be invariant under isometries of S_X.

We have $\nu F = \nu F_1 \geq \gamma$, by 476Ib, and

$$\nu U(F,\epsilon) \leq \nu\psi(U(F_1,\epsilon)) = \nu U(F_1,\epsilon) \leq \nu U(F_0,\epsilon) \leq \beta$$

by 476Ha. So $F \in \mathcal{F}$. But consider the standard bijection $\phi = \phi_{F_1} : F_1 \to F$ as defined in 476I. We have

$$\int_{F_1}(1+(\phi(x)|e_0))\nu(dx) = \int_F (1+(x|e_0))\nu(dx) \leq \int_{F_1}(1+(x|e_0))\nu(dx).$$

But if we examine the definition of ϕ, we see that $\phi(x) \neq x$ only when $(x|e) < 0$ and $\phi(x) = R(x)$, so that in this case $\phi(x) - x$ is a positive multiple of e and $(\phi(x)|e_0) > (x|e_0)$. So $G = \{x : x \in F_1,\ (x|e) < 0,\ R(x) \notin F_1\}$ must be ν-negligible. But G includes a relative neighbourhood of x_1 in F_1 and F_1 is supposed to be self-supporting for ν, so this is impossible. **XQ**

(e) Now $\nu^* A = \gamma \leq \nu F_1$, so $C \subseteq F_1$ and

$$\nu U(A,\epsilon) = \beta \geq \nu U(F_1,\epsilon) \geq \nu U(C,\epsilon),$$

as claimed.

476P Corollary For any $\epsilon > 0$, there is an $r_0 \geq 2$ such that whenever X is a finite-dimensional inner product space of dimension at least r_0, A_1, $A_2 \subseteq S_X$ and $\min(\nu_X^* A_1, \nu_X^* A_2) \geq \epsilon$, then there are $x \in A_1$, $y \in A_2$ such that $\|x - y\| \leq \epsilon$.

proof Take $r_0 \geq 2$ such that $r_0\epsilon^3 > 2$. Suppose that $\dim X = r \geq r_0$. Fix $e_0 \in S_X$. We need an estimate of $\nu_X C_{\epsilon/2}$, where $C_{\epsilon/2} = \{x : x \in S_X,\ (x|e_0) \geq \epsilon/2\}$ as in 476O. To get this, let $e_1, \ldots, e_{r-1}$ be such that $e_0, \ldots, e_{r-1}$ is an orthonormal basis of X (4A4Kc). For each $i < r$, there is an $f \in H_X$ such that $f(e_i) = e_0$, so that $(x|e_i) = (f(x)|e_0)$ for every x (476N), and

$$\int (x|e_i)^2 \nu_X(dx) = \int (f(x)|e_0)^2 \nu_X(dx) = \int (x|e_0)^2 \nu_X(dx),$$

because $f : S_X \to S_X$ is inverse-measure-preserving for ν_X.

Accordingly

$$\begin{aligned}
\nu_X C_{\epsilon/2} &= \tfrac{1}{2}\nu_X\{x : x \in S_X,\ |(x|e_0)| \geq \epsilon/2\} \\
&\leq \frac{2}{\epsilon^2}\int_{S_X}(x|e_0)^2\nu_X(dx) < r\epsilon\int_{S_X}(x|e_0)^2\nu_X(dx) \\
&= \epsilon\sum_{i=0}^{r-1}\int_{S_X}(x|e_i)^2\nu_X(dx) = \epsilon\int_{S_X}\sum_{i=0}^{r-1}(x|e_i)^2\nu_X(dx) = \epsilon \leq \nu_X^* A_1.
\end{aligned}$$

So, taking C to be the cap of S_X with centre e_0 and measure $\nu^* A_1$, $C = C_\alpha$ where $\alpha < \frac{1}{2}\epsilon$, and

$$\nu_X(S_X \cap U(A_1, \tfrac{1}{2}\epsilon)) \geq \nu_X(S_X \cap U(C_\alpha, \tfrac{1}{2}\epsilon)) \geq \nu_X C_{\alpha - \epsilon/2} > \frac{1}{2}.$$

Similarly, $\nu_X(S_X \cap U(A_2, \frac{1}{2}\epsilon)) > \frac{1}{2}$ and there must be some $z \in S_X \cap U(A_1, \frac{1}{2}\epsilon) \cap U(A_2, \frac{1}{2}\epsilon)$. Take $x \in A_1$ and $y \in A_2$ such that $\|x - z\| < \frac{1}{2}\epsilon$ and $\|y - z\| < \frac{1}{2}\epsilon$; then $\|x - y\| \leq \epsilon$, as required.

476X Basic exercises (a) Let (X,ρ) be a metric space and give $\mathcal{C} \setminus \{\emptyset\}$ its Hausdorff metric, where $\mathcal{C}$ is the family of closed subsets of X. (i) Show that $x \mapsto \{x(i) : i < n\} : X^n \to \mathcal{C} \setminus \{\emptyset\}$ is continuous for every $n \geq 1$. (ii) Show that $(E,F) \mapsto E \cup F : (\mathcal{C} \setminus \{\emptyset\})^2 \to \mathcal{C} \setminus \{\emptyset\}$ is continuous. (iii) Show that $\operatorname{diam} : \mathcal{C} \setminus \{\emptyset\} \to [0,\infty]$ is continuous.

(b) Let (X,ρ) be a metric space and $\mathcal{K}$ the family of compact subsets of X. (i) Show that the Hausdorff metric topology and the Vietoris topology coincide on $\mathcal{K} \setminus \{\emptyset\}$. (ii) Show that if G is the isometry group of X with its topology of pointwise convergence (441G), then $(g,K) \mapsto g[K]$ is a continuous action of G on $\mathcal{K}$ if $\mathcal{K}$ is given the topology induced by the Vietoris topology.

(c) Let (X,ρ) be a metric space, and $\mathcal{C}$ the set of closed subsets of X. Show that the topology induced by the Hausdorff metric on $\mathcal{C}\setminus\{0\}$ is finer than the subspace topology induced by the k-Vietoris topology on $\mathcal{C}$.

(d) Let (X,ρ) be a locally compact metric space, and $\mathcal{C}$ the set of closed subsets of X with its k-Vietoris topology. (i) Show that if G is the isometry group of X with its topology of pointwise convergence, then $(g,C)\mapsto g[C]$ is a continuous action of G on $\mathcal{C}$. (ii) Show that if X is separable then $\mathcal{C}$ is metrizable.

(e) Let (X,ρ) be a metric space and give $\mathcal{C}\setminus\{\emptyset\}$ its Hausdorff metric, where $\mathcal{C}$ is the family of closed subsets of X. Show that whenever μ is a topological measure on X and f is a μ-integrable real-valued function, then $F\mapsto\int_F f\,d\mu:\mathcal{C}\setminus\{0\}\to\mathbb{R}$ is Borel measurable.

(f) Let X be a topological space and give $\mathcal{C}$ its Vietoris topology, where $\mathcal{C}$ is the family of closed subsets of X. (i) Show that if X is T_0 then $x\mapsto\{x(i):i<n\}:X^n\to\mathcal{C}\}$ is continuous for every $n\geq 1$. (ii) Show that $(E,F)\mapsto E\cup F:\mathcal{C}^2\to\mathcal{C}$ is continuous.

(g) In the context of 476H, show that $\operatorname{diam}\psi_{e\alpha}(A)\leq\operatorname{diam}A$ for all A, e and α.

>(h) Find an argument along the lines of those in 476J and 476K to prove 264H. (*Hint*: 476Xg.)

>(i) Let X be an inner product space and S_X its unit sphere. Show that every isometry $f:S_X\to S_X$ extends uniquely to an isometry $T_f:X\to X$ which is a linear operator. (*Hint*: first check the cases in which $\dim X\leq 2$.) Show that f is surjective iff T_f is, so that we have a natural isomorphism between the isometry group of S_X and the group of invertible isometric linear operators. Show that this isomorphism is a homeomorphism for the topologies of pointwise convergence.

(j) Let X be a finite-dimensional inner product space, ν_X the invariant Radon probability measure on the sphere S_X, and $E\in\operatorname{dom}\nu_X$; let $C\subseteq S_X$ be a cap with the same measure as E, and let λ be the product measure of ν_X with itself on $S_X\times S_X$. Show that $\int_{C\times C}\|x-y\|\lambda(d(x,y))\leq\int_{E\times E}\|x-y\|\lambda(d(x,y))$.

(k) Let X be a finite-dimensional inner product space and ν_X the invariant Radon probability measure on the sphere S_X. (i) Without appealing to the formulae in §265, show that $\nu_X(S_X\cap H)=0$ for whenever $H\subseteq X$ is a proper affine subspace. (*Hint*: induce on $\dim H$.) (ii) Use this to prove that if $e\in S_X$ then $\alpha\mapsto\nu_X\{x:(x|e)\geq\alpha\}$ is continuous.

476Y Further exercises (a) Let (X,ρ) and (Y,σ) be metric spaces, and $f:X\to Y$ a function. Write $\mathcal{C}_X$, $\mathcal{C}_Y$ for the spaces of closed subsets of X, Y respectively, and give $\mathcal{C}_X\setminus\{\emptyset\}$, $\mathcal{C}_Y\setminus\{\emptyset\}$ their Hausdorff metrics. For $F\in\mathcal{C}_X\setminus\{\emptyset\}$ set $\tilde{f}(F)=\overline{f[F]}\in\mathcal{C}_Y\setminus\{\emptyset\}$. Show that the following are equiveridical: (i) f is uniformly continuous (ii); $\tilde{f}$ is continuous; (iii) $\tilde{f}$ is uniformly continuous.

(b) Let X and Y be topological spaces, and $\mathcal{C}_X$, $\mathcal{C}_Y$ the spaces of closed subsets of X, Y respectively, with their Vietoris topologies. Suppose that $f:X\to Y$ is a continuous function and that Y is normal. Show that $F\mapsto\overline{f[F]}:\mathcal{C}_X\to\mathcal{C}_Y$ is continuous.

(c) Let X be a compact metric space and G its isometry group. Suppose that $H\subseteq G$ is a subgroup such that the action of H on X is transitive. Show that X has a unique H-invariant Radon probability measure which is also G-invariant.

476 Notes and comments The main theorems here (476J-476K, 476O), like 264H, are all 'classical'; they go back to the roots of geometric measure theory, and the contribution of the twentieth century has been to extend the classes of sets for which balls or caps provide the bounding examples. It is very striking that they can all be proved with the same tools (see 476Xh). Of course I should remark that the Compactness Theorem (474S) lies at a much deeper level than the rest of the ideas here. (The proof of 474S relies on the distributional definition of 'perimeter' in 474D, while the arguments of 476Ie and 476L work with the Hausdorff measures of essential boundaries; so that we can join these ideas together only after proving all the

principal theorems of §§472-475.) So while 'Steiner symmetrization' (264H) and 'concentration by partial reflection' (476H) are natural companions, 476L is essentially harder than the other results.

In all the theorems here, as in 264H, I have been content to show that a ball or a cap is an optimum for whatever inequality is being considered. I have not examined the question of whether, and in what sense, the optimum is unique. It seems that this requires deeper analysis.

Chapter 48

Gauge integrals

For the penultimate chapter of this volume I turn to a completely different approach to integration which has been developed in the last forty years, following KURZWEIL 57 and HENSTOCK 63. This depends for its inspiration on a particular formulation of the Riemann integral (see 481Xe), and leads in particular to some remarkable extensions of the Lebesgue integral (§§483-484). While (in my view) it remains peripheral to the most important parts of measure theory, it has deservedly attracted a good deal of interest in recent years, and is entitled to a place here.

From the very beginning, in the definitions of §122, I have presented the Lebesgue integral in terms of almost-everywhere approximations by simple functions. Because the integral $\int \lim_{n\to\infty} f_n$ of a limit is *not* always the limit $\lim_{n\to\infty} \int f_n$ of the integrals, we are forced, from the start, to constrain ourselves by the ordering, and to work with monotone or dominated sequences. This almost automatically leads us to an 'absolute' integral, in which $|f|$ is integrable whenever f is, whether we start from measures (as in Chapter 11) or from linear functionals (as in §436). For four volumes now I have been happily developing the concepts and intuitions appropriate to such integrals. But if we return to one of the foundation stones of Lebesgue's theory, the Fundamental Theorem of Calculus, we find that it is easy to construct a differentiable function f such that the absolute value $|f'|$ of its derivative is not integrable (483Xd). It was observed very early (PERRON 14) that the Lebesgue integral can be extended to integrate the derivative of any function which is differentiable everywhere. The achievement of HENSTOCK 63 was to find a formulation of this extension which was conceptually transparent enough to lend itself to a general theory, fragments of which I will present here.

The first step is to set out the essential structures on which the theory depends (§481), with a first attempt at a classification scheme. (One of the most interesting features of the Kurzweil-Henstock approach is that we have an extraordinary degree of freedom in describing our integrals, and apart from the Henstock integral itself it is not clear that we have yet found the right canonical forms to use.) In §482 I give a handful of general theorems showing what kind of results can be expected and what difficulties arise. In §483, I work through the principal properties of the Henstock integral on the real line, showing, in particular, that it coincides with the Perron and special Denjoy integrals. Finally, in §484, I look at a very striking integral on $\mathbb{R}^r$, due to W.F.Pfeffer.

481 Tagged partitions

I devote this section to establishing some terminology (481A-481B, 481E-481G) and describing a variety of examples (481I-481Q), some of which will be elaborated later. The clearest, simplest and most important example is surely Henstock's integral on a closed bounded interval (481J), so I recommend turning immediately to that paragraph and keeping it in mind while studying the notation here. It may also help you to make sense of the definitions here if you glance at the statements of some of the results in §482; in this section I give only the formula defining gauge integrals (481C), with some elementary examples of its use (481Xb-481Xh).

481A Tagged partitions and Riemann sums The common idea underlying all the constructions of this chapter is the following. We have a set X and a functional ν defined on some family $\mathcal{C}$ of subsets of X. We seek to define an integral $\int f d\nu$, for functions f with domain X, as a limit of *finite* **Riemann sums** $\sum_{i=0}^{n} f(x_i)\nu C_i$, where $x_i \in X$ and $C_i \in \mathcal{C}$ for $i \leq n$. There is no strict reason, at this stage, to forbid repetitions in the string $(x_0, C_0), \dots, (x_n, C_n)$, but also little to be gained from allowing them, and it will simplify some of the formulae below if I say from the outset that a **tagged partition** on X will be a finite subset $\boldsymbol{t}$ of $X \times \mathcal{P}X$.

So one necessary element of the definition will be a declaration of which tagged partitions $\{(x_0, C_0), \dots, (x_n, C_n)\}$ will be employed, in terms, for instance, of which sets C_i are permitted, whether they are allowed to overlap at their boundaries, whether they are required to cover the space, and whether each **tag** x_i is required to belong to the corresponding C_i. The next element of the definition will be a description of a filter $\mathcal{F}$ on the set T of tagged partitions, so that the integral will be the limit (when it exists) of the sums along the filter, as in 481C below.

In the formulations studied in this chapter, the C_i will generally be disjoint, but this is not absolutely essential, and it is occasionally convenient to allow them to overlap in 'small' sets, as in 481Ya. In some cases, we can restrict attention to families for which the C_i are non-empty and have union X, so that $\{C_0, \dots, C_n\}$ is a partition of X in the strict sense.

481B Notation Let me immediately introduce notations which will be in general use throughout the chapter.

(a) First, a shorthand to describe a particular class of sets of tagged partitions. If X is a set, a **straightforward set of tagged partitions** on X is a set of the form

$$T = \{\boldsymbol{t} : \boldsymbol{t} \in [Q]^{<\omega},\ C \cap C' = \emptyset \text{ whenever } (x, C), (x', C') \text{ are distinct members of } \boldsymbol{t}\}$$

where $Q \subseteq X \times \mathcal{P}X$; I will say that T is **generated** by Q. In this case, of course, Q can be recovered from T, since $Q = \bigcup T$. Note that no control is imposed on the tags at this point. It remains theoretically possible that a pair $(x, \emptyset)$ should belong to Q, though in essentially all applications this will be excluded in one way or another.

(b) If X is a set and $\boldsymbol{t} \subseteq X \times \mathcal{P}X$ is a tagged partition, I write

$$W_{\boldsymbol{t}} = \bigcup\{C : (x, C) \in \boldsymbol{t}\}.$$

(c) If X is a set, $\mathcal{C}$ is a family of subsets of X, $f : X \to \mathbb{R}$ and $\nu : \mathcal{C} \to \mathbb{R}$ are functions and $\boldsymbol{t} \in [X \times \mathcal{C}]^{<\omega}$ is a tagged partition, then

$$S_{\boldsymbol{t}}(f, \nu) = \textstyle\sum_{(x,C)\in\boldsymbol{t}} f(x)\nu C.$$

481C Proposition Let X be a set, $\mathcal{C}$ a family of subsets of X, $T \subseteq [X \times \mathcal{C}]^{<\omega}$ a non-empty set of tagged partitions and $\mathcal{F}$ a filter on T. For any functions $f : X \to \mathbb{R}$ and $\nu : \mathcal{C} \to \mathbb{R}$, set

$$I_\nu(f) = \lim_{\boldsymbol{t}\to\mathcal{F}} S_{\boldsymbol{t}}(f, \nu)$$

if this is defined in $\mathbb{R}$.

(a) I_ν is a linear functional defined on a linear subspace of $\mathbb{R}^X$.

(b) Now suppose that $\nu C \geq 0$ for every $C \in \mathcal{C}$. Then

(i) I_ν is a positive linear functional (definition: 351F);

(ii) if f, $g : X \to \mathbb{R}$ are such that $|f| \leq g$ and $I_\nu(g)$ is defined and equal to 0, then $I_\nu(f)$ is defined and equal to 0.

proof (a) We have only to observe that if f, $g \in \mathbb{R}^X$ and $\alpha \in \mathbb{R}$, then

$$S_{\boldsymbol{t}}(f + g, \nu) = S_{\boldsymbol{t}}(f, \nu) + S_{\boldsymbol{t}}(g, \nu), \quad S_{\boldsymbol{t}}(\alpha f, \nu) = \alpha S_{\boldsymbol{t}}(f, \nu)$$

for every $\boldsymbol{t} \in T$, and apply 2A3Sf.

(b) If $g \geq 0$ in $\mathbb{R}^X$, that is, $g(x) \geq 0$ for every $x \in X$, then $S_{\boldsymbol{t}}(g, \nu) \geq 0$ for every $\boldsymbol{t} \in T$, so the limit $I_\nu(g)$, if defined, will also be non-negative. Next, if $|f| \leq g$, then $|S_{\boldsymbol{t}}(f, \nu)| \leq S_{\boldsymbol{t}}(g, \nu)$ for every $\boldsymbol{t}$, so if $I_\nu(g) = 0$ then $I_\nu(f)$ is also zero.

481D Remarks (a) Functionals $I_\nu = \lim_{\boldsymbol{t}\to\mathcal{F}} S_{\boldsymbol{t}}(., \nu)$, as described above, are called **gauge integrals**.

(b) In fact even greater generality is possible at this point. There is no reason why f and ν should take real values. All we actually need is an interpretation of sums of products $f(x) \times \nu C$ in a space in which we can define limits. So for any linear spaces U, V and W with a bilinear functional $\phi : U \times V \to W$ (253A) and a Hausdorff linear space topology on W, we can set out to construct an integral of a function $f : X \to U$ with respect to a functional $\nu : \mathcal{C} \to V$ as a limit of sums $S_{\boldsymbol{t}}(f, \nu) = \sum_{(x,C)\in\boldsymbol{t}} \phi(f(x), \nu C)$ in W. I will not go farther along this path here. But it is worth noting that the constructions of this chapter lead the way to interesting vector integrals of many types.

(c) An extension which is, however, sometimes useful is to allow ν to be undefined (or take values outside $\mathbb{R}$, such as $\pm\infty$) on part of $\mathcal{C}$. In this case, set $\mathcal{C}_0 = \nu^{-1}[\mathbb{R}]$. Provided that $T \cap [X \times \mathcal{C}_0]^{<\omega}$ belongs to $\mathcal{F}$, we can still define I_ν, and 481C will still be true.

481E Gauges The most useful method (so far) of defining filters on sets of tagged partitions is the following. If X is a set, a **gauge** on X is a subset δ of $X \times \mathcal{P}X$. For a gauge δ, a tagged partition $\boldsymbol{t}$ is **δ-fine** if $\boldsymbol{t} \subseteq \delta$. Now, for a set Δ of gauges and a set T of tagged partitions, we can seek to define a filter $\mathcal{F}$ on T as the filter generated by sets of the form $T_\delta = \{\boldsymbol{t} : \boldsymbol{t} \in T \text{ is } \delta\text{-fine}\}$ as δ runs over Δ. Of course we shall need to establish that T and Δ are compatible in the sense that $\{T_\delta : \delta \in \Delta\}$ has the finite intersection property; this will ensure that there is indeed a filter containing every T_δ (4A1Ia).

In nearly all cases, Δ will be non-empty and downwards-directed (that is, for any δ_1, $\delta_2 \in \Delta$ there will be a $\delta \in \Delta$ such that $\delta \subseteq \delta_1 \cap \delta_2$); in this case, we shall need only to establish that T_δ is non-empty for every $\delta \in \Delta$. Note that the filter on T generated by $\{T_\delta : \delta \in \Delta\}$ depends only on T and the filter on $X \times \mathcal{P}X$ generated by Δ.

The most important gauges (so far) are 'neighbourhood gauges'. If $(X, \mathfrak{T})$ is a topological space, a **neighbourhood gauge** on X is a set expressible in the form $\delta = \{(x, C) : x \in X,\ C \subseteq G_x\}$ where $\langle G_x \rangle_{x \in X}$ is a family of open sets such that $x \in G_x$ for every $x \in X$. It is useful to note (i) that the family $\langle G_x \rangle_{x \in X}$ can be recovered from δ, since $G_x = \bigcup\{A : (x, A) \in \delta\}$ (ii) that $\delta_1 \cap \delta_2$ is a neighbourhood gauge whenever δ_1 and δ_2 are. When (X, ρ) is a metric space, we can define a neighbourhood gauge δ_h from any function $h : X \to]0, \infty[$, setting

$$\delta_h = \{(x, C) : x \in X,\ C \subseteq X,\ \rho(y, x) < h(x) \text{ for every } y \in C\}.$$

The set of gauges expressible in this form is coinitial with the set of all neighbourhood gauges and therefore defines the same filter on any compatible set T of tagged partitions. Specializing yet further, we can restrict attention to constant functions h, obtaining the **uniform metric gauges**

$$\delta_\eta = \{(x, C) : x \in X,\ C \subseteq X,\ \rho(x, y) < \eta \text{ for every } y \in C\}$$

for $\eta > 0$, used in the Riemann integral (481I). (The use of the symbol 'δ' to represent a gauge has descended from its traditional appearance in the definition of the Riemann integral.)

481F Residual sets The versatility and power of the methods being introduced here derives from the insistence on taking *finite* sums $\sum_{(x,C) \in \boldsymbol{t}} f(x)\nu C$, so that all questions about convergence are concentrated in the final limit $\lim_{\boldsymbol{t} \to \mathcal{F}} S_{\boldsymbol{t}}(f, \nu)$. Since in a given Riemann sum we can look at only finitely many sets C of finite measure, we cannot insist, even when ν is Lebesgue measure on $\mathbb{R}$, that $W_{\boldsymbol{t}}$ should always be X. There are many other cases in which it is impossible or inappropriate to insist that $W_{\boldsymbol{t}} = X$ for every tagged partition in T. We shall therefore need to add something to the definition of the filter $\mathcal{F}$ on T beyond what is possible in the language of 481E. In the examples below, the extra condition will always be of the following form. There will be a collection $\mathfrak{R}$ of **residual families** $\mathcal{R} \subseteq \mathcal{P}X$. It will help to have a phrase corresponding to the phrase 'δ-fine': if $\mathcal{R} \subseteq \mathcal{P}X$, and $\boldsymbol{t}$ is a tagged partition on X, I will say that $\boldsymbol{t}$ is **$\mathcal{R}$-filling** if $X \setminus W_{\boldsymbol{t}} \in \mathcal{R}$. Now, given a family $\mathfrak{R}$ of residual sets, and a family Δ of gauges on X, we can seek to define a filter $\mathcal{F}(T, \Delta, \mathfrak{R})$ on T as that generated by sets of the form

$$T_{\delta\mathcal{R}} = \{\boldsymbol{t} : \boldsymbol{t} \in T \text{ is } \delta\text{-fine and } \mathcal{R}\text{-filling}\}$$

where δ runs over Δ and $\mathcal{R}$ runs over $\mathfrak{R}$. When there is such a filter, that is, the family $\{T_{\delta R} : \delta \in \Delta,\ \mathcal{R} \in \mathfrak{R}\}$ has the finite intersection property, I will say that T is **compatible** with Δ and $\mathfrak{R}$.

It is important here to note that we shall *not* suppose that, for a typical residual family $\mathcal{R} \in \mathfrak{R}$, subsets of members of $\mathcal{R}$ again belong to $\mathcal{R}$; there will frequently be a restriction on the 'shape' of members of $\mathcal{R}$ as well as on their size. On the other hand, it will usually be helpful to arrange that $\mathfrak{R}$ is a filter base, so that (if Δ is also downwards-directed) we need only show that every $T_{\delta\mathcal{R}}$ is non-empty, and $\{T_{\delta\mathcal{R}} : \delta \in \Delta,\ \mathcal{R} \in \mathfrak{R}\}$ will be a base for $\mathcal{F}(T, \Delta, \mathfrak{R})$.

If the filter $\mathcal{F}$ is defined as in 481E, with no mention of a family $\mathfrak{R}$, we can still bring the construction into the framework considered here by setting $\mathfrak{R} = \{\mathcal{P}X\}$. If it is convenient to define T in terms which do not impose any requirement on the sets $W_{\boldsymbol{t}}$, but nevertheless we wish to restrict attention to sums $S_{\boldsymbol{t}}(f, \nu)$ for which the tagged partition covers the whole space X, we can do so by setting $\mathfrak{R} = \{\{\emptyset\}\}$.

481G Subdivisions When we come to analyse the properties of integrals constructed by the method of 481C, there is an important approach which depends on the following combination of features. I will say that $(X, T, \Delta, \mathfrak{R})$ is a **tagged-partition structure allowing subdivisions**, **witnessed by** $\mathcal{C}$, if

(i) X is a set.

(ii) Δ is a downwards-directed family of gauges on X.

(iii)(α) $\mathfrak{R}$ is a non-empty downwards-directed collection of families of subsets of X, all containing $\emptyset$;

(β) for every $\mathcal{R} \in \mathfrak{R}$ there is an $\mathcal{R}' \in \mathfrak{R}$ such that $A \cup B \in \mathcal{R}$ whenever A, $B \in \mathcal{R}'$ are disjoint.

(iv) $\mathcal{C}$ is a family of subsets of X such that whenever C, $C' \in \mathcal{C}$ then $C \cap C' \in \mathcal{C}$ and $C \setminus C'$ is expressible as the union of a disjoint finite subset of $\mathcal{C}$.

(v) Whenever $\mathcal{C}_0 \subseteq \mathcal{C}$ is finite and $\mathcal{R} \in \mathfrak{R}$, there is a finite set $\mathcal{C}_1 \subseteq \mathcal{C}$, including $\mathcal{C}_0$, such that $X \setminus \bigcup \mathcal{C}_1 \in \mathcal{R}$.

(vi) $T \subseteq [X \times \mathcal{C}]^{<\omega}$ is (in the language of 481Ba) a straightforward set of tagged partitions on X.

(vii) Whenever $C \in \mathcal{C}$, $\delta \in \Delta$ and $\mathcal{R} \in \mathfrak{R}$ there is a δ-fine tagged partition $\boldsymbol{t} \in T$ such that $W_{\boldsymbol{t}} \subseteq C$ and $C \setminus W_{\boldsymbol{t}} \in \mathcal{R}$.

481H Remarks(a) Conditions (ii) and (iii-α) of 481G are included primarily for convenience, since starting from any Δ and $\mathfrak{R}$ we can find directed sets leading to the same filter $\mathcal{F}(T, \Delta, \mathfrak{R})$. (iii-$\beta$), on the other hand, is saying something new.

(b) It is important to note, in (vii) of 481G, that the tags of $\boldsymbol{t}$ there are *not* required to belong to the set C.

(c) All the applications below will fall into one of two classes. In one type, the residual families $\mathcal{R} \in \mathfrak{R}$ will be families of 'small' sets, in some recognisably measure-theoretic sense, and, in particular, we shall have subsets of members of any $\mathcal{R}$ belonging to $\mathcal{R}$. In the other type, (vii) of 481G will be true because we can always find $\boldsymbol{t} \in T$ such that $W_{\boldsymbol{t}} = C$.

(d) The following elementary fact got left out of §136 and Chapter 31. Let $\mathfrak{A}$ be a Boolean algebra and $C \subseteq \mathfrak{A}$. Set

$$E = \{\sup C_0 : C_0 \subseteq C \text{ is finite and disjoint}\}.$$

If $c \cap c'$ and $c \setminus c'$ belong to E for all c, $c' \in C$, then E is a subring of $\mathfrak{A}$. **P** Write $\mathcal{D}$ for the family of finite disjoint subsets of C. (i) If C_0, $C_1 \in \mathcal{D}$, then for $c \in C_0$, $c' \in C_1$ there is a $D_{cc'} \in \mathcal{D}$ with supremum $c \cap c'$. Now $D = \sup_{c \in C_0, c' \in C_1} D_{cc'}$ belongs to $\mathcal{D}$ and has supremum $(\sup C_0) \cap (\sup C_1)$. Thus $e \cap e' \in E$ for all e, $e' \in E$. (ii) Of course $e \cup e' \in E$ whenever e, $e' \in E$ and $e \cap e' = 0$. (iii) Again suppose that C_0, $C_1 \in \mathcal{D}$. Then $c \setminus c' \in E$ for all $c \in C_0$, $c' \in C_1$. By (i), $c \setminus \sup C_1 \in E$ for every $c \in C$; by (ii), $(\sup C_0) \setminus (\sup C_1) \in E$. Thus $e \setminus e' \in E$ for all e, $e' \in E$. (iv) Putting (ii) and (iii) together, $e \triangle e' \in E$ for all e, $e' \in E$. (v) As $0 = \sup \emptyset$ belongs to E, E is a subring of $\mathfrak{A}$. **Q**

In particular, if $\mathcal{C} \subseteq \mathcal{P}X$ has the properties in (iv) of 481G, then

$$\mathcal{E} = \{\bigcup \mathcal{C}_0 : \mathcal{C}_0 \subseteq \mathcal{C} \text{ is finite and disjoint}\}$$

is a ring of subsets of X.

(e) Suppose that X is a set and that $\mathfrak{R} \subseteq \mathcal{P}\mathcal{P}X$ satisfies (iii) of 481G. Then for every $\mathcal{R} \in \mathfrak{R}$ there is a non-increasing sequence $\langle \mathcal{R}_n \rangle_{n \in \mathbb{N}}$ in $\mathfrak{R}$ such that $\bigcup_{i \le n} A_i \in \mathcal{R}$ whenever $A_i \in \mathcal{R}_i$ for $i \le n$ and $\langle A_i \rangle_{i \le n}$ is disjoint. **P** Take $\mathcal{R}_0 \in \mathfrak{R}$ such that $\mathcal{R}_0 \subseteq \mathcal{R}$ and $A \cup B \in \mathcal{R}$ for all disjoint A, $B \in \mathcal{R}_0$; similarly, for $n \in \mathbb{N}$, choose $\mathcal{R}_{n+1} \in \mathfrak{R}$ such that $\mathcal{R}_{n+1} \subseteq \mathcal{R}_n$ and $A \cup B \in \mathcal{R}_n$ for all disjoint A, $B \in \mathcal{R}_{n+1}$. Now, given that $A_i \in \mathcal{R}_i$ for $i \le n$ and $\langle A_i \rangle_{i \le n}$ is disjoint, we see by downwards induction on m that $\bigcup_{m < i \le n} A_i \in \mathcal{R}_m$ for each $m \le n$, so that $\bigcup_{i \le n} A_i \in \mathcal{R}$. **Q**

(f) If $(X, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions, then T is compatible with Δ and $\mathfrak{R}$ in the sense of 481F. **P** $\emptyset \in T$ so T is not empty. Take $\delta \in \Delta$ and $\mathcal{R} \in \mathfrak{R}$. Let $\langle \mathcal{R}_i \rangle_{i \in \mathbb{N}}$ be a sequence in $\mathfrak{R}$ such that $\bigcup_{i \le n} A_i \in \mathcal{R}$ whenever $A_i \in \mathcal{R}_i$ for $i \le n$ and $\langle A_i \rangle_{i \le n}$ is disjoint ((e) above). There is a

finite set $\mathcal{C}_1 \subseteq \mathcal{C}$ such that $X \setminus \bigcup \mathcal{C}_1 \in \mathcal{R}_0$, by 481G(iv). By (d), there is a disjoint family $\mathcal{C}_0 \subseteq \mathcal{C}$ such that $\bigcup \mathcal{C}_0 = \bigcup \mathcal{C}_1$; enumerate $\mathcal{C}_0$ as $\langle C_i \rangle_{i<n}$. For each $i < n$, there is a δ-fine $\boldsymbol{t}_i \in T$ such that $W_{\boldsymbol{t}_i} \subseteq C_i$ and $C_i \setminus W_{\boldsymbol{t}_i} \in \mathcal{R}_{i+1}$, by 481G(vii). Set $\boldsymbol{t} = \bigcup_{i<n} \boldsymbol{t}_i$; then $\boldsymbol{t} \in T$ is δ-fine, and

$$X \setminus W_{\boldsymbol{t}} = (X \setminus \bigcup \mathcal{C}_1) \cup \bigcup_{i<n} (C_i \setminus W_{\boldsymbol{t}_i}) \in \mathcal{R}$$

by the choice of $\langle \mathcal{R}_i \rangle_{i \in \mathbb{N}}$. Thus we have a δ-fine $\mathcal{R}$-filling member of T; as δ and $\mathcal{R}$ are arbitrary, T is compatible with Δ and $\mathfrak{R}$. **Q**

(g) For basic results which depend on 'subdivisions' as described in 481G(vii), see 482A-482B below. A different hypothesis asserting the existence of a sort of subdivision appears in 482G(iv).

481I I now run through some simple examples of these constructions, limiting myself for the moment to the definitions, the proofs that T is compatible with Δ and $\mathfrak{R}$, and (when appropriate) the proofs that the structures allow subdivisions.

The proper Riemann integral Fix a non-empty closed interval $X = [a, b] \subseteq \mathbb{R}$. Write $\mathcal{C}$ for the set of all non-empty intervals (open, closed or half-open) included in $[a, b]$, and set $Q = \{(x, C) : C \in C,\ x \in \overline{C}\}$; let T be the straightforward set of tagged partitions generated by Q. Let Δ be the set of uniform metric gauges on X, and $\mathfrak{R} = \{\{\emptyset\}\}$. Then $(X, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$.

proof (i), (iii) and (vi) of 481G are trivial and (ii), (iv) and (v) are elementary. As for (vii), given $\eta > 0$ and $C \in \mathcal{C}$, take a disjoint family $\langle C_i \rangle_{i \in I}$ of intervals of length less than 2η covering C, and x_i to be the midpoint of C_i for $i \in I$; then $\boldsymbol{t} = \{(x_i, C_i) : i \in I\}$ belongs to T and is δ_η-fine, in the language of 481E, and $W_{\boldsymbol{t}} = C$.

481J The Henstock integral on a bounded interval (HENSTOCK 63) Take X, $\mathcal{C}$, T and $\mathfrak{R}$ as in 481I. This time, let Δ be the set of *all* neighbourhood gauges on $[a, b]$. Then $(X, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$.

proof Again, only 481G(vii) needs more than a moment's consideration. Take any $C \in \mathcal{C}$. Set $a_0 = \inf C$, $b_0 = \sup C$ and let T_0 be the family of δ-fine partitions $\boldsymbol{t} \in T$ such that $W_{\boldsymbol{t}}$ is a relatively closed initial subinterval of C, that is, is of the form $C \cap [a_0, y_{\boldsymbol{t}}]$ for some $y_{\boldsymbol{t}} \in [a_0, b_0]$. Set $A = \{y_{\boldsymbol{t}} : \boldsymbol{t} \in T_0\}$. I have to show that there is a $\boldsymbol{t} \in T_0$ such that $W_{\boldsymbol{t}} = C$, that is, that $b_0 \in A$.

Observe that there is an $\eta_0 > 0$ such that $(a_0, A) \in \delta$ whenever $A \subseteq [a, b] \cap [a_0 - \eta_0, a_0 + \eta_0]$, and now $\{(a_0, [a_0, a_0 + \eta_0] \cap C)\}$ belongs to T_0, so $\min(a_0 + \eta_0, b_0) \in A$ and A is a non-empty subset of $[a_0, b_0]$. It follows that $c = \sup A$ is defined in $[a_0, b_0]$. Let $\eta > 0$ be such that $(c, A) \in \delta$ whenever $A \subseteq [a, b] \cap [c - \eta, c + \eta]$. There is some $\boldsymbol{t} \in T_0$ such that $y_{\boldsymbol{t}} \geq c - \eta$. If $y_{\boldsymbol{t}} = b_0$, we can stop. Otherwise, set $C' = C \cap]y_{\boldsymbol{t}}, c + \eta]$. Then $(c, C') \in \delta$ and $c \in \overline{C'}$ and $C' \cap W_{\boldsymbol{t}}$ is empty, so $\boldsymbol{t}' = \boldsymbol{t} \cup \{(c, C')\}$ belongs to T_0 and $y_{\boldsymbol{t}'} = \min(c + \eta, b_0)$. Since $y_{\boldsymbol{t}'} \leq c$, this shows that $y_{\boldsymbol{t}'} = c = b_0$ and again $b_0 \in A$, as required.

481K The Henstock integral on $\mathbb{R}$ This time, set $X = \mathbb{R}$ and let $\mathcal{C}$ be the family of all non-empty intervals in $\mathbb{R}$. Let T be the straightforward set of tagged partitions generated by $\{(x, C) : C \in \mathcal{C},\ x \in \overline{C}\}$. Following 481J, let Δ be the set of all neighbourhood gauges on $\mathbb{R}$. This time, set $\mathfrak{R} = \{\mathcal{R}_{ab} : a \leq b \in \mathbb{R}\}$, where $\mathcal{R}_{ab} = \{\mathbb{R} \setminus [c, d] : c \leq a,\ d \geq b\} \cup \{\emptyset\}$. Then $(X, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$.

proof This time we should perhaps take a moment to look at (iii) of 481G. But all we need to note is that $\mathcal{R}_{ab} \cap \mathcal{R}_{a'b'} = \mathcal{R}_{\min(a,a'),\max(b,b')}$, and that any two members of $\mathcal{R}_{ab}$ have non-empty intersection. Conditions (i), (ii), (iv), (v) and (vi) of 481G are again elementary, so once more we are left with (vii). But this can be dealt with by exactly the same argument as in 481J.

481L The symmetric Riemann-complete integral (cf. CARRINGTON 72, chap. 3) Again take $X = \mathbb{R}$, and $\mathcal{C}$ the set of all non-empty bounded intervals of X. This time, take T to be the straightforward set of tagged partitions generated by the set of pairs (x, C) where $C \in \mathcal{C}$ and x is the *midpoint* of C. As in

481K, take Δ to be the set of all neighbourhood gauges on $\mathbb{R}$; but this time take $\mathfrak{R} = \{\mathcal{R}'_a : a \geq 0\}$, where $\mathcal{R}'_a = \{\mathbb{R} \setminus [-c, c] : c \geq a\} \cup \{\emptyset\}$. Then T is compatible with Δ and $\mathfrak{R}$.

proof Take $\delta \in \Delta$ and $\mathcal{R} \in \mathfrak{R}$. For $x \geq 0$, let $\theta(x) > 0$ be such that $(x, D) \in \delta$ whenever $D \subseteq [x - \theta(x), x + \theta(x)]$ and $(-x, D) \in \delta$ whenever $D \subseteq [-x - \theta(x), -x + \theta(x)]$. Write A for the set of those $a > 0$ such that there is a finite sequence $a_0, \ldots, a_n$ such that $0 < a_0 < a_1 < \ldots < a_n = a$, $a_0 \leq \theta(0)$ and $a_{i+1} - a_i \leq 2\theta(\frac{1}{2}(a_i + a_{i+1}))$ for $i < n$.

? Suppose, if possible, that A is bounded above. Then $c = \inf([0, \infty[\setminus \overline{A})$ is defined in $[0, \infty[$. Observe that if $0 < a \leq \theta(0)$, then the one-term sequence a witnesses that $a \in A$. So $c \geq \theta(0) > 0$. Now there must be u, v such that $c < u < v < \min(c + \theta(c), 2c)$ and $]u, v[\cap A = \emptyset$; on the other hand, the interval $]2c - v, 2c - u[$ must contain a point x of A. Set $y = 2c - x$. Then we can find $a_0 < \ldots < a_n = x$ such that $0 < a_0 \leq \theta(0)$ and $a_{i+1} - a_i \leq 2\theta(\frac{1}{2}(a_i + a_{i+1}))$ for $i < n$; setting $a_{n+1} = y$, we see that $\langle a_i \rangle_{i \leq n+1}$ witnesses that $y \in A$, though $y \in]u, v[$. **X**

This contradiction shows that A is unbounded above. So now suppose that $\mathcal{R} = \mathcal{R}_a$ where $a \geq 0$. Take $a_0, \ldots, a_n$ such that $0 < a_0 < \ldots < a_n$, $0 < a_0 \leq \theta(0)$ and $a_{i+1} - a_i \leq 2\theta(\frac{1}{2}(a_i + a_{i+1}))$ for $i < n$, and $a_n \geq a$. For $i < n$, set $x_i = \frac{1}{2}(a_i + a_{i+1})$, $C_i =]a_i, a_{i+1}]$, $x'_i = -x_i$, $C'_i = [-a_{i+1}, a_i[$. Then x_i, x'_i are the midpoints of C_i, C'_i and (by the choice of the function θ) $(x_i, C_i) \in \delta$, $(x'_i, C'_i) \in \delta$ for $i < n$. So if we set

$$\boldsymbol{t} = \{(x_i, C_i) : i < n\} \cup \{(x'_i, C'_i) : i < n\} \cup \{(0, [-a_0, a_0])\}$$

we shall obtain a δ-fine $\mathcal{R}$-filling member of T.

As Δ and $\mathfrak{R}$ are both downwards-directed, this is enough to show that T is compatible with Δ and $\mathfrak{R}$.

481M The McShane integral on an interval (McShane 73) As in 481J, take $X = [a, b]$ and let $\mathcal{C}$ be the family of non-empty subintervals of $[a, b]$. This time, take T to be the straightforward set of tagged partitions generated by $Q = X \times \mathcal{C}$, so that *no* condition is imposed relating the tags to their associated intervals. As in 481J, let Δ be the set of all neighbourhood gauges on X, and $\mathfrak{R} = \{\{\emptyset\}\}$. Proceed as before. Since the only change is that Q and T have been enlarged, $(X, T, \Delta, \mathfrak{R})$ is still a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$.

481N The McShane integral on a topological space (Fremlin 95) Now let $(X, \mathfrak{T}, \Sigma, \mu)$ be any effectively locally finite τ-additive topological measure space, and take $\mathcal{C} = \{E : E \in \Sigma, \mu E < \infty\}$, $Q = X \times \mathcal{C}$; let T be the straightforward set of tagged partitions generated by Q. Again let Δ be the set of all neighbourhood gauges on X. This time, define $\mathfrak{R}$ as follows. For any set $E \in \Sigma$ of finite measure and $\eta > 0$, let $\mathcal{R}_{E\eta}$ be the set $\{F : F \in \Sigma, \mu(F \cap E) \leq \eta\}$, and set $\mathfrak{R} = \{\mathcal{R}_{E\eta} : \mu E < \infty, \eta > 0\}$. Then $(X, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$.

proof As usual, everything is elementary except perhaps 481G(vii). But if $C \in \mathcal{C}$, $\delta \in \Delta$, $E \in \Sigma$, $\mu E < \infty$ and $\eta > 0$, take for each $x \in X$ an open set G_x containing x such that $(x, A) \in \delta$ whenever $A \subseteq G_x$. $\{G_x : x \in X\}$ is an open cover of X, so by 414Ea there is a finite family $\langle x_i \rangle_{i<n}$ in X such that $\mu(E \cap C \setminus \bigcup_{i<n} G_{x_i}) \leq \eta$; setting $C_i = C \cap G_{x_i} \setminus \bigcup_{j<i} G_{x_j}$ for $i < n$, we get a δ-fine tagged partition $\boldsymbol{t} = \{(x_i, C_i) : i < n\}$ such that $C \setminus W_{\boldsymbol{t}} \in \mathcal{R}_{E\eta}$.

481O Convex partitions in $\mathbb{R}^r$ Fix $r \geq 1$. Let us say that a **convex polytope** in $\mathbb{R}^r$ is a non-empty bounded set expressible as the intersection of finitely many open or closed half-spaces; let $\mathcal{C}$ be the family of convex polytopes in $X = \mathbb{R}^r$, and T the straightforward set of tagged partitions generated by $\{(x, C) : x \in \overline{C}\}$. Let Δ be the set of neighbourhood gauges on $\mathbb{R}^r$. For $a \geq 0$, let $\mathcal{C}_a$ be the set of closed convex polytopes $C \subseteq \mathbb{R}^r$ such that, for some $b \geq a$, $B(0, b) \subseteq C \subseteq B(0, 2b)$, where $B(0, b)$ is the ordinary Euclidean ball with centre 0 and radius b; set $\mathcal{R}_a = \{\mathbb{R}^r \setminus C : C \in \mathcal{C}_a\} \cup \{\emptyset\}$, and $\mathfrak{R} = \{\mathcal{R}_a : a \geq 0\}$. Then $(X, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$.

proof As usual, only 481G(vii) requires thought.

(a) We need a geometrical fact: if $C \in \mathcal{C}$, $x \in \overline{C}$ and $y \in C$, then $\alpha y + (1 - \alpha)x \in C$ for every $\alpha \in]0, 1]$. **P** The family of sets $C \subseteq \mathbb{R}^r$ with this property is closed under finite intersections and contains all half-spaces. **Q** It follows that if C_1, $C_2 \in \mathcal{C}$ are not disjoint, then $\overline{C_1 \cap C_2} = \overline{C}_1 \cap \overline{C}_2$.

(b) Write $\mathcal{D} \subseteq \mathcal{C}$ for the family of products of non-empty bounded intervals in $\mathbb{R}$. The next step is to show that if $D \in \mathcal{D}$ and $\delta \in \Delta$, then there is a δ-fine tagged partition $\boldsymbol{t} \in T$ such that $W_{\boldsymbol{t}} = D$ and $\boldsymbol{t} \subseteq \mathbb{R}^r \times \mathcal{D}$. **P** Induce on r. For $r = 1$ this is just 481J again. For the inductive step to $r+1$, suppose that $D \subseteq \mathbb{R}^{r+1}$ is a product of bounded intervals and that δ is a neighbourhood gauge on $\mathbb{R}^{r+1}$. Identifying $\mathbb{R}^{r+1}$ with $\mathbb{R}^r \times \mathbb{R}$, express D as $D' \times L$, where $D' \subseteq \mathbb{R}^r$ is a product of bounded intervals and $L \subseteq \mathbb{R}$ is a bounded interval. For $y \in \mathbb{R}^r$, $\alpha \in \mathbb{R}$ let $G(y,\alpha)$, $H(y,\alpha)$ be open sets containing y, α respectively such that $((y,\alpha), A) \in \delta$ whenever $A \subseteq G(y,\alpha) \times H(y,\alpha)$. For $y \in \mathbb{R}^r$, set $\delta_y = \{(\alpha, A) : \alpha \in \mathbb{R}, A \subseteq H(y,\alpha)\}$; then δ_y is a neighbourhood gauge on $\mathbb{R}$.

By the one-dimensional case there is a δ_y-fine tagged partition $\boldsymbol{s}_y \in T_1$ such that $W_{\boldsymbol{s}_y} = L$, where I write T_1 for the set of tagged partitions used in 481K. Set

$$\delta' = \{(y, A) : y \in \mathbb{R}^r, A \subseteq G(y,\alpha) \text{ for every } (\alpha, F) \in \boldsymbol{s}_y\}.$$

δ' is a neighbourhood gauge on $\mathbb{R}^r$. By the inductive hypothesis, there is a δ'-fine tagged partition $\boldsymbol{u} \in T_r$ such that $W_{\boldsymbol{u}} = D'$, where here T_r is the set of tagged partitions on $\mathbb{R}^r$ corresponding to the r-dimensional version of this result. Consider the family

$$\boldsymbol{t} = \{((y,\alpha), E \times F) : (y, E) \in \boldsymbol{u}, (\alpha, F) \in \boldsymbol{s}_y\}.$$

For $(y, E) \in \boldsymbol{u}$, $(\alpha, F) \in \boldsymbol{s}_y$, we have

$$y \in \overline{E}, \quad E \subseteq G(y,\alpha), \quad \alpha \in \overline{F}, \quad F \subseteq H(y,\alpha),$$

so

$$(y,\alpha) \in \overline{E \times F}, \quad E \times F \subseteq G(y,\alpha) \times H(y,\alpha),$$

and $((y,\alpha), E \times F) \in \delta$. If $((y,\alpha), E \times F)$, $((y',\alpha'), E' \times F')$ are distinct members of $\boldsymbol{t}$, then either $(y, E) \neq (y', E')$ so $E \cap E' = \emptyset$ and $(E \times F) \cap (E' \times F')$ is empty, or $y = y'$ and (α, F), (α', F') are distinct members of $\boldsymbol{s}_y$, so that $F \cap F' = \emptyset$ and again $E \times F$, $E' \times F'$ are disjoint. Thus $\boldsymbol{t}$ is a δ-fine member of T_{r+1}. Finally,

$$W_{\boldsymbol{t}} = \bigcup_{(y,E) \in \boldsymbol{u}} \bigcup_{(\alpha,F) \in \boldsymbol{s}_y} E \times F = \bigcup_{(y,E) \in \boldsymbol{u}} E \times L = D' \times L = D.$$

So the induction proceeds. **Q**

(c) Now suppose that C_0 is an arbitrary member of $\mathcal{C}$ and that δ is a neighbourhood gauge on $\mathbb{R}^r$. Set

$$\delta' = \delta \cap \{(x, A) : \text{either } x \in \overline{C}_0 \text{ or } A \cap \overline{C}_0 = \emptyset\}.$$

Then δ' is a neighbourhood gauge on $\mathbb{R}^r$, being the intersection of δ with the neighbourhood gauge associated with the family $\langle U_x \rangle_{x \in \mathbb{R}^r}$, where $U_x = \mathbb{R}^r$ if $x \in \overline{C}_0$, $\mathbb{R}^r \setminus \overline{C}_0$ otherwise. Let $D \in \mathcal{D}$ be such that $C_0 \subseteq D$. By (b), there is a δ'-fine tagged partition $\boldsymbol{t} \in T$ such that $W_{\boldsymbol{t}} = D$. Set $\boldsymbol{s} = \{(x, C \cap C_0) : (x, C) \in \boldsymbol{t}, C \cap C_0 \neq \emptyset\}$. Since $\boldsymbol{t} \subseteq \delta'$, $x \in \overline{C}_0$ whenever $(x, C) \in \boldsymbol{t}$ and $C \cap C_0 \neq \emptyset$. By (a), $x \in \overline{C \cap C_0}$ for all such pairs (x, C); and of course $(x, C \cap C_0) \in \delta$ for every $(x, C) \in \boldsymbol{t}$. So $\boldsymbol{s}$ belongs to T, and $W_{\boldsymbol{s}} = W_{\boldsymbol{t}} \cap C_0 = C_0$. As C_0 and δ are arbitrary, 481G(vii) is satisfied.

481P Box products (cf. Muldowney 87, Prop. 1) Let $\langle (X_i, \mathfrak{T}_i) \rangle_{i \in I}$ be a non-empty family of non-empty compact metrizable spaces with product $(X, \mathfrak{T})$. Set $\pi_i(x) = x(i)$ for $x \in X$, $i \in I$. For each $i \in I$, let $\mathcal{C}_i \subseteq \mathcal{P}X_i$ be such that (α) whenever E, $E' \in \mathcal{C}_i$ then $E \cap E' \in \mathcal{C}_i$ and $E \setminus E'$ is expressible as the union of a disjoint finite subset of $\mathcal{C}_i$ (β) $\mathcal{C}_i$ includes a base for $\mathfrak{T}_i$.

Let $\mathcal{C}$ be the set of subsets of X of the form

$$C = \{X \cap \textstyle\bigcap_{i \in J} \pi_i^{-1}[E_i] : J \in [I]^{<\omega}, E_i \in \mathcal{C}_i \text{ for every } i \in J\},$$

and let T be the straightforward set of tagged partitions generated by $\{(x, C) : C \in \mathcal{C}, x \in \overline{C}\}$. Let Δ be the set of those neighbourhood gauges δ on X defined by families $\langle G_x \rangle_{x \in X}$ of open sets such that, for some countable $J \subseteq I$, every G_x is determined by coordinates in J (definition: 254M). Then $(X, T, \Delta, \{\{\emptyset\}\})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$.

proof Conditions (i), (iii) and (vi) of 481G are trivial, and (ii), (iv) and (v) are elementary; so we are left with (vii), as usual. **?** Suppose, if possible, that $C \in \mathcal{C}$ and $\delta \in \Delta$ are such that there is no δ-fine $\boldsymbol{t} \in T$ with $W_{\boldsymbol{t}} = C$. Let $\langle G_x \rangle_{x \in X}$ be the family of open sets determining δ, and $J \subseteq I$ a non-empty countable set

such that G_x is determined by coordinates in J for every $x \in X$. For $i \in J$, let $\mathcal{C}'_i \subseteq \mathcal{C}_i$ be a countable base for $\mathfrak{T}_i$ (4A2P(a-iii)), and take a sequence $\langle (i_n, E_n)\rangle_{n\in\mathbb{N}}$ running over $\{(i,E) : i \in J,\ E \in \mathcal{C}'_i\}$.

Write $\mathcal{D} = \{W_{\boldsymbol{t}} : \boldsymbol{t} \in T \text{ is } \delta\text{-fine}\}$. Note that if D_1, $D_2 \in \mathcal{D}$ are disjoint then $D_1 \cup D_2 \in \mathcal{D}$. So if $D \in \mathcal{C}\setminus\mathcal{D}$ and $C \in \mathcal{C}$, there must be some $D' \in \mathcal{C}\setminus\mathcal{D}$ such that either $D' \subseteq D \cap C$ or $D' \subseteq D \setminus C$, just because $\mathcal{C}$ satisfies 481G(iv). Now choose $\langle C_n\rangle_{n\in\mathbb{N}}$ inductively so that $C_0 = C$ and

$$C_n \in \mathcal{C}\setminus\mathcal{D},$$

$$\text{either } C_{n+1} \subseteq C_n \cap \pi_{i_n}^{-1}[E_n] \text{ or } C_{n+1} \subseteq C_n \setminus \pi_{i_n}^{-1}[E_n]$$

for every $n \in \mathbb{N}$. Because X, being a product of compact spaces, is compact, there is an $x \in \bigcap_{n\in\mathbb{N}} \overline{C_n}$. We know that G_x is determined by coordinates in J, so $G_x = \tilde{\pi}^{-1}[\tilde{\pi}[G_x]]$, where $\tilde{\pi}$ is the canonical map from X onto $Y = \prod_{i\in J} X_i$. $V = \tilde{\pi}[G_x]$ is open, so there must be a finite set $K \subseteq J$ and a family $\langle V_i\rangle_{i\in K}$ such that $x(i) \in V_i \in \mathfrak{T}_i$ for every $i \in K$ and $\{y : y \in Y,\ y(i) \in V_i \text{ for every } i \in K\}$ is included in V. This means that $\{z : z \in X,\ z(i) \subseteq V_i \text{ for every } i \in K\}$ is included in G_x. Now, for each $i \in K$, there is some $m \in \mathbb{N}$ such that $i = i_m$ and $x(i) \in E_m \subseteq V_i$. Because $x \in \overline{C}_{m+1}$, $\pi_{i_m}^{-1}[E_m]$ cannot be disjoint from C_{m+1}, and $C_{m+1} \subseteq \pi_{i_m}^{-1}[E_m] \subseteq \pi_i^{-1}[V_i]$.

But this means that, for any n large enough, $C_n \subseteq G_x$ and $\boldsymbol{t} = \{(x, C_n)\}$ is a δ-fine member of T with $W_{\boldsymbol{t}} = C_n$; contradicting the requirement that $C_n \notin \mathcal{D}$. **X**

This contradiction shows that 481G(vii) is also satisfied.

481Q The approximately continuous Henstock integral (Gordon 94, chap. 16) Let μ be Lebesgue measure on $\mathbb{R}$. As in 481K, let $\mathcal{C}$ be the family of non-empty bounded intervals in $\mathbb{R}$, and Q the set of pairs (x, C) where $C \in \mathcal{C}$ and $x \in \overline{C}$; let T be the straightforward set of tagged partitions defined from Q; and set $\mathfrak{R} = \{\mathcal{R}_{ab} : a,\ b \in \mathbb{R}\}$, where $\mathcal{R}_{ab} = \{\mathbb{R}\setminus[c,d] : c \le a,\ d \ge b\} \cup \{\emptyset\}$ for a, $b \in \mathbb{R}$.

This time, define gauges as follows. Let E be the set of families $\boldsymbol{e} = \langle E_x\rangle_{x\in\mathbb{R}}$ where every E_x is a measurable set containing x such that x is a density point of E_x (definition: 223B). For $\boldsymbol{e} = \langle E_x\rangle_{x\in\mathbb{R}} \in \mathrm{E}$, set

$$\delta_{\boldsymbol{e}} = \{(x,C) : C \in \mathcal{C},\ x \in \overline{C},\ \inf C \in E_x \text{ and } \sup C \in E_x\}.$$

Set $\Delta = \{\delta_{\boldsymbol{e}} : \boldsymbol{e} \in \mathrm{E}\}$. Then $(X, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$.

proof (a) Turning to 481G, we find, as usual, that most of the conditions are satisfied for elementary reasons. Since we have here a new kind of gauge, we had better check 481G(ii); but if $\boldsymbol{e} = \langle E_x\rangle_{x\in\mathbb{R}}$ and $\boldsymbol{e}' = \langle E'_x\rangle_{x\in\mathbb{R}}$ both belong to E, so does $\boldsymbol{e}\wedge\boldsymbol{e}' = \langle E_x \cap E'_x\rangle_{x\in\mathbb{R}}$, because

$$\begin{aligned}\liminf_{\eta\downarrow 0} \frac{1}{2\eta}\mu([x-\eta, x+\eta] \cap E_x \cap E'_x)&\\ \ge \lim_{\eta\downarrow 0} \frac{1}{2\eta}\big(\mu([x-\eta,x+\eta]\cap E_x) &+ \mu([x-\eta,x+\eta]\cap E'_x) - 2\eta\big) = 1\end{aligned}$$

for every x; and now $\delta_{\boldsymbol{e}} \cap \delta_{\boldsymbol{e}'} = \delta_{\boldsymbol{e}\wedge\boldsymbol{e}'}$ belongs to Δ. Everything else we have done before, except, of course, (vii).

(b) So take any $\delta \in \Delta$; express δ as $\delta_{\boldsymbol{e}}$, where $\boldsymbol{e} = \langle E_x\rangle_{x\in\mathbb{R}} \in \mathrm{E}$. For x, $y \in \mathbb{R}$, write $x \frown y$ if $x \le y$ and $E_x \cap E_y \cap [x,y] \ne \emptyset$; note that we always have $x \frown x$. For $x \in \mathbb{R}$, let $\eta_x > 0$ be such that $\mu(E_x \cap [x-\eta, x+\eta]) \ge \frac{5}{3}\eta$ whenever $0 \le \eta \le \eta_x$.

Fix $a < b$ in $\mathbb{R}$ for the moment. Say that a finite string $(x_0, \dots, x_n)$ is 'acceptable' if $a \le x_0 \frown \dots \frown x_n \le b$ and $\mu([x_0, x_n] \cap \bigcup_{i<n} E^+_{x_i}) \ge \frac{1}{2}(x_n - x_0)$, where $E^+_x = E_x \cap [x, \infty[$ for $x \in \mathbb{R}$. Observe that if $(x_0, \dots, x_m)$ and $(x_m, x_{m+1}, \dots, x_n)$ are both acceptable, so is $(x_0, \dots, x_n)$. For $x \in [a,b]$, set

$$h(x) = \sup\{x_n : (x, x_1, \dots, x_n) \text{ is acceptable}\};$$

this is defined in $[x,b]$ because the string (x) is acceptable. If $a \le x < b$, then (x,y) is acceptable whenever $y \in E_x$ and $0 \le y \le \min(b, x+\eta_x)$, so $h(x) > x$. Now choose sequences $\langle x_i\rangle_{i\in\mathbb{N}}$, $\langle n_k\rangle_{k\in\mathbb{N}}$ inductively, as follows. $n_0 = 0$ and $x_0 = a$. Given that $x_i \frown x_{i+1}$ for $i < n_k$ and that $(x_{n_j}, \dots, x_{n_k})$ is acceptable for

every $j \leq k$, let $n_{k+1} > n_k$, $(x_{n_k+1}, \ldots, x_{n_{k+1}})$ be such that $(x_{n_k}, \ldots, x_{n_{k+1}})$ is acceptable and $x_{n_{k+1}} \geq \frac{1}{2}(x_{n_k} + h(x_{n_k}))$; then $(x_{n_j}, \ldots, x_{n_{k+1}})$ is acceptable for any $j \leq k+1$; continue.

At the end of the induction, set

$$c = \sup_{i \in \mathbb{N}} x_i = \sup_{k \in \mathbb{N}} x_{n_k}.$$

Then there are infinitely many i such that $x_i \frown c$. **P** For any $k \in \mathbb{N}$,

$$\begin{aligned}\mu([x_{n_k}, c] \cap \bigcup_{i \geq n_k} E^+_{x_i}) &= \lim_{l \to \infty} \mu\big([x_{n_k}, x_{n_l}] \cap \bigcup_{n_k \leq i < n_l} E^+_{x_i}\big) \\ &\geq \lim_{l \to \infty} \frac{1}{2}(x_{n_l} - x_{n_k})\end{aligned}$$

(because $(x_{n_k}, \ldots, x_{n_l})$ is always an acceptable string)

$$= \frac{1}{2}(c - x_{n_k}).$$

But this means that if we take k so large that $x_{n_k} \geq c - \eta_c$, so that $\mu(E_c \cap [x_{n_k}, c]) \geq \frac{2}{3}(c - x_{n_k})$, there must be some $z \in E_c \cap \bigcup_{i \geq n_k} E^+_i \cap [x_{n_k}, c]$; and if $i \geq n_k$ is such that $z \in E^+_i$, then z witnesses that $x_i \frown c$. As k is arbitrarily large, we have the result. **Q**

? If $c < b$, take any $y \in E_c$ such that $c < y \leq \min(c + \eta_c, b)$. Take $k \in \mathbb{N}$ such that $x_{n_k} \geq c - \frac{1}{3}(y - c)$, and $j \geq n_k$ such that $x_j \frown c$. In this case, $(x_{n_k}, x_{n_k+1}, \ldots, x_j, c, y)$ is an acceptable string, because

$$\mu E^+_c \cap [x_{n_k}, y] \geq \mu E_c \cap [c, y] \geq \tfrac{2}{3}(y - c) \geq \tfrac{1}{2}(y - x_{n_k}).$$

But this means that $h(x_{n_k}) \geq y$, so that

$$x_{n_{k+1}} \leq c < \frac{1}{2}(x_{n_k} + h(x_{n_k})),$$

contrary to the choice of $x_{n_k+1}, \ldots, x_{n_{k+1}}$. **X**

Thus $c = b$. We therefore have a $j \in \mathbb{N}$ such that $x_j \frown b$, and $a = x_0 \frown \ldots \frown x_j \frown b$.

(c) Now suppose that $C \in \mathcal{C}$. Set $a = \inf C$ and $b = \sup C$. If $a = b$, then $\boldsymbol{t} = \{(a, C)\} \in T$ and $W_{\boldsymbol{t}} = C$. Otherwise, (b) tells us that we have $x_0, \ldots, x_n$ such that $a = x_0 \frown \ldots \frown x_n = b$. Choose $a_i \in [x_{i-1}, x_i] \cap E_{x_{i-1}} \cap E_{x_i}$ for $1 \leq i \leq n$. Set $C_i = [a_i, a_{i+1}[$ for $1 \leq i < n$, $C_0 = [a, a_1[$, $C_n = [a_n, b]$; set $I = \{i : i \leq n, C \cap C_i \neq \emptyset\}$; and check that $(x_i, C \cap C_i) \in \delta$ for $i \in I$, so that $\boldsymbol{t} = \{(x_i, C \cap C_i) : i \in I\}$ is a δ-fine member of T with $W_{\boldsymbol{t}} = C$. As C and δ are arbitrary, 481G(vii) is satisfied.

481X Basic exercises (a) Let X, $\mathcal{C}$, T and $\mathcal{F}$ be as in 481C. Show that if $f : X \to \mathbb{R}$, $\mu : \mathcal{C} \to \mathbb{R}$ and $\nu : \mathcal{C} \to \mathbb{R}$ are functions, then $I_{\mu+\nu}(f) = I_\mu(f) + I_\nu(f)$ whenever the right-hand side is defined.

>(b) Let I be any set. Set $T = \{\{(i, \{i\}) : i \in J\} : J \in [I]^{<\omega}\}$, $\delta = \{(i, \{i\}) : i \in I\}$, $\Delta = \{\delta\}$. For $J \in [I]^{<\omega}$ set $\mathcal{R}_J = \{I \setminus K : J \subseteq K \in [I]^{<\omega}\} \cup \{\emptyset\}$; set $\mathfrak{R} = \{\mathcal{R}_J : J \in [I]^{<\omega}\}$. Show that $(I, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions, witnessed by $[I]^{<\omega}$. Let $\nu : [I]^{<\omega} \to \mathbb{R}$ be any additive functional. Show that, for a function $f : I \to \mathbb{R}$, $\lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\mathfrak{R})} S_{\boldsymbol{t}}(f, \nu) = \sum_{i \in I} f(i)\nu(\{i\})$ if either exists in $\mathbb{R}$.

>(c) Set $T = \{\{(n, \{n\}) : n \in I\} : I \in [\mathbb{Z}]^{<\omega}\}$, $\delta = \{(n, \{n\}) : n \in \mathbb{Z}\}$, $\Delta = \{\delta\}$. For $I \in [\mathbb{Z}]^{<\omega}$ and $m, n \in \mathbb{N}$ set $R_{mn} = \mathbb{Z} \setminus \{i : -m \leq i \leq n\}$, $\mathcal{R}'_n = \{R_{kl} : k, l \geq n\} \cup \{\emptyset\}$, $\mathcal{R}''_n = \{R_{kk} : k \geq n\} \cup \{\emptyset\}$, $\mathfrak{R}' = \{\mathcal{R}'_n : n \in \mathbb{N}\}$, $\mathfrak{R}'' = \{\mathcal{R}''_n : n \in \mathbb{N}\}$. Show that $(\mathbb{Z}, T, \Delta, \mathfrak{R}')$ and $(\mathbb{Z}, T, \Delta, \mathfrak{R}'')$ are tagged-partition structures allowing subdivisions, witnessed by $[\mathbb{Z}]^{<\omega}$. Let μ be counting measure on $\mathbb{Z}$. Show that, for a function $f : \mathbb{Z} \to \mathbb{R}$, (i) $\lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\mathfrak{R}')} S_{\boldsymbol{t}}(f, \mu) = \lim_{m,n \to \infty} \sum_{i=-m}^{n} f(i)$ if either is defined in $\mathbb{R}$ (ii) $\lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\mathfrak{R}'')} S_{\boldsymbol{t}}(f, \mu) = \lim_{n \to \infty} \sum_{i=-n}^{n} f(i)$ if either is defined in $\mathbb{R}$.

(d) Set $X = \mathbb{N} \cup \{\infty\}$, and let T be the straightforward set of tagged partitions generated by $\{(n, \{n\}) : n \in \mathbb{N}\} \cup \{(\infty, X \setminus n) : n \in \mathbb{N}\}$ (interpreting a member of $\mathbb{N}$ as the set of its predecessors). For $n \in \mathbb{N}$ set $\delta_n = \{(i, \{i\}) : i \in \mathbb{N}\} \cup \{(\infty, A) : A \subseteq X \setminus n\}$; set $\Delta = \{\delta_n : n \in \mathbb{N}\}$. Show that $(X, T, \Delta, \{\{\emptyset\}\})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C} = [\mathbb{N}]^{<\omega} \cup \{X \setminus I : I \in [\mathbb{N}]^{<\omega}\}$. Let $h : \mathbb{N} \to \mathbb{R}$ be

any function, and define $\nu : \mathcal{C} \to \mathbb{R}$ by setting $\nu I = \sum_{i \in I} h(i)$, $\nu(X \setminus I) = -\nu I$ for $I \in [\mathbb{N}]^{<\omega}$. Let $f : X \to \mathbb{R}$ be any function such that $f(\infty) = 0$. Show that $\lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\{\{\emptyset\}\})} S_{\boldsymbol{t}}(f,\mu) = \lim_{n \to \infty} \sum_{i=0}^{n} f(i)h(i)$ if either is defined in $\mathbb{R}$.

>(e) Take X, T, Δ and $\mathfrak{R}$ as in 481I. Show that if μ is Lebesgue measure on $[a,b]$ then the gauge integral $I_\mu = \lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\mathfrak{R})} S_{\boldsymbol{t}}(.,\mu)$ is the ordinary Riemann integral $\int_a^b$ as described in 134K. (*Hint*: show first that they agree on step-functions.)

>(f) Let (X, Σ, μ) be a semi-finite measure space, and let Σ^f be the family of measurable sets of finite measure. Let T be the straightforward set of tagged partitions generated by $\{(x,E) : x \in E \in \Sigma^f\}$. For $E \in \Sigma^f$ and $\epsilon > 0$ set $\mathcal{R}_{E\epsilon} = \{F : F \in \Sigma, \mu(E \setminus F) \leq \epsilon\}$; set $\mathfrak{R} = \{\mathcal{R}_{E\epsilon} : E \in \Sigma^f, \epsilon > 0\}$. Let $\mathfrak{E}$ be the family of countable partitions of X into measurable sets, and set $\delta_{\mathcal{E}} = \bigcup_{E \in \mathcal{E}} \{(x,A) : x \in E, A \subseteq E\}$ for $\mathcal{E} \in \mathfrak{E}$, $\Delta = \{\delta_{\mathcal{E}} : \mathcal{E} \in \mathfrak{E}\}$. Show that $(X, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions, witnessed by Σ^f. Show that, for a function $f : X \to \mathbb{R}$, $\int f d\mu = \lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\mathfrak{R})} S_{\boldsymbol{t}}(f,\mu)$ if either is defined in $\mathbb{R}$. (*Hint*: when showing that if $I_\mu(f)$ is defined then f is μ-virtually measurable, you will need 413G or something similar; compare 482E.)

(g) Let (X, Σ, μ) be a totally finite measure space, and T the straightforward set of tagged partitions generated by $\{(x,E) : x \in E \in \Sigma\}$. Let $\mathfrak{E}$ be the family of finite partitions of X into measurable sets, and set $\delta_{\mathcal{E}} = \bigcup_{E \in \mathcal{E}} \{(x,A) : x \in E, A \subseteq E\}$ for $\mathcal{E} \in \mathfrak{E}$, $\Delta = \{\delta_{\mathcal{E}} : \mathcal{E} \in \mathfrak{E}\}$. Show that $(X, T, \Delta, \{\{\emptyset\}\})$ is a tagged-partition structure allowing subdivisions, witnessed by Σ. Show that, for a function $f : X \to \mathbb{R}$, $I_\mu(f) = \lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\mathfrak{R})} S_{\boldsymbol{t}}(f,\mu)$ is defined iff $f \in \mathcal{L}^\infty(\mu)$ (definition: 243A), and that then $I_\mu(f) = \int f d\mu$.

(h) Let X be a zero-dimensional compact Hausdorff space and $\mathcal{E}$ the algebra of open-and-closed subsets of X. Let T be the straightforward set of tagged partitions generated by $\{(x,E) : x \in E \in \mathcal{E}\}$. Let Δ be the set of all neighbourhood gauges on X. Show that $(X, T, \Delta, \{\{\emptyset\}\})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{E}$. Now let $\nu : \mathcal{E} \to \mathbb{R}$ be an additive functional, and set $I_\nu(f) = \lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\{\{\emptyset\}\})} S_{\boldsymbol{t}}(f,\nu)$ when $f : X \to \mathbb{R}$ is such that the limit is defined. (i) Show that $I_\nu(\chi E) = \nu E$ for every $E \in \mathcal{E}$. (ii) Show that if ν is bounded then $I_\nu(f)$ is defined for every $f \in C(X)$.

(i) Let X be a set, Δ a set of gauges on X, $\mathfrak{R}$ a collection of families of subsets of X, and T a set of tagged partitions on X which is compatible with Δ and $\mathfrak{R}$. Let $H \subseteq X$ be such that there is a $\tilde{\delta} \in \Delta$ such that $H \cap A = \emptyset$ whenever $x \in X \setminus H$ and $(x,A) \in \tilde{\delta}$, and set $\delta_H = \{(x, A \cap H) : x \in H, (x,A) \in \delta\}$ for $\delta \in \Delta$, $\Delta_H = \{\delta_H : \delta \in \Delta\}$, $\mathfrak{R}_H = \{\{R \cap H : R \in \mathcal{R}\} : \mathcal{R} \in \mathfrak{R}\}$, $T_H = \{\{(x, C \cap H) : (x,C) \in \boldsymbol{t}, x \in H\} : \boldsymbol{t} \in T\}$. Show that T_H is compatible with Δ_H and $\mathfrak{R}_H$.

481Y Further exercises (a) Suppose that $[a,b]$, $\mathcal{C}$, T and Δ are as in 481J. Let $T' \subseteq [[0,1] \times \mathcal{C}]^{<\omega}$ be the set of tagged partitions $\boldsymbol{t} = \{(x_i, [a_i, a_{i+1}]) : i < n\}$ where $a = a_0 \leq x_0 \leq a_1 \leq x_2 \leq a_2 \leq \ldots \leq x_{n-1} \leq a_n = b$. Show that T', as well as T, is compatible with Δ in the sense of 481E; let $\mathcal{F}'$, $\mathcal{F}$ be the corresponding filters on T' and T. Show that if $\nu : \mathcal{C} \to \mathbb{R}$ is a functional which is additive in the sense that $\nu(C \cup C') = \nu C + \nu C'$ whenever C, C' are disjoint members of $\mathcal{C}$ with union in $\mathcal{C}$, and if $\nu\{x\} = 0$ for every $x \in [a,b]$ and $f : [a,b] \to \mathbb{R}$ is any function, then $I'_\nu(f) = I_\nu(f)$ if either is defined, where

$$I_\nu(f) = \lim_{\boldsymbol{t} \to \mathcal{F}} S_{\boldsymbol{t}}(f,\nu), \quad I'_\nu(f) = \lim_{\boldsymbol{t} \to \mathcal{F}'} S_{\boldsymbol{t}}(f,\nu)$$

are the gauge integrals associated with $(T, \mathcal{F})$ and $(T', \mathcal{F}')$.

(b) Let us say that a family $\mathfrak{R}$ of residual families is 'the simple residual structure complementary to $\mathcal{H} \subseteq \mathcal{P}X$' if $\mathfrak{R} = \{\mathcal{R}_H : H \in \mathcal{H}\}$, where $\mathcal{R}_H = \{X \setminus H' : H \subseteq H' \in \mathcal{H}\} \cup \{\emptyset\}$ for each $H \in \mathcal{H}$. Suppose that, for each member i of a non-empty finite set I, $(X_i, T_i, \Delta_i, \mathfrak{R}_i)$ is a tagged-partition structure allowing subdivisions, witnessed by an upwards-directed family $\mathcal{C}_i \subseteq \mathcal{P}X_i$, where X_i is a topological space, Δ_i is the set of all neighbourhood gauges on X_i, and $\mathfrak{R}_i$ is the simple residual structure complementary to $\mathcal{C}_i$. Set $X = \prod_{i \in I} X_i$ and let Δ be the set of neighbourhood gauges on X; let $\mathcal{C}$ be $\{\prod_{i \in I} C_i : C_i \in \mathcal{C}_i \text{ for each } i \in I\}$, and $\mathfrak{R}$ the simple residual structure based on $\mathcal{C}$; and let T be the straightforward set of tagged partitions generated by $\{(\langle x_i \rangle_{i \in I}, \prod_{i \in I} C_i) : \{(x_i, C_i)\} \in T_i \text{ for every } i \in I\}$. Show that $(X, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$.

(c) Give an example to show that, in 481Xi, $(X, T, \Delta, \Re)$ can be a tagged-partition structure allowing subdivisions, while $(H, T_H, \Delta_H, \Re_H)$ is not.

481 Notes and comments In the examples above I have tried to give an idea of the potential versatility of the ideas here. Further examples may be found in HENSTOCK 91. The goal of 481A-481F is the formula $I_\nu(f) = \lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\Re)} S_{\boldsymbol{t}}(f, \nu)$; the elaborate notation reflects the variety of the applications. One of these is a one-step definition of the ordinary integral (481Xf). In §483 I will show that the Henstock integral (481J) properly extends the Lebesgue integral on $\mathbb{R}$. In 481Xc I show how adjusting $\Re$ can change the class of integrable functions; in 481Xd I show how a similar effect can sometimes be achieved by adding a point at infinity and adjusting T and Δ. As will become apparent in later sections, one of the great strengths of gauge integrals is their ability to incorporate special limiting processes. Another is the fact that we don't need to assume that the functionals ν are countably additive; see 481Xd. In the formulae of this section, I don't even ask for finite additivity; but of course the functional I_ν is likely to have a rather small domain if ν behaves too erratically.

'Gauges', as I describe them here, have moved rather briskly forward from the metric gauges δ_h (481E), which have sufficed for most of the gauge integrals so far described. But the generalization affects only the notation, and makes it clear why so much of the theory of the ordinary Henstock integral applies equally well to the 'approximately continuous Henstock integral' (481Q), for instance. You will observe that the sets Q of 481Ba are just 'gauges' in the wide sense used here. But (as the examples of this section show clearly) we generally use them in a different way.

In ordinary measure theory, we have a fairly straightforward theory of subspaces (§214) and a rather deeper theory of product spaces (chap. 25). For gauge integrals, there are significant difficulties in the theory of subspaces, some of which will appear in the next section (see 482G-482H). For closed subspaces, something can be done, as in 481Xi; but the procedure suggested there may lose some essential element of the original tagged-partition structure (481Yc). For products of gauge integrals, we do have a reasonably satisfying version of Fubini's theorem (482M); I offer 481O and 481P as alternative approaches.

You will note the concentration on 'neighbourhood gauges' in the work above. The set Δ of all neighbourhood gauges on a topological space X has the following special property: if $x \mapsto \delta_x : X \to \Delta$ is any function, then $\{(x, A) : x \in X, (x, A) \in \delta_x\}$ belongs to Δ. By analogy with the notion of 'full group of automorphisms' (381Be), we might say that a set Δ of gauges is 'full' if it has this property, and 'countably full' if whenever $\langle \delta_n \rangle_{n \in \mathbb{N}}$ is a sequence in Δ, and $\phi : X \to \mathbb{N}$ is a function, then $\{(x, A) : x \in X, (x, A) \in \delta_{\phi(x)}\}$ belongs to Δ. As will appear repeatedly in the next section, this kind of flexibility in constructing gauges is just what one needs when proving that functions are gauge-integrable.

While I have used such phrases as 'Henstock integral', 'symmetric Riemann-complete integral' above, I have not in fact discussed integrals here, except in the exercises; in most of the examples in 481I-481Q there is no mention of any functional ν from which a gauge integral I_ν can be defined. The essence of the method is that we can set up a tagged-partition structure quite independently of any set function, and it turns out that the properties of a gauge integral depend more on this structure than on the measure involved.

482 General theory

I turn now to results which can be applied to a wide variety of tagged-partition structures. The first step is a 'Saks-Henstock' lemma (482B), a fundamental property of tagged-partition structures allowing subdivisions. In order to relate gauge integrals to the ordinary integrals treated elsewhere in this treatise, we need to know when gauge-integrable functions are measurable (482E) and when integrable functions are gauge-integrable (482F). There are significant difficulties when we come to interpret gauge integrals over subspaces, but I give partial results in 482G and 482L. 482J, 482K and 482M are gauge-integral versions of the fundamental theorem of calculus, B.Levi's theorem and Fubini's theorem, while 482H is a new theorem on integrability of a limit function.

Henstock's integral (481J-481K) remains the most important example and the natural test case for the ideas here; I will give the details in the next section, and you may wish to take the two sections in parallel.

482A Lemma Suppose that $(X, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions (481G), witnessed by $\mathcal{C} \subseteq \mathcal{P}X$.

(a) Whenever $\delta \in \Delta$, $\mathcal{R} \in \mathfrak{R}$ and E belongs to the subalgebra of $\mathcal{P}X$ generated by $\mathcal{C}$, there is a δ-fine $\boldsymbol{s} \in T$ such that $W_{\boldsymbol{s}} \subseteq E$ and $E \setminus W_{\boldsymbol{s}} \in \mathcal{R}$.

(b) Whenever $\delta \in \Delta$, $\mathcal{R} \in \mathfrak{R}$ and $\boldsymbol{t} \in T$ is δ-fine, there is a δ-fine $\mathcal{R}$-filling $\boldsymbol{t}' \in T$ including $\boldsymbol{t}$.

(c) Suppose that $f : X \to \mathbb{R}$, $\nu : \mathcal{C} \to \mathbb{R}$, $\delta \in \Delta$, $\mathcal{R} \in \mathfrak{R}$ and $\epsilon \geq 0$ are such that $|S_{\boldsymbol{t}}(f, \nu) - S_{\boldsymbol{t}'}(f, \nu)| \leq \epsilon$ whenever $\boldsymbol{t}$, $\boldsymbol{t}' \in T$ are δ-fine and $\mathcal{R}$-filling. Then

(i) $|S_{\boldsymbol{t}}(f, \nu) - S_{\boldsymbol{t}'}(f, \nu)| \leq \epsilon$ whenever $\boldsymbol{t}$, $\boldsymbol{t}' \in T$ are δ-fine and $W_{\boldsymbol{t}} = W_{\boldsymbol{t}'}$;

(ii) whenever $\boldsymbol{t} \in T$ is δ-fine, and $\delta' \in \Delta$, there is a δ'-fine $\boldsymbol{s} \in T$ such that $W_{\boldsymbol{s}} \subseteq W_{\boldsymbol{t}}$ and $|S_{\boldsymbol{s}}(f, \nu) - S_{\boldsymbol{t}}(f, \nu)| \leq \epsilon$.

(d) Suppose that $f : X \to [0, \infty[$ and $\nu : \mathcal{C} \to [0, \infty[$ are such that $I_\nu(f) = \lim_{\boldsymbol{t} \to \mathcal{F}(T, \Delta, \mathfrak{R})} S_{\boldsymbol{t}}(f, \nu)$ is defined. Then for any $\epsilon > 0$ there is a $\delta \in \Delta$ such that $S_{\boldsymbol{t}}(f, \nu) \leq I_\nu(f) + \epsilon$ for every δ-fine $\boldsymbol{t} \in T$.

proof (a) By 481He, there is a non-increasing sequence $\langle \mathcal{R}_k \rangle_{k \in \mathbb{N}}$ in $\mathfrak{R}$ such that $\bigcup_{i \leq k} A_i \in \mathcal{R}$ whenever $A_i \in \mathcal{R}_i$ for every $i \leq k$ and $\langle A_i \rangle_{i \leq k}$ is disjoint. Let $\mathcal{C}_0$ be a finite subset of $\mathcal{C}$ such that E belongs to the subalgebra of $\mathcal{P}X$ generated by $\mathcal{C}_0$, and let $\mathcal{C}_1 \supseteq \mathcal{C}_0$ be a finite subset of $\mathcal{C}$ such that $X \setminus W \in \mathcal{R}_0$, where $W = \bigcup \mathcal{C}_1$ (481G(v)). Then either $E \subseteq W$ or $E \supseteq X \setminus W$. In either case, $E \cap W$ belongs to the ring generated by $\mathcal{C}$, so is expressible as $\bigcup_{i<n} C_i$ where $\langle C_i \rangle_{i<n}$ is a disjoint family in $\mathcal{C}$ (481Hd).

For each $i < n$, let $\boldsymbol{s}_i$ be a δ-fine member of T such that $W_{\boldsymbol{s}_i} \subseteq C_i$ and $C_i \setminus W_{\boldsymbol{s}_i} \in \mathcal{R}_{i+1}$ (481G(vii)). Set $\boldsymbol{s} = \bigcup_{i<n} \boldsymbol{s}_i$. Because $\langle W_{\boldsymbol{s}_i} \rangle_{i<n}$ is disjoint and T is a straightforward set of tagged partitions, $\boldsymbol{s} \in T$; $\boldsymbol{s}$ is δ-fine because every $\boldsymbol{s}_i$ is; $W_{\boldsymbol{s}} = \bigcup_{i<n} W_{\boldsymbol{s}_i}$ is included in E; and $E \setminus W_{\boldsymbol{s}}$ is either $\bigcup_{i<n} C_i \setminus W_{\boldsymbol{s}_i}$ or $(X \setminus W) \cup \bigcup_{i<n} (C_i \setminus W_{\boldsymbol{s}_i})$, and in either case belongs to $\mathcal{R}$, by the choice of $\langle \mathcal{R}_n \rangle_{n \in \mathbb{N}}$.

(b) Set $E = X \setminus W_{\boldsymbol{t}}$. By (a), there is a δ-fine $\boldsymbol{s} \in T$ such that $W_{\boldsymbol{s}} \subseteq E$ and $E \setminus W_{\boldsymbol{s}} \in \mathcal{R}$. Set $\boldsymbol{t}' = \boldsymbol{t} \cup \boldsymbol{s}$; this works.

(c)(i) As in (b), there is a δ-fine $\boldsymbol{s} \in T$ such that $W_{\boldsymbol{s}} \cap W_{\boldsymbol{t}} = \emptyset$ and $\boldsymbol{t} \cup \boldsymbol{s}$ is $\mathcal{R}$-filling. Now $W_{\boldsymbol{t} \cup \boldsymbol{s}} = W_{\boldsymbol{t}' \cup \boldsymbol{s}}$, so $\boldsymbol{t}' \cup \boldsymbol{s}$ is also $\mathcal{R}$-filling, and

$$|S_{\boldsymbol{t}}(f, \nu) - S_{\boldsymbol{t}'}(f, \nu)| = |S_{\boldsymbol{t} \cup \boldsymbol{s}}(f, \nu) - S_{\boldsymbol{t}' \cup \boldsymbol{s}}(f, \nu)| \leq \epsilon.$$

(ii) Replacing δ' by a lower bound of $\{\delta, \delta'\}$ in Δ if necessary, we may suppose that $\delta' \subseteq \delta$. Enumerate $\boldsymbol{t}$ as $\langle (x_i, C_i) \rangle_{i<n}$. Let $\langle \mathcal{R}_k \rangle_{k \in \mathbb{N}}$ be a sequence in $\mathfrak{R}$ such that $\bigcup_{i \leq k} A_i \in \mathcal{R}$ whenever $\langle A_i \rangle_{i \leq k}$ is disjoint and $A_i \in \mathcal{R}_i$ for every $i \leq k$. For each $i < n$, let $\boldsymbol{s}_i$ be a δ'-fine member of T such that $W_{\boldsymbol{s}_i} \subseteq C_i$ and $C_i \setminus W_{\boldsymbol{s}_i} \in \mathcal{R}_{i+1}$, and set $\boldsymbol{s} = \bigcup_{i<n} \boldsymbol{s}_i$, so that $\boldsymbol{s} \in T$ is δ'-fine. By (a), there is a δ-fine $\boldsymbol{u} \in T$ such that $W_{\boldsymbol{u}} \cap W_{\boldsymbol{t}} = \emptyset$ and $X \setminus (W_{\boldsymbol{t}} \cup W_{\boldsymbol{u}}) \in \mathcal{R}_0$. Set $\boldsymbol{t}' = \boldsymbol{t} \cup \boldsymbol{u}$, $\boldsymbol{s}' = \boldsymbol{s} \cup \boldsymbol{u}$; then $\boldsymbol{t}'$ and $\boldsymbol{s}'$ are δ-fine and $\mathcal{R}$-filling, because

$$X \setminus W_{\boldsymbol{s}'} = (X \setminus (W_{\boldsymbol{t}} \cup W_{\boldsymbol{u}})) \cup \bigcup_{i<n} (C_i \setminus W_{\boldsymbol{s}_i}) \in \mathcal{R},$$

by the choice of $\langle \mathcal{R}_k \rangle_{k \in \mathbb{N}}$. So

$$|S_{\boldsymbol{t}}(f, \nu) - S_{\boldsymbol{s}}(f, \nu)| = |S_{\boldsymbol{t}'}(f, \nu) - S_{\boldsymbol{s}'}(f, \nu)| \leq \epsilon,$$

as required.

(d) There are $\delta \in \Delta$, $\mathcal{R} \in \mathfrak{R}$ such that $|S_{\boldsymbol{t}}(f, \nu) - I_\nu(f)| \leq \epsilon$ whenever $\boldsymbol{t} \in T$ is δ-fine and $\mathcal{R}$-filling. If $\boldsymbol{t} \in T$ is an arbitrary δ-fine tagged partition, there is a δ-fine $\mathcal{R}$-filling $\boldsymbol{t}' \supseteq \boldsymbol{t}$, by (b), so

$$S_{\boldsymbol{t}}(f, \nu) \leq S_{\boldsymbol{t}'}(f, \nu) \leq I_\nu(f) + \epsilon,$$

as claimed.

482B Saks-Henstock Lemma Let $(X, T, \Delta, \mathfrak{R})$ be a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$, and $f : X \to \mathbb{R}$, $\nu : \mathcal{C} \to \mathbb{R}$ functions such that $I_\nu(f) = \lim_{\boldsymbol{t} \to \mathcal{F}(T, \Delta, \mathfrak{R})} S_{\boldsymbol{t}}(f, \nu)$ is defined. Let $\mathcal{E}$ be the algebra of subsets of X generated by $\mathcal{C}$. Then there is a unique additive functional $F : \mathcal{E} \to \mathbb{R}$ such that for every $\epsilon > 0$ there are $\delta \in \Delta$ and $\mathcal{R} \in \mathfrak{R}$ such that

(α) $\sum_{(x,C) \in \boldsymbol{t}} |F(C) - f(x) \nu C| \leq \epsilon$ for every δ-fine $\boldsymbol{t} \in T$,

(β) $|F(E)| \leq \epsilon$ whenever $E \in \mathcal{E} \cap \mathcal{R}$.

Moreover, $F(X) = I_\nu(f)$.

proof (a) For $E \in \mathcal{E}$, write T_E for the set of those $\boldsymbol{t} \in T$ such that, for every $(x, C) \in \boldsymbol{t}$, either $C \subseteq E$ or $C \cap E = \emptyset$. For any $\delta \in \Delta$, $\mathcal{R} \in \mathfrak{R}$ and finite $\mathcal{D} \subseteq \mathcal{E}$ there is a δ-fine $\boldsymbol{t} \in \bigcap_{E \in \mathcal{D}} T_E$ such that $E \setminus W_{\boldsymbol{t}} \in \mathcal{R}$ for every $E \in \mathcal{D}$. **P** Let $\langle \mathcal{R}_n \rangle_{n \in \mathbb{N}}$ be a sequence in $\mathfrak{R}$ such that whenever $A_i \in \mathcal{R}_i$ for $i \leq n$ and $\langle A_i \rangle_{i \leq n}$ is disjoint then $\bigcup_{i \leq n} A_i \in \mathcal{R}$ (481He). Let $\mathcal{E}_0$ be the subalgebra of $\mathcal{E}$ generated by $\mathcal{D}$, and enumerate the atoms of $\mathcal{E}_0$ as $\langle E_i \rangle_{i<n}$. By 482Aa, there is for each $i < n$ a δ-fine $\boldsymbol{s}_i \in T$ such that $W_{\boldsymbol{s}_i} \subseteq E_i$ and $E_i \setminus W_{\boldsymbol{s}_i} \in \mathcal{R}_i$. Set $\boldsymbol{t} = \bigcup_{i<n} \boldsymbol{s}_i$. If $E \in \mathcal{D}$ then $E = \bigcup_{i \in J} E_i$ for some $J \subseteq n$. For any $(x, C) \in \boldsymbol{t}$, there is some $i < n$ such that $C \subseteq E_i$, so that $C \subseteq E$ if $i \in J$, $C \cap E = \emptyset$ otherwise; thus $\boldsymbol{t} \in T_E$. Moreover, $E \setminus W_{\boldsymbol{t}} = \bigcup_{i \in J} (E_i \setminus W_{\boldsymbol{s}_i})$ belongs to $\mathcal{R}$. **Q**

(b) We therefore have a filter $\mathcal{F}^*$ on T generated by sets of the form

$$T_{E\delta\mathcal{R}} = \{\boldsymbol{t} : \boldsymbol{t} \in T_E \text{ is } \delta\text{-fine}, E \setminus W_{\boldsymbol{t}} \in \mathcal{R}\}$$

as δ runs over Δ, $\mathcal{R}$ runs over $\mathfrak{R}$ and E runs over $\mathcal{E}$. For $\boldsymbol{t} \in T$, $E \subseteq X$ set $\boldsymbol{t}_E = \{(x, C) : (x, C) \in \boldsymbol{t}, C \subseteq E\}$. Now $F(E) = \lim_{\boldsymbol{t} \to \mathcal{F}^*} S_{\boldsymbol{t}_E}(f, \nu)$ is defined for every $E \in \mathcal{E}$. **P** For any $\epsilon > 0$, there are $\delta \in \Delta$, $\mathcal{R} \in \mathfrak{R}$ such that $|I_\nu(f) - S_{\boldsymbol{t}}(f, \nu)| \leq \epsilon$ for every δ-fine $\mathcal{R}$-filling $\boldsymbol{t} \in T$. Let $\mathcal{R}' \in \mathfrak{R}$ be such that $A \cup B \in \mathcal{R}$ for all disjoint A, $B \in \mathcal{R}'$. If $\boldsymbol{t}$, $\boldsymbol{t}'$ belong to $T_{E,\delta,\mathcal{R}'} = T_{X \setminus E,\delta,\mathcal{R}'}$, then set

$$\boldsymbol{s} = \{(x, C) : (x, C) \in \boldsymbol{t}', C \subseteq E\} \cup \{(x, C) : (x, C) \in \boldsymbol{t}, C \cap E = \emptyset\}.$$

Then $\boldsymbol{s} \in T_E$ is δ-fine, and also $E \setminus W_{\boldsymbol{s}} = E \setminus W_{\boldsymbol{t}'}$, $(X \setminus E) \setminus W_{\boldsymbol{s}} = (X \setminus E) \setminus W_{\boldsymbol{t}}$ both belong to $\mathcal{R}'$; so their union $X \setminus W_{\boldsymbol{s}}$ belongs to $\mathcal{R}$, and $\boldsymbol{s}$ is $\mathcal{R}$-filling. Accordingly

$$\begin{aligned} |S_{\boldsymbol{t}_E}(f, \nu) - S_{\boldsymbol{t}'_E}(f, \nu)| &= |S_{\boldsymbol{t}}(f, \nu) - S_{\boldsymbol{s}}(f, \nu)| \\ &\leq |S_{\boldsymbol{t}}(f, \nu) - I_\nu(f)| + |I_\nu(f) - S_{\boldsymbol{s}}(f, \nu)| \leq 2\epsilon. \end{aligned}$$

As ϵ is arbitrary, this is enough to show that $\liminf_{\boldsymbol{t} \to \mathcal{F}^*} S_{\boldsymbol{t}_E}(f, \nu) = \limsup_{\boldsymbol{t} \to \mathcal{F}^*} S_{\boldsymbol{t}_E}(f, \nu)$, so that the limit $\lim_{\boldsymbol{t} \to \mathcal{F}^*} S_{\boldsymbol{t}_E}(f, \nu)$ is defined (2A3S). **Q**

(c) If E, $E' \in \mathcal{E}$ are disjoint, then

$$S_{\boldsymbol{t}_{E \cup E'}}(f, \nu) = S_{\boldsymbol{t}_E}(f, \nu) + S_{\boldsymbol{t}_{E'}}(f, \nu)$$

for any $\boldsymbol{t} \in T_E \cap T_{E'}$; since both T_E and $T_{E'}$ belong to $\mathcal{F}^*$, $F(E \cup E') = F(E) + F(E')$. Thus F is additive.

(d) Now suppose that $\epsilon > 0$. Let $\delta \in \Delta$, $\mathcal{R}^* \in \mathfrak{R}$ be such that $|I_\nu(f) - S_{\boldsymbol{t}}(f, \nu)| \leq \frac{1}{4}\epsilon$ for every δ-fine, $\mathcal{R}^*$-filling $\boldsymbol{t} \in T$. Let $\mathcal{R} \in \mathfrak{R}$ be such that $A \cup B \in \mathcal{R}^*$ for all disjoint A, $B \in \mathcal{R}$.

(i) If $\boldsymbol{t} \in T$ is δ-fine, then $|F(W_{\boldsymbol{t}}) - S_{\boldsymbol{t}}(f, \nu)| \leq \frac{1}{2}\epsilon$. **P** For any $\eta > 0$, there is a δ-fine $\boldsymbol{s} \in T$ such that
$|I_\nu(f) - S_{\boldsymbol{s}}(f, \nu)| \leq \eta$,
for every $(x, C) \in \boldsymbol{s}$, either $C \subseteq W_{\boldsymbol{t}}$ or $C \cap W_{\boldsymbol{t}} = \emptyset$,
$(X \setminus W_{\boldsymbol{t}}) \setminus W_{\boldsymbol{s}} \in \mathcal{R}$, $W_{\boldsymbol{t}} \setminus W_{\boldsymbol{s}} \in \mathcal{R}$,
$|F(W_{\boldsymbol{t}}) - \sum_{(x,C) \in \boldsymbol{s}, C \subseteq W_{\boldsymbol{t}}} f(x)\nu C| \leq \eta$
because the set of $\boldsymbol{s}$ with these properties belongs to $\mathcal{F}^*$. Now, setting $\boldsymbol{s}_1 = \{(x, C) : (x, C) \in \boldsymbol{s}, C \subseteq W_{\boldsymbol{t}}\}$ and $\boldsymbol{t}' = \boldsymbol{t} \cup \boldsymbol{s} \setminus \boldsymbol{s}_1$, $\boldsymbol{t}'$ is δ-fine and $\mathcal{R}^*$-filling, like $\boldsymbol{s}$, so

$$\begin{aligned} |F(W_{\boldsymbol{t}}) - S_{\boldsymbol{t}}(f, \nu)| &\leq |F(W_{\boldsymbol{t}}) - S_{\boldsymbol{s}_1}(f, \nu)| + |S_{\boldsymbol{s}_1}(f, \nu) - S_{\boldsymbol{t}}(f, \nu)| \\ &\leq \eta + |S_{\boldsymbol{s}}(f, \nu) - S_{\boldsymbol{t}'}(f, \nu)| \\ &\leq \eta + |S_{\boldsymbol{s}}(f, \nu) - I_\nu(f)| + |I_\nu(f) - S_{\boldsymbol{t}'}(f, \nu)| \leq \eta + \frac{1}{2}\epsilon. \end{aligned}$$

As η is arbitrary we have the result. **Q**

(ii) So if $\boldsymbol{t} \in T$ is δ-fine, $\sum_{(x,C) \in \boldsymbol{t}} |F(C) - f(x)\nu C| \leq \epsilon$. **P** Set $\boldsymbol{t}' = \{(x, C) : (x, C) \in \boldsymbol{t}, F(C) \leq f(x)\nu C\}$, $\boldsymbol{t}'' = \boldsymbol{t} \setminus \boldsymbol{t}''$. Then both $\boldsymbol{t}'$ and $\boldsymbol{t}''$ are δ-fine, so

$$\begin{aligned} &\sum_{(x,C) \in \boldsymbol{t}} |F(C) - f(x)\nu C| \\ &\quad = |\sum_{(x,C) \in \boldsymbol{t}'} F(C) - f(x)\nu C| + |\sum_{(x,C) \in \boldsymbol{t}''} F(C) - f(x)\nu C| \leq \epsilon. \end{aligned}$$ **Q**

(iii) Now suppose that $E \in \mathcal{E} \cap \mathcal{R}$. Then $|F(E)| \leq \epsilon$. **P** Let $\mathcal{R}' \in \mathfrak{R}$ be such that $A \cup B \in \mathcal{R}$ whenever A, $B \in \mathcal{R}'$ are disjoint. Let $\boldsymbol{t}$ be such that

$\boldsymbol{t} \in T_E$ is δ-fine,

$E \setminus W_{\boldsymbol{t}}$ and $(X \setminus E) \setminus W_{\boldsymbol{t}}$ both belong to $\mathcal{R}'$,

$|F(E) - S_{\boldsymbol{t}_E}(f, \nu)| \leq \frac{1}{2}\epsilon$;

once again, the set of candidates belongs to $\mathcal{F}^*$, so is not empty. Then $\boldsymbol{t}$ and $\boldsymbol{t}_{X \setminus E}$ are both $\mathcal{R}^*$-filling and δ-fine, so

$$\begin{aligned} |F(E)| &\leq \tfrac{1}{2}\epsilon + |S_{\boldsymbol{t}_E}(f, \nu)| \\ &= \tfrac{1}{2}\epsilon + |S_{\boldsymbol{t}}(f, \nu) - S_{\boldsymbol{t}_{X \setminus E}}(f, \nu)| \leq \epsilon. \end{aligned}$$ **Q**

As ϵ is arbitrary, this shows that F has all the required properties.

(d) I have still to show that F is unique. Suppose that $F' : \mathcal{E} \to \mathbb{R}$ is another functional with the same properties, and take $E \in \mathcal{E}$ and $\epsilon > 0$. Then there are δ, $\delta' \in \Delta$ and $\mathcal{R}$, $\mathcal{R}' \in \mathfrak{R}$ such that

$\sum_{(x,C) \in \boldsymbol{t}} |F(C) - f(x)\nu C| \leq \epsilon$ for every δ-fine $\boldsymbol{t} \in T$,

$\sum_{(x,C) \in \boldsymbol{t}} |F'(C) - f(x)\nu C| \leq \epsilon$ for every δ'-fine $\boldsymbol{t} \in T$,

$|F(R)| \leq \epsilon$ whenever $R \in \mathcal{E} \cap \mathcal{R}$,

$|F'(R)| \leq \epsilon$ whenever $R \in \mathcal{E} \cap \mathcal{R}'$.

Now taking $\delta'' \in \Delta$ such that $\delta'' \subseteq \delta \cap \delta'$, and $\mathcal{R}'' \in \mathfrak{R}$ such that $\mathcal{R}'' \subseteq \mathcal{R} \cap \mathcal{R}'$, there is a δ''-fine $\boldsymbol{t} \in T$ such that $E' = W_{\boldsymbol{t}}$ is included in E and $E \setminus E' \in \mathcal{R}''$. In this case

$$|F(E) - F'(E)| \leq |F(E \setminus E')| + \sum_{(x,C) \in \boldsymbol{t}} |F(C) - F'(C)| + |F'(E \setminus E')|$$

(because F and F' are both additive)

$$\leq 2\epsilon + \sum_{(x,C) \in \boldsymbol{t}} |F(C) - f(x)\nu C| + \sum_{(x,C) \in \boldsymbol{t}} |F'(C) - f(x)\nu C| \leq 4\epsilon.$$

As ϵ and E are arbitrary, $F = F'$, as required.

(e) Finally, to calculate $F(X)$, take any $\epsilon > 0$. Let $\delta \in \Delta$ and $\mathcal{R} \in \mathfrak{R}$ be such that $\sum_{(x,C) \in \boldsymbol{t}} |F(C) - f(x)\nu C| \leq \epsilon$ for every δ-fine $\boldsymbol{t} \in T$ and $|F(E)| \leq \epsilon$ whenever $E \in \mathcal{R}$. Let $\boldsymbol{t}$ be any δ-fine $\mathcal{R}$-filling member of T such that $S_{\boldsymbol{t}}(f, \nu) - I_\nu(f)| \leq \epsilon$. Then, because F is additive,

$$|F(X) - I_\nu(f)| \leq |F(X) - F(W_{\boldsymbol{t}})| + |\textstyle\sum_{(x,C) \in \boldsymbol{t}} F(C) - f(x)\nu C| + |S_{\boldsymbol{t}} - I_\nu(f)| \leq 3\epsilon.$$

As ϵ is arbitrary, $F(X) = I_\nu(f)$.

482C Definition In the context of 482B, I will call the function F the **Saks-Henstock indefinite integral** of f; of course it depends on the whole structure $(X, T, \Delta, \mathfrak{R}, \mathcal{C}, f, \nu)$ and not just on (X, f, ν). You should *not* take it for granted that $F(E) = I_\nu(f \times \chi E)$; but see 482G below.

482D The Saks-Henstock lemma characterizes the gauge integral, as follows.

Theorem Let $(X, T, \Delta, \mathfrak{R})$ be a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$, and $\nu : \mathcal{C} \to \mathbb{R}$ any function. Let $\mathcal{E}$ be the algebra of subsets of X generated by $\mathcal{C}$. If $f : X \to \mathbb{R}$ is any function, then the following are equiveridical:

(i) $I_\nu(f) = \lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\mathfrak{R})} S_{\boldsymbol{t}}(f, \nu)$ is defined in $\mathbb{R}$;

(ii) there is an additive functional $F : \mathcal{E} \to \mathbb{R}$ such that

(α) for every $\epsilon > 0$ there is a $\delta \in \Delta$ such that $\sum_{(x,C) \in \boldsymbol{t}} |F(C) - f(x)\mu C| \leq \epsilon$ for every δ-fine $\boldsymbol{t} \in T$,

(β) for every $\epsilon > 0$ there is an $\mathcal{R} \in \mathfrak{R}$ such that $|F(E)| \leq \epsilon$ for every $E \in \mathcal{E} \cap \mathcal{R}$.

proof (i)⇒(ii) is just 482B above; so let us assume (ii) and seek to prove (i). Given $\epsilon > 0$, take $\delta \in \Delta$ and $\mathcal{R} \in \mathfrak{R}$ such that (α) and (β) are satisfied. Let $\boldsymbol{t} \in T_\alpha$ be δ-fine and $\mathcal{R}$-filling. Then

$$|F(\mathbb{R}^r) - S_{\boldsymbol{t}}(f,\mu)| \leq |F(\mathbb{R}^r \setminus W_{\boldsymbol{t}})| + \sum_{(x,C)\in\boldsymbol{t}} |F(C) - f(x)\mu C|$$
$$\leq 2\epsilon.$$

As ϵ is arbitrary, $I_\nu(f)$ is defined and equal to $F(\mathbb{R}^r)$.

482E Theorem Let (X,ρ) be a metric space and μ a complete locally determined measure on X with domain Σ. Let $\mathcal{C}$, Q, T, Δ and $\mathfrak{R}$ be such that

(i) $\mathcal{C} \subseteq \Sigma$ and μC is finite for every $C \in \mathcal{C}$;

(ii) $Q \subseteq X \times \mathcal{C}$, and for $C \in \mathcal{C}$, $(x,C) \in Q$ for almost every $x \in C$;

(iii) T is the straightforward set of tagged partitions generated by Q;

(iv) Δ is a downwards-directed family of neighbourhood gauges on X containing all the uniform metric gauges;

(v) $\mathfrak{R}$ is a downwards-directed collection of families of subsets of X such that whenever $E \in \Sigma$, $\mu E < \infty$ and $\epsilon > 0$, there is an $\mathcal{R} \in \mathfrak{R}$ such that $\mu^*(E \cap R) \leq \epsilon$ for every $R \in \mathcal{R}$;

(vi) T is compatible with Δ and $\mathfrak{R}$.

Let $f : X \to \mathbb{R}$ be any function such that $I_\mu(f) = \lim_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\mathfrak{R})} S_{\boldsymbol{t}}(f,\mu)$ is defined. Then f is Σ-measurable.

proof ? Suppose, if possible, otherwise.

Because μ is complete and locally determined, there are a measurable set E of non-zero finite measure and $\alpha < \beta$ in $\mathbb{R}$ such that

$$\mu^*\{x : x \in E,\ f(x) \leq \alpha\} = \mu^*\{x : x \in E,\ f(x) \geq \beta\} = \mu E$$

(413G). Let $\epsilon > 0$ be such that $(\beta-\alpha)(\mu E - 3\epsilon) > 2\epsilon$. Let $\delta \in \Delta$, $\mathcal{R} \in \mathfrak{R}$ be such that $|S_{\boldsymbol{t}}(f,\mu) - I_\nu(f)| \leq \epsilon$ whenever $\boldsymbol{t} \in T$ is δ-fine and $\mathcal{R}$-filling. Let $\langle G_x\rangle_{x\in X}$ be a family of open sets such that $x \in G_x$ for every $x \in X$ and $\delta = \{(x,C) : x \in X,\ C \in \mathcal{C},\ C \subseteq G_x\}$. For $m \geq 1$, set

$$A_m = \{x : x \in E,\ f(x) \leq \alpha,\ U_{1/m}(x) \subseteq G_x\},$$

writing $U_{1/m}(x)$ for $\{y : \rho(y,x) < \frac{1}{m}\}$,

$$B_m = \{x : x \in E,\ f(x) \geq \beta,\ U_{1/m}(x) \subseteq G_x\}.$$

Then there is some $m \geq 1$ such that $\mu^* A_m \geq \mu E - \epsilon$, $\mu^* B_m \geq \mu E - \epsilon$. Let $\delta' \in \Delta$ be such that

$$\delta' \subseteq \delta \cap \{(x,C) : x \in C \subseteq U_{1/3m}(x)\}.$$

Let $\mathcal{R}' \in \mathfrak{R}$ be such that $\mathcal{R}' \subseteq \mathcal{R}$ and $\mu^*(R \cap E) \leq \epsilon$ for every $R \in \mathcal{R}'$.

Let $\boldsymbol{t}$ be any δ'-fine $\mathcal{R}'$-filling member of T. Enumerate $\boldsymbol{t}$ as $\langle (x_i, C_i)\rangle_{i<n}$. Set

$$J = \{i : i < n,\ C_i \cap A_m \text{ is negligible}\}, \quad J' = \{i : i < n,\ C_i \cap B_m \text{ is negligible}\}.$$

Then

$$\mu(E \cap \textstyle\bigcup_{i\in J} C_i) \leq \mu_*(E \setminus A_m) = \mu E - \mu^*(E \cap A_m) \leq \epsilon,$$

and similarly $\mu(E \cap \bigcup_{i\in J'} C_i) \leq \epsilon$. Also, because $\bigcup_{i<m} C_i = W_{\boldsymbol{t}}$ belongs to $\mathcal{R}'$, $\mu(E \setminus \bigcup_{i<m} C_i) \leq \epsilon$. So, setting $K = n \setminus (J \cup J')$, $\sum_{i\in K} \mu C_i \geq \mu E - 3\epsilon$.

For $i \in K$, $\mu^*(C_i \cap A_m) > 0$, while $\{x : x \in C_i,\ (x,C_i) \notin Q\}$ is negligible, so we can find $x_i' \in C_i \cap A_m$ such that $(x_i', C_i) \in Q$; similarly, there is an $x_i'' \in C_i \cap B_m$ such that $(x_i'', C_i) \in Q$. For other $i < n$, set $x_i' = x_i'' = x_i$. By conditions (ii)-(iii) of this proposition, $\boldsymbol{s} = \{(x_i', C_i) : i < n\}$ and $\boldsymbol{s}' = \{(x_i'', C_i) : i < n\}$ belong to T. Of course they are $\mathcal{R}'$-filling, therefore $\mathcal{R}$-filling, because $\boldsymbol{t}$ is. We also see that, because $(x_i, C_i) \in \delta'$, the diameter of C_i is at most $\frac{2}{3m}$ for each $i < n$, so that $C_i \subseteq G_{x_i'}$ and $(x_i', C_i) \in \delta$ for each $i \in K$. But since surely $(x_i, C_i) \in \delta' \subseteq \delta$ for $i \in n \setminus K$, this means that $\boldsymbol{s}$ is δ-fine. Similarly, $\boldsymbol{s}'$ is δ-fine.

We must therefore have

$$|S_{\boldsymbol{s}'}(f,\mu) - S_{\boldsymbol{s}}(f,\mu)| \leq |S_{\boldsymbol{s}'}(f,\mu) - I_\mu(f)| + |S_{\boldsymbol{s}}(f,\mu) - I_\mu(f)| \leq 2\epsilon.$$

But

$$S_{\boldsymbol{s}'}(f,\mu) - S_{\boldsymbol{s}}(f,\mu) = \sum_{i\in K}(f(x_i'') - f(x_i'))\mu C_i$$
$$\geq (\beta-\alpha)\sum_{i\in K}\mu C_i \geq (\beta-\alpha)(\mu E - 3\epsilon) > 2\epsilon$$

by the choice of ϵ. **X**

So we have the result.

482F Proposition Let X, Σ, μ, $\mathfrak{T}$, T, Δ and $\mathfrak{R}$ be such that

(i) (X,Σ,μ) is a measure space;

(ii) $\mathfrak{T}$ is a topology on X such that μ is inner regular with respect to the closed sets and outer regular with respect to the open sets;

(iii) $T \subseteq [X\times\Sigma]^{<\omega}$ is a set of tagged partitions such that $C\cap C'$ is empty whenever (x,C), (x',C') are distinct members of any $\boldsymbol{t}\in T$;

(iv) Δ is a set of gauges on X containing every neighbourhood gauge on X;

(v) $\mathfrak{R}$ is a collection of families of subsets of X such that whenever $\mu E<\infty$ and $\epsilon>0$ there is an $\mathcal{R}\in\mathfrak{R}$ such that $\mu^*(E\cap R)\leq\epsilon$ for every $R\in\mathcal{R}$;

(vi) T is compatible with Δ and $\mathfrak{R}$.

Then $I_\mu(f) = \lim_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\mathfrak{R})} S_{\boldsymbol{t}}(f,\mu)$ is defined and equal to $\int f d\mu$ for every μ-integrable function $f: X\to\mathbb{R}$.

proof (a) It is worth noting straight away that we can replace (X,Σ,μ) by its completion $(X,\hat\Sigma,\hat\mu)$. **P** We need to check that $\hat\mu$ is inner and outer regular. But inner regularity is 412Ha, and outer regularity is equally elementary: if $\hat\mu E<\gamma$, there is an $E'\in\Sigma$ such that $E\subseteq E'$ and $\mu E' = \hat\mu E$ (212C), and now there is an open set $G\in\Sigma$ such that $E'\subseteq G$ and $\mu G\leq\gamma$, so that $E\subseteq G$ and $\hat\mu G\leq\gamma$. Since we are not changing T or Δ or $\mathfrak{R}$, $I_{\hat\mu}(f) = I_\mu(f)$ if either is defined; while also $\int f d\mu = \int f d\hat\mu$ if either is defined, by 212Fb. **Q**

So let us suppose that μ is actually complete.

(b) In this case, f is measurable. Suppose to begin with that it is non-negative. Let $\epsilon>0$. For $m\in\mathbb{Z}$, set $E_m = \{x : x\in X,\ (1+\epsilon)^m\leq f(x)<(1+\epsilon)^{m+1}\}$. Then E_m is measurable and has finite measure, so there is a measurable open set $G_m\supseteq E_m$ such that $(1+\epsilon)^{m+1}\mu(G_m\setminus E_m)\leq 2^{-|m|}\epsilon$.

Take a set H_0 of finite measure and $\eta_0>0$ such that $\int_E f d\mu\leq\epsilon$ whenever $E\in\Sigma$ and $\mu(E\cap H_0)\leq 2\eta_0$ (225A); replacing H_0 by $\{x : x\in H_0,\ f(x)>0\}$ if necessary, we may suppose that $H_0\subseteq\bigcup_{m\in\mathbb{Z}} E_m$. Let $F\subseteq H_0$ be a closed set such that $\mu(H_0\setminus F)\leq\eta_0$.

Define $\langle V_x\rangle_{x\in X}$ by setting $V_x = G_m$ if $m\in\mathbb{Z}$ and $x\in E_m$, $V_x = X\setminus F$ if $f(x)=0$. Let $\delta\in\Delta$ be the corresponding neighbourhood gauge $\{(x,C) : x\in X,\ C\subseteq V_x\}$. Let $\mathcal{R}\in\mathfrak{R}$ be such that $\mu^*(R\cap H_0)\leq\eta_0$ for every $R\in\mathcal{R}$.

Suppose that $\boldsymbol{t}$ is any δ-fine $\mathcal{R}$-filling member of T. Enumerate $\boldsymbol{t}$ as $\langle(x_i,C_i)\rangle_{i<n}$. For each $m\in\mathbb{Z}$, set $J_m = \{i : i<n,\ x_i\in E_m\}$. Then $C_i\subseteq V_{x_i}\subseteq G_m$ for every $i\in J_m$, so

$$S_{\boldsymbol{t}}(f,\mu) = \sum_{i<n} f(x_i)\mu C_i = \sum_{m\in\mathbb{Z}}\sum_{i\in J_m} f(x_i)\mu C_i \leq \sum_{m\in\mathbb{Z}}(1+\epsilon)^{m+1}\mu G_m$$
$$\leq (1+\epsilon)\sum_{m\in\mathbb{Z}}(1+\epsilon)^m\mu E_m + \sum_{m\in\mathbb{Z}}(1+\epsilon)^{m+1}\mu(G_m\setminus E_m)$$
$$\leq (1+\epsilon)\int f d\mu + \sum_{m\in\mathbb{Z}} 2^{-|m|}\epsilon = (1+\epsilon)\int f d\mu + 3\epsilon.$$

On the other hand, set $F' = F\cap\bigcup_{i<n} C_i$. Because $\bigcup_{i<n} C_i\in\mathcal{R}$, $\mu(H_0\setminus F')\leq 2\eta_0$, and

$$S_{\boldsymbol{t}}(f,\mu) \geq \sum_{m\in\mathbb{Z}}\sum_{i\in J_m} f(x_i)\mu(C_i\cap F)$$
$$\geq (1+\epsilon)^{-1}\sum_{m\in\mathbb{Z}}\sum_{i\in J_m}(1+\epsilon)^{m+1}\mu(C_i\cap F)$$
$$\geq (1+\epsilon)^{-1}\int_{F'} f d\mu \geq (1+\epsilon)^{-1}(\int f d\mu - \epsilon).$$

What this means is that

$$\{\boldsymbol{t} : (1+\epsilon)^{-1}(\int f d\mu - \epsilon) \leq S_{\boldsymbol{t}}(f,\nu) \leq (1+\epsilon)\int f d\mu + 3\epsilon\}$$

belongs to $\mathcal{F}(T,\Delta,\Re)$, for any $\epsilon > 0$. So $\lim_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\Re)} S_{\boldsymbol{t}}(f,\mu)$ is defined and equal to $\int f d\mu$.

(c) In general, f is expressible as $f^+ - f^-$ where f^+ and f^- are non-negative integrable functions, so

$$I_\nu(f) = I_\nu(f^+) - I_\nu(f^-) = \int f d\mu$$

by 481Ca.

482G Proposition Let X, $\mathfrak{T}$, $\mathcal{C}$, ν, T, Δ and $\Re$ be such that

(i) $(X,T,\Delta,\Re)$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$;

(ii) $\mathfrak{T}$ is a topology on X, and Δ is the set of neighbourhood gauges on X;

(iii) $\nu : \mathcal{C} \to \mathbb{R}$ is a functional such that

(α) ν is additive in the sense that $\nu C = \sum_{i=0}^n \nu C_i$ whenever $C_0,\dots,C_n \in \mathcal{C}$ are disjoint and $\bigcup_{i\leq n} C_i = C$ belongs to $\mathcal{C}$,

(β) whenever $C \in \mathcal{C}$ and $\epsilon > 0$, there are closed sets $F \subseteq C$, $F' \subseteq X \setminus C$ such that

$$\sup\{\textstyle\sum_{i=0}^n |\nu C_i| : C_0,\dots,C_n \in \mathcal{C} \text{ are disjoint, } \bigcup_{i\leq n} C_i \cap (F \cup F') = \emptyset\} \leq \epsilon;$$

(iv) whenever $E \in \mathcal{C}$ there is a $\delta_0 \in \Delta$ such that whenever $\{(x,C)\} \in T \cap \delta_0$ and $x \in \partial E$ there is a partition $C_0,\dots,C_n$ of C such that, for each $i \leq n$, $\{(x,C_i)\} \in T$ and either $C_i \subseteq E$ or $C_i \cap E = \emptyset$;

(v) whenever $C \in \mathcal{C}$ and $\mathcal{R} \in \Re$, there is an $\mathcal{R}' \in \Re$ such that $R \cap C \in \mathcal{R}$ for every $R \in \mathcal{R}'$.

Let $f : X \to \mathbb{R}$ be a function such that $I_\nu(f) = \lim_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\Re)} S_{\boldsymbol{t}}(f,\nu)$ is defined. Let $\mathcal{E}$ be the algebra of subsets of X generated by $\mathcal{C}$, and $F : \mathcal{E} \to \mathbb{R}$ the Saks-Henstock indefinite integral of f. Then $I_\nu(f \times \chi H)$ is defined and equal to $F(H)$ for every $H \in \mathcal{E}$.

proof (a) Because both F and I_ν are additive, and $F(X) = I_\nu(f)$ (482B), and either H or its complement is a finite disjoint union of members of $\mathcal{C}$ (481Hd), it is enough to consider the case in which $H \in \mathcal{C}$. Let $\epsilon > 0$. Let $\delta_1 \in \Delta$ and $\mathcal{R}_1 \in \Re$ be such that $\sum_{(x,C)\in\boldsymbol{t}} |F(C) - f(x)\nu C| \leq \epsilon$ for every δ_1-fine $\boldsymbol{t} \in T$, and $|F(E)| \leq \epsilon$ for every $E \in \mathcal{E} \cap \mathcal{R}_1$. Let $\delta_0 \in \Delta$ be such that whenever $\{(x,C)\} \in T \cap \delta_0$ and $x \in \partial H$ there is a partition $C_0,\dots,C_n$ of C such that, for each $i \leq n$, $\{(x,C_i)\} \in T$ and either $C_i \subseteq H$ or $C_i \cap H = \emptyset$.

For each $n \in \mathbb{N}$ let $F_n \subseteq H$, $F_n' \subseteq X \setminus H$ be such that

$$\sup\{\textstyle\sum_{i=0}^n |\nu C_i| : C_0,\dots,C_n \in \mathcal{C} \text{ are disjoint, } \bigcup_{i\leq n} C_i \cap (F \cup F') = \emptyset\} \leq \frac{2^{-n}\epsilon}{n+1}.$$

Define $\langle V_x\rangle_{x\in X}$ by setting

$$\begin{aligned} V_x &= \operatorname{int} H \text{ if } x \in \operatorname{int} H,\\ &= X \setminus \overline{H} \text{ if } x \in X \setminus \overline{H},\\ &= X \setminus F_n \text{ if } x \in \overline{H} \setminus H \text{ and } n \leq |f(x)| < n+1,\\ &= X \setminus F_n' \text{ if } x \in H \setminus \operatorname{int} H \text{ and } n \leq |f(x)| < n+1, \end{aligned}$$

so that each V_x is an open set containing x. Let δ_2 be the neighbourhood gauge corresponding to the family $\langle V_x\rangle_{x\in X}$, and set $\delta = \delta_0 \cap \delta_1 \cap \delta_2 \in \Delta$. Let $\mathcal{R} \in \Re$ be such that $R \cap H \in \mathcal{R}_1$ whenever $R \in \mathcal{R}$.

(b) Let T' be the set of those $\boldsymbol{t} \in T$ such that, for each $(x,C) \in \boldsymbol{t}$, either $C \subseteq H$ or $C \cap H = \emptyset$. The key to the proof is the following fact: if $\boldsymbol{t} \in T$ is δ-fine, then there is a δ-fine $\boldsymbol{s} \in T'$ such that $W_{\boldsymbol{s}} = W_{\boldsymbol{t}}$ and $S_{\boldsymbol{s}}(g,\nu) = S_{\boldsymbol{t}}(g,\nu)$ for every $g : X \to \mathbb{R}$. **P** Enumerate $\boldsymbol{t}$ as $\langle (x_i,C_i)\rangle_{i<n}$. For each $i < n$ define $\boldsymbol{s}_i \in T$ as follows. If $x_i \notin \partial H$, then take $\boldsymbol{s}_i = \{(x_i,C_i)\}$. Observe that because $C_i \subseteq V_{x_i}$, we either have $x_i \in \operatorname{int} H$ and $C_i \subseteq H$ or $x_i \notin \overline{H}$ and $C_i \cap H = \emptyset$. If $x_i \in \partial H$, then, because $(x_i,C_i) \in \delta_0$, we can find a finite partition $\mathcal{D}_i$ of C_i into sets such that, for each $D \in \mathcal{D}_i$, $\{(x_i,D)\} \in T$ and D is either included in H or disjoint from it; set $\boldsymbol{s}_i = \{(x_i,D) : D \in \mathcal{D}_i\}$. Because δ is a neighbourhood gauge, $(x_i,D) \in \delta$ for every $D \in \mathcal{D}_i$. Now take $\boldsymbol{s} = \bigcup_{i<n} \boldsymbol{s}_i$; it is easy to see that this works, because ν is additive, so $\nu C_i = \sum_{D\in\mathcal{D}_i} \nu D$ when $x_i \in \partial H$. **Q**

(c) Now $|S_{\boldsymbol{t}}(f\times\chi H,\nu)-F(H)|\le 4\epsilon$ for every δ-fine $\mathcal{R}$-filling $\boldsymbol{t}\in T$. **P** By (b), there is a δ-fine $\mathcal{R}$-filling $\boldsymbol{s}\in T'$ such that $S_{\boldsymbol{t}}(f\times\chi H,\nu)=S_{\boldsymbol{s}}(f\times\chi H,\nu)$. Discarding any terms of the form $(x,\emptyset)$, we may suppose that $C\neq\emptyset$ whenever $(x,C)\in\boldsymbol{s}$. Consider

$$\boldsymbol{u}=\{(x,C):(x,C)\in\boldsymbol{s},\ C\subseteq H\},\quad \boldsymbol{v}=\{(x,C):(x,C)\in\boldsymbol{s},\ x\in H\}.$$

Then $W_{\boldsymbol{u}}=H\cap W_{\boldsymbol{s}}$, so we have

$$\begin{aligned}S_{\boldsymbol{s}}(f\times\chi H,\nu)&=S_{\boldsymbol{v}}(f,\nu),\\ |F(H)-S_{\boldsymbol{u}}(f,\nu)|&\le|F(H)-F(W_{\boldsymbol{u}})|+\sum_{(x,C)\in\boldsymbol{u}}|F(C)-f(x)\nu C|\\ &\le|F(H\setminus W_{\boldsymbol{s}})|+\epsilon\end{aligned}$$

(because $\boldsymbol{u}$ is δ-fine)

$$\le 2\epsilon$$

because $X\setminus W_{\boldsymbol{s}}\in\mathcal{R}$, so $H\setminus W_{\boldsymbol{s}}\in\mathcal{R}_1$.

Enumerate $\boldsymbol{s}$ as $\langle(x_i,C_i)\rangle_{i<n}$, so that

$$S_{\boldsymbol{u}}(f,\nu)=\textstyle\sum_{i\in J}f(x_i)\nu C_i,\quad S_{\boldsymbol{v}}(f\times\chi H,\nu)=\sum_{i\in K}f(x_i)\nu C_i,$$

where $J=\{i:i<n,\ C_i\subseteq H\}$, $K=\{i:i<n,\ x_i\in H\}$. For $m\in\mathbb{N}$, set $J_m=\{i:i\in J\setminus K,\ m\le|f(x)|<m+1\}$, $K_m=\{i:i\in K\setminus J,\ m\le|f(x)|<m+1\}$. If $i\in J_m$, then $x_i\notin H$ but $\emptyset\neq C_i\subseteq H$, so $V_{x_i}\cap H\neq\emptyset$ and $x_i\in\overline{H}\setminus H$; which implies that $V_{x_i}=X\setminus F_m$ and $C_i\subseteq H\setminus F_m$. Similarly, if $i\in K_m$, then $x_i\in H$ and $C_i\cap H=\emptyset$, so $x_i\in H\setminus\operatorname{int}H$ and $C_i\subseteq(X\setminus H)\setminus F'_m$. Now, for each i, $\langle C_i\rangle_{i\in J_m\cup K_m}$ is a disjoint family in $\mathcal{C}$ with union included in $X\subseteq(F_m\cup F'_m)$, so

$$\textstyle\sum_{i\in J_m\cup K_m}|\nu C_i|\le\frac{2^{-m}\epsilon}{m+1}.$$

So we have

$$\begin{aligned}|S_{\boldsymbol{u}}(f,\nu)-S_{\boldsymbol{v}}(f,\nu)|&=|\sum_{i\in J}f(x_i)\nu C_i-\sum_{i\in K}f(x_i)\nu C_i|\le\sum_{i\in J\triangle K}|f(x_i)\nu C_i|\\ &\le\sum_{m=0}^{\infty}\big(\sum_{i\in J_m}|f(x_i)\nu C_i|+\sum_{i\in K_m}|f(x_i)\nu C_i|\big)\\ &\le\sum_{m=0}^{\infty}2^{-m}\epsilon=2\epsilon.\end{aligned}$$

Putting these together,

$$\begin{aligned}|S_{\boldsymbol{t}}(f\times\chi H,\nu)-F(H)|&\le|S_{\boldsymbol{v}}(f,\nu)-S_{\boldsymbol{u}}(f,\nu)|+|S_{\boldsymbol{u}}(f,\nu)-F(H)|\\ &\le 2\epsilon+2\epsilon=4\epsilon.\ \textbf{Q}\end{aligned}$$

(d) As ϵ is arbitrary, $I_\nu(f\times\chi H)$ is defined and equal to $F(H)$, as claimed.

482H Proposition Suppose that X, $\mathfrak{T}$, $\mathcal{C}$, ν, T, Δ and $\mathfrak{R}$ satisfy the conditions (i)-(v) of 482G, and that $f:X\to\mathbb{R}$, $\langle H_n\rangle_{n\in\mathbb{N}}$, H and γ are such that

(vi) $\langle H_n\rangle_{n\in\mathbb{N}}$ is a sequence of open subsets of X with union H,

(vii) $I_\nu(f\times\chi H_n)$ is defined for every $n\in\mathbb{N}$,

(viii) $\lim_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\mathfrak{R})}I_\nu(f\times\chi W_{\boldsymbol{t}\restriction H})$ is defined and equal to γ,

where $\boldsymbol{t}\restriction H=\{(x,C):(x,C)\in\boldsymbol{t},\ x\in H\}$ for $\boldsymbol{t}\in T$. Then $I_\nu(f\times\chi H)$ is defined and equal to γ.

proof Let $\epsilon>0$. For each $n\in\mathbb{N}$, let F_n be the Saks-Henstock indefinite integral of $f\times\chi H_n$. Let $\delta_n\in\Delta$ be such that

$$\begin{aligned}2^{-n}\epsilon &\geq \sum_{(x,C)\in\boldsymbol{s}} |F_n(C) - (f\times\chi H_n)(x)\nu C|\\ &\geq |F_n(W_{\boldsymbol{s}}) - S_{\boldsymbol{s}}(f\times\chi H_n,\nu)|\end{aligned}$$

whenever $\boldsymbol{s}\in T$ is δ_n-fine. Set

$$\begin{aligned}\tilde\delta = \{(x,A) &: x\in X\setminus H,\ A\subseteq X\}\\ &\cup \bigcup_{n\in\mathbb{N}} \{(x,A) : x\in H_n\setminus\bigcup_{i<n} H_i,\ A\subseteq H_n,\ (x,A)\in\delta_n\},\end{aligned}$$

so that $\tilde\delta\in\Delta$. Note that if $x\in H$ and $C\in\mathcal{C}$ and $(x,C)\in\tilde\delta$, then there is some $n\in\mathbb{N}$ such that $x\in H_n$ and $C\subseteq H_n$, so that

$$I_\nu(f\times\chi C) = I_\nu((f\times\chi H_n)\times\chi C) = F_n(C)$$

is defined, by 482G; this means that $I_\nu(f\times\chi W_{\boldsymbol{t}\restriction H})$ will be defined for every $\tilde\delta$-fine $\boldsymbol{t}\in T$. Let $\delta\in\Delta$, $\mathcal{R}\in\mathfrak{R}$ be such that $|\gamma - I_\nu(f\times\chi W_{\boldsymbol{t}\restriction H})|\leq\epsilon$ whenever $\boldsymbol{t}\in T$ is δ-fine and $\mathcal{R}$-filling.

Let $\boldsymbol{t}\in T$ be $(\delta\cap\tilde\delta)$-fine and $\mathcal{R}$-filling. For $n\in\mathbb{N}$, set $\boldsymbol{t}_n = \{(x,C) : (x,C)\in\boldsymbol{t},\ x\in H_n\setminus\bigcup_{i<n}H_i\}$. Then $\boldsymbol{t}\restriction H = \bigcup_{n\in\mathbb{N}}\boldsymbol{t}_n$, and $\boldsymbol{t}_n$ is δ_n-fine and $W_{\boldsymbol{t}_n}\subseteq H_n$ for every n. So

$$\begin{aligned}|\gamma - S_{\boldsymbol{t}}(f\times\chi H,\nu)| &= |\gamma - \sum_{n=0}^\infty S_{\boldsymbol{t}_n}(f\times\chi H_n,\nu)|\\ &\leq |\gamma - I_\nu(f\times\chi W_{\boldsymbol{t}\restriction H})| + \sum_{n=0}^\infty |I_\nu(f\times\chi W_{\boldsymbol{t}_n}) - S_{\boldsymbol{t}_n}(f\times\chi H_n,\nu)|\end{aligned}$$

(note that $\boldsymbol{t}_n=\emptyset$ for all but finitely many n, so that $I_\nu(f\times\chi W_{\boldsymbol{t}\restriction H}) = \sum_{n=0}^\infty I_\nu(f\times\chi W_{\boldsymbol{t}_n})$)

$$\leq \epsilon + \sum_{n=0}^\infty |I_\nu(f\times\chi H_n\times\chi W_{\boldsymbol{t}_n}) - S_{\boldsymbol{t}_n}(f\times\chi H_n,\nu)|$$

(because $\boldsymbol{t}$ is δ-fine and $\mathcal{R}$-filling, while $W_{\boldsymbol{t}_n}\subseteq H_n$ for each n)

$$= \epsilon + \sum_{n=0}^\infty |F_n(W_{\boldsymbol{t}_n}) - S_{\boldsymbol{t}_n}(f\times\chi H_n,\nu)|$$

(by 482G)

$$\leq \epsilon + \sum_{n=0}^\infty 2^{-n}\epsilon$$

(because every $\boldsymbol{t}_n$ is δ_n-fine)

$$= 3\epsilon.$$

As ϵ is arbitrary, $\gamma = I_\nu(f\times\chi H)$, as claimed.

Remark For applications of this result see 483Bd and 483N.

482I Definitions (a) Let X be a set and $\Delta\subseteq\mathcal{P}(X\times\mathcal{P}X)$ a family of gauges on X. I will say that Δ is **countably full** if whenever $\langle\delta_n\rangle_{n\in\mathbb{N}}$ is a sequence in Δ, and $\phi : X\to\mathbb{N}$ is any function, then there is a $\delta\in\Delta$ such that $(x,C)\in\delta_{\phi(x)}$ whenever $(x,C)\in\delta$. I will say that Δ is **full** if whenever $\langle\delta_x\rangle_{x\in X}$ is a family in Δ, then there is a $\delta\in\Delta$ such that $(x,C)\in\delta_x$ whenever $(x,C)\in\delta$.

Of course a full set of gauges is countably full. Observe that if $(X,\mathfrak{T})$ is any topological space, the set of all neighbourhood gauges on X is full.

(b) Let X be a set, $\mathcal{C}$ a family of subsets of X, $T\subseteq[X\times\mathcal{C}]^{<\omega}$ a family of tagged partitions, $\nu:\mathcal{C}\to[0,\infty[$ a function, and Δ a family of gauges on X. I will say that ν is **moderated** (with respect to T and Δ) if there are a $\delta\in\Delta$ and a function $h:X\to]0,\infty[$ such that $S_{\boldsymbol{t}}(h,\nu)\leq 1$ for every δ-fine $\boldsymbol{t}\in T$.

482J Integrating a derivative As will appear in the next two sections, the real strength of gauge integrals is in their power to integrate derivatives. I give an elementary general expression of this fact. In the formulae below, we can think of f as a 'derivative' of F if $\nu = \theta$ is strictly positive and additive and we rephrase condition (iii) as

$$\text{`}\lim_{C \to \mathcal{G}_x} \tfrac{F(C)}{\nu C} = f(x)\text{'},$$

where $\mathcal{G}_x$ is the filter on $\mathcal{C}$ generated by the sets $\{C : (x, C) \in \delta\}$ as δ runs over Δ.

Theorem Let X, $\mathcal{C} \subseteq \mathcal{P}X$, $\Delta \subseteq \mathcal{P}(X \times \mathcal{P}X)$, $\mathfrak{R} \subseteq \mathcal{P}\mathcal{P}X$, $T \subseteq [X \times \mathcal{C}]^{<\omega}$, $f : X \to \mathbb{R}$, $\nu : \mathcal{C} \to \mathbb{R}$, $F : \mathcal{C} \to \mathbb{R}$, $\theta : \mathcal{C} \to [0, 1]$ and $\gamma \in \mathbb{R}$ be such that

(i) T is a straightforward set of tagged partitions which is compatible with Δ and $\mathfrak{R}$,

(ii) Δ is a full set of gauges on X,

(iii) for every $x \in X$ and $\epsilon > 0$ there is a $\delta \in \Delta$ such that $|f(x)\nu C - F(C)| \leq \epsilon\theta C$ whenever $(x, C) \in \delta$,

(iv) $\sum_{i=0}^{n} \theta C_i \leq 1$ whenever $C_0, \ldots, C_n \in \mathcal{C}$ are disjoint,

(v) for every $\epsilon > 0$ there is an $\mathcal{R} \in \mathfrak{R}$ such that $|\gamma - \sum_{C \in \mathcal{C}_0} F(C)| \leq \epsilon$ whenever $\mathcal{C}_0 \subseteq \mathcal{C}$ is a finite disjoint set and $X \setminus \bigcup \mathcal{C}_0 \in \mathcal{R}$.

Then $I_\nu(f) = \lim_{\boldsymbol{t} \to \mathcal{F}(T, \Delta, \mathfrak{R})} S_{\boldsymbol{t}}(f, \nu)$ is defined and equal to γ.

proof Let $\epsilon > 0$. For each $x \in X$ let $\delta_x \in \Delta$ be such that $|f(x)\nu C - F(C)| \leq \epsilon\theta C$ whenever $(x, C) \in \delta_x$. Because Δ is full, there is a $\delta \in \Delta$ such that $(x, C) \in \delta_x$ whenever $(x, C) \in \delta$. Let $\mathcal{R} \in \mathfrak{R}$ be as in (v). If $\boldsymbol{t} \in T$ is δ-fine and $\mathcal{R}$-filling, then

$$\begin{aligned} |S_{\boldsymbol{t}}(f, \nu) - \gamma| &\leq \sum_{(x,C) \in \boldsymbol{t}} |f(x)\nu C - F(C)| + |\gamma - \sum_{(x,C) \in \boldsymbol{t}} F(C)| \\ &\leq \sum_{(x,C) \in \boldsymbol{t}} \epsilon\theta C + \epsilon \end{aligned}$$

(because $(x, C) \in \delta_x$ whenever $(x, C) \in \boldsymbol{t}$, while $X \setminus \bigcup_{(x,C) \in \boldsymbol{t}} C \in \mathcal{R}$)

$$\leq 2\epsilon$$

by condition (ii). As ϵ is arbitrary, we have the result.

482K B.Levi's Theorem Let $(X, T, \Delta, \mathfrak{R})$ be a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$, such that Δ is countably full. Let $\nu : \mathcal{E} \to \mathbb{R}$ be a non-negative finitely additive functional, where $\mathcal{E}$ is a ring of subsets of X including $\mathcal{C}$, which is moderated with respect to T and Δ.

Let $\langle f_n \rangle_{n \in \mathbb{N}}$ be a non-decreasing sequence of functions from X to $\mathbb{R}$ with supremum $f : X \to \mathbb{R}$. If $\gamma = \lim_{n \to \infty} I_\nu(f_n)$ is defined in $\mathbb{R}$, then $I_\nu(f)$ is defined and equal to γ.

proof As in the proof of 123A, we may, replacing $\langle f_n \rangle_{n \in \mathbb{N}}$ by $\langle f_n - f_0 \rangle_{n \in \mathbb{N}}$ if necessary, suppose that $f_n(x) \geq 0$ for every $n \in \mathbb{N}$, $x \in X$.

(a) Take $\epsilon > 0$. Then there is a $\delta \in \Delta$ such that $S_{\boldsymbol{t}}(f, \nu) \leq \gamma + 5\epsilon$ for every δ-fine $\boldsymbol{t} \in T$.

P Fix a strictly positive function $h : X \to]0, \infty[$ and a $\tilde{\delta} \in \Delta$ such that $S_{\boldsymbol{t}}(h, \nu) \leq 1$ for every $\tilde{\delta}$-fine $\boldsymbol{t} \in T$. Let $\epsilon > 0$. For each $n \in \mathbb{N}$ choose $\delta_n \in \Delta$, $\mathcal{R}_n \in \mathfrak{R}$ such that $|I_\nu(f_n) - S_{\boldsymbol{t}}(f, \nu)| \leq 2^{-n}\epsilon$ for every δ_n-fine $\mathcal{R}_n$-filling $\boldsymbol{t} \in T$. For each $x \in X$, take $r_x \in \mathbb{N}$ such that $f(x) \leq f_{r_x}(x) + \epsilon h(x)$. Let $\delta \in \Delta$ be such that $(x, C) \in \tilde{\delta} \cap \delta_{r_x}$ for every $(x, C) \in \delta$.

Suppose that $\boldsymbol{t} \in T$ is δ-fine. Enumerate $\boldsymbol{t}$ as $\langle (x_i, C_i) \rangle_{i < n}$. Let $k \in \mathbb{N}$ be so large that $S_{\boldsymbol{t}}(f, \nu) \leq S_{\boldsymbol{t}}(f_k, \nu) + \epsilon$ and $r_{x_i} \leq k$ for every $i < n$. For $m \leq k$, set $J_m = \{i : i < n, r_{x_i} = m\}$. For each $i \in J_m$, $(x_i, C_i) \in \delta_m$. By 482A(c-ii), there is a δ_k-fine $\boldsymbol{s}_m \in T$ such that $W_{\boldsymbol{s}_m} \subseteq \bigcup_{i \in J_m} C_i$ and $|S_{\boldsymbol{s}_m}(f_m, \nu) - \sum_{i \in J_m} f_m(x_i)\nu C_i| \leq 2^{-m}\epsilon$.

Set $\boldsymbol{s} = \bigcup_{m \leq k} \boldsymbol{s}_m$, so that $\boldsymbol{s}$ is a δ_k-fine member of T and

$$\begin{aligned} \sum_{m=0}^{k} \sum_{i \in J_m} f_m(x_i)\nu C_i &\leq \sum_{m=0}^{k} S_{\boldsymbol{s}_m}(f_m, \nu) + 2^{-m}\epsilon \leq \sum_{m=0}^{k} S_{\boldsymbol{s}_m}(f_k, \nu) + 2^{-m}\epsilon \\ &\leq S_{\boldsymbol{s}}(f_k, \nu) + 2\epsilon \leq I_\nu(f_k) + 3\epsilon \end{aligned}$$

(because $\boldsymbol{s}$ extends to a δ_k-fine $\mathcal{R}_k$-filling member of T, by 482Ab)

$$\leq \gamma + 3\epsilon.$$

Now $\boldsymbol{t}$ is $\tilde{\delta}$-fine, so $S_{\boldsymbol{t}}(h,\nu) \leq 1$. Accordingly

$$\begin{aligned} S_{\boldsymbol{t}}(f) &= \sum_{i<n} f(x_i)\nu C_i = \sum_{m=0}^{k} \sum_{i\in J_m} f(x_i)\nu C_i \\ &\leq \sum_{m=0}^{k} \sum_{i\in J_m} (f_m(x_i) + \epsilon h(x_i))\nu C_i \leq \gamma + 3\epsilon + \epsilon S_{\boldsymbol{t}}(h,\nu) \leq \gamma + 4\epsilon, \end{aligned}$$

as required. **Q**

As ϵ is arbitrary, $\limsup_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\Re)} S_{\boldsymbol{t}}(f,\nu)$ is at most γ.

(b) On the other hand, given $\epsilon > 0$, there is an $n \in \mathbb{N}$ such that $I_\nu(f) \geq \gamma - \epsilon$. So taking $\delta_n \in \Delta$, $\mathcal{R}_n \in \Re$ as in (a) above,

$$S_{\boldsymbol{t}}(f,\nu) \geq S_{\boldsymbol{t}}(f_n,\nu) \geq I_\nu(f_n) - \epsilon \geq \gamma - 2\epsilon$$

for every δ_n-fine $\mathcal{R}_n$-filling $\boldsymbol{t} \in T$. So $\liminf_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\Re)} S_{\boldsymbol{t}}(f,\nu)$ is at least γ, and $I_\nu(f) = \gamma$.

482L Lemma Let X be a set, $\mathcal{C}$ a family of subsets of X, Δ a countably full downwards-directed set of gauges on X, $\Re \subseteq \mathcal{PP}X$ a downwards-directed collection of residual families, and $T \subseteq [X \times \mathcal{C}]^{<\omega}$ a straightforward set of tagged partitions of X compatible with Δ and $\Re$. Suppose further that whenever $\delta \in \Delta$, $\mathcal{R} \in \Re$ and $\boldsymbol{t} \in T$ is δ-fine, there is a δ-fine $\mathcal{R}$-filling $\boldsymbol{t}' \in T$ including $\boldsymbol{t}$. If $\nu : \mathcal{C} \to [0,\infty[$ and $f : X \to [0,\infty[$ are such that $I_\nu(f) = 0$, and $g : X \to \mathbb{R}$ is such that $g(x) = 0$ whenever $f(x) = 0$, then $I_\nu(g) = 0$.

proof Let $\epsilon > 0$. For each $n \in \mathbb{N}$, let $\delta_n \in \Delta$, $\mathcal{R}_n \in \Re$ be such that $S_{\boldsymbol{t}}(f,\nu) \leq 2^{-n}\epsilon$ for every δ_n-fine $\mathcal{R}_n$-filling $\boldsymbol{t} \in T$. For $x \in X$, set $\phi(x) = \min\{n : |g(x)| \leq nf(x)\}$; let $\delta \in \Delta$ be such that $(x,C) \in \delta_{\phi(x)}$ whenever $(x,C) \in \delta$.

Let $\boldsymbol{t}$ be any δ-fine member of T. Then $|S_{\boldsymbol{t}}(g,\nu)| \leq 2\epsilon$. **P** Enumerate $\boldsymbol{t}$ as $\langle (x_i,C_i)\rangle_{i<n}$. For each $m \in \mathbb{N}$, set $K_m = \{i : i < n,\ \phi(x_i) = m\}$; then $\{(x_i,C_i) : i \in K_m\}$ is a δ_m-fine member of T, so extends to a δ_m-fine $\mathcal{R}_m$-filling member $\boldsymbol{t}_m$ of T, and

$$\textstyle\sum_{i\in K_m} |g(x_i)\nu C_i| \leq m \sum_{i\in K_m} f(x_i)\nu C_i \leq m S_{\boldsymbol{t}_m}(f,\nu) \leq 2^{-m} m\epsilon.$$

Summing over m,

$$|S_{\boldsymbol{t}}(g,\nu)| \leq \textstyle\sum_{m=0}^{\infty} 2^{-m} m\epsilon = 2\epsilon. \ \textbf{Q}$$

Because T is compatible with Δ and $\mathcal{R}$, this is enough to show that $I_\nu(g)$ is defined and equal to 0.

482M Fubini's theorem Suppose that, for $i = 1$ and $i = 2$, we have X_i, $\mathfrak{T}_i$, T_i, Δ_i, $\mathcal{C}_i$ and ν_i such that

(i) $(X_i,\mathfrak{T}_i)$ is a topological space;

(ii) Δ_i is the set of neighbourhood gauges on X_i;

(iii) $T_i \subseteq [X_i \times \mathcal{C}_i]^{<\omega}$ is a straightforward set of tagged partitions, compatible with Δ_i and $\{\{\emptyset\}\}$;

(iv) $\nu_i : \mathcal{C}_i \to [0,\infty[$ is a function;

(v) ν_1 is moderated with respect to T_1 and Δ_1.

Write X for $X_1 \times X_2$; Δ for the set of neighbourhood gauges on X; $\mathcal{C}$ for $\{C \times D : C \in \mathcal{C}_1,\ D \in \mathcal{C}_2\}$; Q for $\{((x,y), C \times D) : \{(x,C)\} \in T_1,\ \{(y,D)\} \in T_2\}$; T for the straightforward set of tagged partitions generated by Q; and set $\nu(C \times D) = \nu_1 C \cdot \nu_2 D$ for $C \in \mathcal{C}_1$, $D \in \mathcal{C}_2$.

(a) T is compatible with Δ and $\{\{\emptyset\}\}$.

(b) Let I_{ν_1}, I_{ν_2} and I_ν be the gauge integrals defined by these structures as in 481C-481F. Suppose that $f : X \to \mathbb{R}$ is such that $I_\nu(f)$ is defined. Set $f_x(y) = f(x,y)$ for $x \in X_1$, $y \in X_2$. Let $g : X_1 \to \mathbb{R}$ be any function such that $g(x) = I_{\nu_2}(f_x)$ whenever this is defined. Then $I_{\nu_1}(g)$ is defined and equal to $I_\nu(f)$.

proof (a) Let $\delta \in \Delta$; we seek a tagged partition $\boldsymbol{u} \in T$ such that $W_{\boldsymbol{u}} = X$. Let $\langle V_{xy}\rangle_{(x,y)\in X}$ be the family of open sets in X defining δ; choose open sets $G_{xy} \subseteq X_1$, $H_{xy} \subseteq X_2$ such that $(x,y) \in G_{xy} \times H_{xy} \subseteq V_{xy}$

for all $x \in X_1$, $y \in X_2$. For each $x \in X_1$, let δ_x be the neighbourhood gauge on X_2 defined from the family $\langle H_{xy}\rangle_{y\in X_2}$. Then there is a δ_x-fine tagged partition $\boldsymbol{t}_x \in T_2$ such that $W_{\boldsymbol{t}_x} = X_2$. Set $G_x = X_1 \cap \bigcap_{(y,D)\in\boldsymbol{t}_x} G_{xy}$.

The family $\langle G_x\rangle_{x\in X_1}$ defines a neighbourhood gauge δ^* on X_1, so there is a δ^*-fine $\boldsymbol{s} \in T_1$ such that $W_{\boldsymbol{s}} = X_1$. Now consider

$$\boldsymbol{u} = \{((x,y), C\times D) : (x,C) \in \boldsymbol{s},\ (y,D) \in \boldsymbol{t}_x\}.$$

Then it is easy to check (just as in part (b) of the proof of 481O) that $\boldsymbol{u}$ is a δ-fine member of T with $W_{\boldsymbol{u}} = X$.

(b)(i) Let A be $\{x : x \in X_1,\ I_{\nu_2}(f_x) \text{ is defined}\}$. Let $h : X_1 \to \mathbb{R}$ is any function such that $h(x) = 0$ for every $x \in A$. For $x \in X_1$, set

$$h_0(x) = \inf(\{1\} \cup \{\sup_{\boldsymbol{t},\boldsymbol{t}'\in F} S_{\boldsymbol{t}}(f_x,\nu_2) - S_{\boldsymbol{t}'}(f_x,\nu_2) : F \in \mathcal{F}(T_2, \Delta_2, \{\{\emptyset\}\})\}).$$

(Thus $I_{\nu_2}(f_x)$ is defined iff $h_0(x) = 0$.) Then $I_{\nu_1}(h_0) = 0$. **P** Let $\epsilon > 0$. Then there is a $\delta \in \Delta$ such that $S_{\boldsymbol{u}}(f,\nu) - S_{\boldsymbol{u}'}(f,\nu) \le \epsilon$ whenever $\boldsymbol{u}, \boldsymbol{u}' \in T$ are δ-fine and $W_{\boldsymbol{u}} = W_{\boldsymbol{u}'} = X$. Define $\langle V_{xy}\rangle_{(x,y)\in X}$, $\langle G_{xy}\rangle_{(x,y)\in X}$, $\langle H_{xy}\rangle_{(x,y)\in X}$ and $\langle\delta_x\rangle_{x\in X_1}$ from δ as in (a) above. For each $x \in X_1$, we can find δ_x-fine partitions $\boldsymbol{t}_x, \boldsymbol{t}'_x \in T_2$ such that $W_{\boldsymbol{t}_x} = W_{\boldsymbol{t}'_x} = X_2$ and $S_{\boldsymbol{t}_x}(f_x,\nu_2) - S_{\boldsymbol{t}'_x(f_x,\nu_1} \ge \frac{1}{2}h_0(x)$. Set $G_x = X_1 \cap \bigcap_{(y,D)\in\boldsymbol{t}_x\cup\boldsymbol{t}'_x} G_{xy}$.

Let δ^* be the neighbourhood gauge on X_1 defined from $\langle G_x\rangle_{x\in X_1}$. Let $\boldsymbol{s}$ be any δ^*-fine member of T_1 with $W_{\boldsymbol{s}} = X_1$. Set

$$\boldsymbol{u} = \{((x,y), C\times D) : (x,C) \in \boldsymbol{s},\ (y,D) \in \boldsymbol{t}_x\},$$

$$\boldsymbol{u}' = \{((x,y), C\times D) : (x,C) \in \boldsymbol{s},\ (y,D) \in \boldsymbol{t}'_x\},$$

Then $\boldsymbol{u}$ and $\boldsymbol{u}'$ are δ-fine members of T with $W_{\boldsymbol{u}} = W_{\boldsymbol{u}'} = X$, so

$$\begin{aligned}
S_{\boldsymbol{t}}(h_0,\nu_1) &= \sum_{(x,C)\in\boldsymbol{t}} h_0(x)\nu_1(C) \le 2\sum_{(x,C)\in\boldsymbol{t}} (S_{\boldsymbol{t}_x}(f_x,\nu_2) - S_{\boldsymbol{t}'_x}(f_x,\nu_2))\nu_1(C)\\
&= 2\Big(\sum_{\substack{(x,C)\in\boldsymbol{t}\\(y,D)\in\boldsymbol{t}_x}} f(x,y)\nu_1(C)\nu_2(D) - \sum_{\substack{(x,C)\in\boldsymbol{t}\\(y,D)\in\boldsymbol{t}'_x}} f(x,y)\nu_1(C)\nu_2(D)\Big)\\
&= 2\big(S_{\boldsymbol{u}}(f,\nu) - S_{\boldsymbol{u}'}(f,\nu)\big) \le 2\epsilon.
\end{aligned}$$

As ϵ is arbitrary, $I_{\nu_1}(h_0) = 0$. **Q**

By 482L, $I_{\nu_1}(h)$ is also zero.

(ii) Again take any $\epsilon > 0$, and let $\delta \in \Delta$ be such that $|S_{\boldsymbol{u}}(f,\nu) - I_\nu(f)| \le \epsilon$ for every δ-fine $\boldsymbol{u} \in T$ such that $W_{\boldsymbol{u}} = X$. Define $\langle V_{xy}\rangle_{(x,y)\in X}$, $\langle G_{xy}\rangle_{(x,y)\in X}$, $\langle H_{xy}\rangle_{(x,y)\in X}$ and $\langle\delta_x\rangle_{x\in X_1}$ from δ as in (a) and (i) above. Let $\tilde\delta \in \Delta_1$, $\tilde h : X_1 \to]0,\infty[$ be such that $S_{\boldsymbol{s}}(\tilde h,\nu_1) \le 1$ for every $\tilde\delta$-fine $\boldsymbol{s} \in T_1$.

For $x \in A$, let $\boldsymbol{t}_x \in T_2$ be δ_x-fine and such that $W_{\boldsymbol{t}_x} = X_2$ and $|S_{\boldsymbol{t}_x}(f_x,\nu_2) - I_{\nu_2}(f_x)| \le \epsilon\tilde h(x)$; for $x \in X_1 \setminus A$, let $\boldsymbol{t}_x$ be any δ_x-fine member of T_2 such that $W_{\boldsymbol{t}_x} = X_2$. Set $G_x = X_1 \cap \bigcap_{(y,D)\in\boldsymbol{t}_x} G_{xy}$ for every $x \in X_1$. Let δ^* be the neighbourhood gauge on X_1 defined by $\langle G_x\rangle_{x\in X_1}$.

Set $h_1(x) = g(x) - S_{\boldsymbol{t}_x}(f_x,\nu_2)$ for $x \in X_1 \setminus A$, 0 for $x \in A$. Then $I_{\nu_1}(|h_1|) = 0$, by (a). Let $\delta' \in \Delta_1$ be such that $\delta' \subseteq \delta^* \cap \tilde\delta$ and $S_{\boldsymbol{s}}(|h_1|,\nu_1) \le \epsilon$ for every δ'-fine $\boldsymbol{s} \in T_1$ such that $W_{\boldsymbol{s}} = X_1$.

Now suppose that $\boldsymbol{s} \in T_1$ is δ'-fine and that $W_{\boldsymbol{s}} = X_1$. Set

$$\boldsymbol{u} = \{((x,y), C\times D) : (x,C) \in \boldsymbol{s},\ (y,D) \in \boldsymbol{t}_x\},$$

so that $\boldsymbol{u} \in T$ is δ-fine and $W_{\boldsymbol{u}} = X$. Then

$$\begin{aligned}|S_{\boldsymbol{s}}(g,\nu_1) - I_\nu(f)| &\le |S_{\boldsymbol{u}}(f,\nu) - I_\nu(f)| + |S_{\boldsymbol{s}}(g,\nu_1) - S_{\boldsymbol{u}}(f,\nu)| \\ &\le \epsilon + \big|\sum_{(x,C)\in\boldsymbol{s}} \big(g(x) - \sum_{(y,D)\in\boldsymbol{t}_x} f(x,y)\nu_2 D\big)\nu_1 C\big| \\ &= \epsilon + \big|\sum_{(x,C)\in\boldsymbol{s}} \big(g(x) - S_{\boldsymbol{t}_x}(f_x,\nu_2)\big)\nu_1 C\big| \\ &\le \epsilon + \sum_{(x,C)\in\boldsymbol{s}} |h_1(x)|\nu_1 C \\ &\qquad + \sum_{(x,C)\in\boldsymbol{s},x\in A} |g(x) - \sum_{(y,D)\in\boldsymbol{t}_x} f(x,y)\nu_2 D|\nu_1 C \\ &\le 2\epsilon + \sum_{(x,C)\in\boldsymbol{s},x\in A} \epsilon\tilde{h}(x)\nu_1(C) \le 2\epsilon + \epsilon S_{\boldsymbol{s}}(\tilde{h},\nu_1) \le 3\epsilon.\end{aligned}$$

As ϵ is arbitrary, $I_\nu(g)$ is defined and equal to $I_\nu(f)$, as claimed.

482X Basic exercises (a) Let $(X,T,\Delta,\Re)$ be a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$, and $\mathcal{E}$ the algebra of subsets of X generated by $\mathcal{C}$. Write $\mathfrak{I}$ for the set of pairs (f,ν) such that $f : X \to \mathbb{R}$ and $\nu : \mathcal{C} \to \mathbb{R}$ are functions and $I_\nu(f) = \lim_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\Re)} S_{\boldsymbol{t}}(f,\nu)$ is defined; for $(f,\nu) \in \mathfrak{I}$, let $F_{f\nu} : \mathcal{E} \to \mathbb{R}$ be the corresponding Saks-Henstock indefinite integral. Show that $(f,\nu) \mapsto F_{f\nu}$ is bilinear in the sense that

$$F_{f+g,\nu} = F_{f\nu} + F_{g\nu}, \quad F_{\alpha f,\nu} = F_{f,\alpha\nu} = \alpha F_{f\nu}, \quad F_{f,\mu+\nu} = F_{f\mu} + F_{f\nu}$$

whenever (f,ν), (g,ν) and (f,μ) belong to $\mathfrak{I}$ and $\alpha \in \mathbb{R}$.

(b) Let $(X,T,\Delta,\Re)$ be a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$, and $\mathcal{E}$ the algebra of subsets of X generated by $\mathcal{C}$. Let $f : X \to \mathbb{R}$ and $\nu : \mathcal{C} \to [0,\infty[$ be functions such that $I_\nu(f) = \lim_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\Re)} S_{\boldsymbol{t}}(f,\nu)$ is defined, and let $F : \mathcal{E} \to \mathbb{R}$ be the corresponding Saks-Henstock indefinite integral. Show that F is non-negative iff $I_\nu(f^-) = 0$, where $f^-(x) = \max(0, f(x))$ for every $x \in X$.

>(c) Let X be a zero-dimensional compact Hausdorff space, $\mathcal{E}$ the algebra of open-and-closed subsets of X, $Q = \{(x,E) : x \in E \in \mathcal{E}\}$, T the straightforward set of tagged partitions generated by Q, Δ the set of neighbourhood gauges on X and $\nu : \mathcal{E} \to \mathbb{R}$ a non-negative additive functional. Let μ be the corresponding Radon measure on X (416Q) and I_ν the gauge integral defined by $(X,T,\Delta,\{\{\emptyset\}\})$ (cf. 481Xh). Show that, for $f : X \to \mathbb{R}$, $I_\nu(f) = \int f d\mu$ if either is defined in $\mathbb{R}$. (*Hint*: if f is measurable but not μ-integrable, take x_0 such that f is not integrable on any neighbourhood of x_0. Given $\delta \in \Delta$, fix a δ-fine partition containing (x_0,V_0) for some V_0; now replace (x_0,V_0) by refinements $\{(x_0,V_0'),(x_1,V_1),\dots,(x_n,V_n)\}$, where $\sum_{i=1}^n f(x_i)\nu V_i$ is large, to show that $S_{\boldsymbol{t}}(f,\nu)$ cannot be controlled by δ.)

>(d) Let $(X,\mathfrak{T},\Sigma,\mu)$ be an effectively locally finite τ-additive topological measure space in which μ is inner regular with respect to the closed sets and outer regular with respect to the open sets (see 412W). Let T be the straightforward set of tagged partitions generated by $X \times \{E : \mu E < \infty\}$, Δ the set of neighbourhood gauges on X, and $\Re = \{\mathcal{R}_{E\eta} : \mu E < \infty, \eta > 0\}$, where $\mathcal{R}_{E\eta} = \{F : \mu(F \cap E) \le \eta\}$, as in 481N. Show that if I_μ is the associated gauge integral, and $f : X \to \mathbb{R}$ is a function, then $I_\mu(f) = \int f d\mu$ if either is defined in $\mathbb{R}$.

(e) Let $\mathcal{C}$ be the set of non-empty subintervals of $X = [0,1]$, T the straightforward tagged-partition structure generated by $[0,1] \times \mathcal{C}$, and Δ the set of neighbourhood gauges on $[0,1]$, as in 481M. Let μ be any Radon measure on $[0,1]$, and I_μ the gauge integral defined from μ and the tagged-partition structure $([0,1],T,\Delta,\{\{\emptyset\}\})$. Show that, for any $f : [0,1] \to \mathbb{R}$, $I_\mu(f) = \int f d\mu$ if either is defined in $\mathbb{R}$.

(f) Let $\mathcal{C}$ be the set of non-empty subintervals of $[0,1]$, T the straightforward tagged-partition structure generated by $\{(x,C) : C \in \mathcal{C}, x \in \overline{C}\}$, and Δ the set of neighbourhood gauges on X, as in 481J. Let $\nu : \mathcal{C} \to \mathbb{R}$ be a bounded additive functional, and I_ν the gauge integral defined from ν and $(X,T,\Delta,\{\{\emptyset\}\})$. Show that $I_\nu(\chi[a,b[) = \lim_{x\uparrow a, y\uparrow b} \nu([x,y])$ whenever $0 < a < b \le 1$.

(g) Let $\mathcal{C}$ be the set of non-empty subintervals of $X = [0,1]$, T the straightforward tagged-partition structure generated by $\{(x,C) : C \in \mathcal{C},\ x \in \overline{C}\}$, and Δ the set of uniform metric gauges on $[0,1]$, as in 481I. Let μ be the Radon probability measure on $[0,1]$ such that $\mu\{\frac{1}{2}\} = 1$, and let $I_\mu = \lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\Re)} S_{\boldsymbol{t}}(\ ,\mu)$ be the corresponding gauge integral. Show that $I_\mu(\chi[0,1])$ is defined but that $I_\mu(\chi[0,\frac{1}{2}])$ is not.

>(h) (i) Show that the McShane integral on an interval $[a,b]$ as described in 481M coincides with the Lebesgue integral on $[a,b]$. (ii) Show that if $(X,\mathfrak{T},\Sigma,\mu)$ is a quasi-Radon measure space and μ is outer regular with respect to the open sets then the McShane integral as described in 481N coincides with the usual integral.

(i) Explain how the results in 481Xb-481Xc can be regarded as special cases of 482H.

(j) Let $(X,\mathfrak{T})$ be a topological space, $\mathcal{C}$ a ring of subsets of X, $T \subseteq [X \times \mathcal{C}]^{<\omega}$ a straightforward set of tagged partitions, $\nu : \mathcal{C} \to [0,\infty[$ an additive function, and Δ the family of neighbourhood gauges on X. Suppose that there is a sequence $\langle G_n\rangle_{n\in\mathbb{N}}$ of open sets, covering X, such that $\sup\{\nu C : C \in \mathcal{C},\ C \subseteq G_n\}$ is finite for every $n \in \mathbb{N}$. Show that ν is moderated with respect to T and Δ.

(k) Let $(X,\mathfrak{T},\Sigma,\mu)$ be a quasi-Radon measure space. Let T be the straightforward tagged-partition structure generated by $\{(x,E) : \mu E < \infty,\ x \in E\}$ and Δ the set of all neighbourhood gauges on X. Show that μ is moderated with respect to T and Δ iff there is a sequence of open sets of finite measure covering X.

482Y Further exercises (a) Set $X = \mathbb{R}$ and let $\mathcal{C}$ be the family of non-empty bounded intervals in X; set $Q = \{(x,C) : C \in \mathcal{C},\ x = \inf C\}$, and let T be the straightforward set of tagged partitions generated by Q. Let $\mathfrak{T}$ be the Sorgenfrey right-facing topology on X, and Δ the set of neighbourhood gauges for $\mathfrak{T}$. Set $\mathcal{R}_n = \{E : E \in \Sigma,\ \mu([-n,n] \cap E) \leq 2^{-n}\}$ for $n \in \mathbb{N}$, where μ is Lebesgue measure on $\mathbb{R}$ and Σ its domain, and write $\mathfrak{R} = \{\mathcal{R}_n : n \in \mathbb{N}\}$. Show that $(X,T,\Delta,\mathfrak{R})$ is a tagged-partition structure allowing subdivisions. Show that if $f : X \to \mathbb{R}$ is such that $I_\mu(f)$ is defined, then f is Lebesgue measurable.

(b) Give an example of X, $\mathfrak{T}$, Σ, μ, T, Δ, $\mathcal{C}$, f and C such that $(X,\mathfrak{T},\Sigma,\mu)$ is a compact metrizable Radon probability space, Δ is the set of all neighbourhood gauges on X, $(X,T,\Delta,\{\{\emptyset\}\})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$, $f : X \to \mathbb{R}$ is a function such that $I_\mu(f) = \lim_{\boldsymbol{t} \to \mathcal{F}(T,\Delta,\{\{\emptyset\}\})} S_{\boldsymbol{t}}(f,\mu)$ is defined, $C \in \mathcal{C}$ is a closed set with negligible boundary, and $I_\mu(f \times \chi C)$ is not defined.

(c) Suppose that, for $i = 1$ and $i = 2$, we have a tagged-partition structure $(X_i,T_i,\Delta_i,\mathfrak{R}_i)$ allowing subdivisions, witnessed by a ring $\mathcal{C}_i \subseteq \mathcal{P}X_i$, where X_i is a topological space, Δ_i is the set of all neighbourhood gauges on X_i, and $\mathfrak{R}_i$ is the simple residual structure complementary to $\mathcal{C}_i$, as in 481Yb. Set $X = X_1 \times X_2$ and let Δ be the set of neighbourhood gauges on X; set $\mathcal{C} = \{C \times D : C \in \mathcal{C}_1,\ D \in \mathcal{C}_2\}$; let $\mathfrak{R}$ be the simple residual structure on X complementary to $\mathcal{C}$; and let T be the straightforward tagged-partition structure generated by $\{((x,y),C \times D) : \{(x,C)\} \in T_1,\ \{(y,D)\} \in T_2\}$. For each i, let $\nu_i : \mathcal{C}_i \to [0,\infty[$ be a function moderated with respect to T_i and Δ_i, and define $\nu : \mathcal{C} \to [0,\infty[$ by setting $\nu(C \times D) = \nu_1 C \cdot \nu_2 D$ for $C \in \mathcal{C}_1$, $D \in \mathcal{C}_2$. Show that T is compatible with Δ and $\mathfrak{R}$. Let I_{ν_1}, I_{ν_2}, I_ν be the gauge integrals defined by these structures. Suppose that $f : X \to \mathbb{R}$ is such that $I_\nu(f)$ is defined. Set $f_x(y) = f(x,y)$ for $x \in X_1$, $y \in X_2$. Let $g : X_1 \to \mathbb{R}$ be any function such that $g(x) = I_{\nu_2}(f_x)$ whenever this is defined. Show that $I_{\nu_1}(g)$ is defined and equal to $I_\nu(f)$.

482 Notes and comments In 482E, 482F and 482G the long lists of conditions reflect the variety of possible applications of these arguments. The price to be paid for the versatility of the constructions here is a theory which is rather weak in the absence of special hypotheses. As everywhere in this book, I try to set ideas out in maximal convenient generality; you may feel that in this section the generality is becoming inconvenient; but the theory of gauge integrals has not, to my eye, matured to the point that we can classify the systems here even as provisionally as I set out to classify topological measure spaces in Chapters 41 and 43.

Enthusiasts for gauge integrals offer two substantial arguments for taking them seriously, apart from the universal argument in pure mathematics, that these structures offer new patterns for our delight and new challenges to our ingenuity. First, they say, gauge integrals integrate more functions than Lebesgue-type integrals, and it is the business of a theory of integration to integrate as many functions as possible; and secondly, gauge integrals offer an easier path to the principal theorems. I have to say that I think the first argument is sounder than the second. It is quite true that the Henstock integral on $\mathbb{R}$ (481K) can be rigorously defined in fewer words, and with fewer concepts, than the Lebesgue integral. The style of Chapters 11 and 12 is supposed to be better adapted to the novice than the style of this chapter, but you will have no difficulty in putting the ideas of 481A, 481C, 481J and 481K together into an elementary definition of an integral for real functions in which the only non-trivial argument is that establishing the existence of enough tagged partitions (481J), corresponding I suppose to Proposition 114D. But the path I took in defining the integral in §122, though arduous at that point, made (I hope) the convergence theorems of §123 reasonably natural; the proof of 482K, on the other hand, makes significant demands on our technique. Furthermore, the particular clarity of the one-dimensional Henstock integral is not repeated in higher dimensions. Fubini's theorem, with exact statement and full proof, even for products of Lebesgue measures on Euclidean spaces, is a lot to expect of an undergraduate; but Lebesgue measure on $\mathbb{R}^r$ makes sense in a way that it is quite hard to repeat with gauge integrals. (For instance, Lebesgue measure is invariant under isometries; this is not particularly easy to prove – see 263A – but at least it is true; if we want a gauge integral which is invariant under isometries, then we have to use a construction such as 481O, which does not directly match any natural general definition of 'product gauge integral' along the lines of 481P, 482M or 482Yc.)

In my view, a stronger argument for taking gauge integrals seriously is their 'power', that is, their ability to provide us with integrals of many functions in consistent ways. 482E, 482F and 482J give us an idea of what to expect. If we start from a measure space (X, Σ, μ) and build a gauge integral I_μ from a set $T \subseteq [X \times \Sigma]^{<\omega}$ of tagged partitions, then we can hope that integrable functions will be gauge-integrable, with the right integrals (482F); while gauge-integrable functions will be measurable (482E). What this means is that for *non-negative* functions, the integrals will coincide. Any 'new' gauge-integrable functions f will be such that $\int f^+ = \int f^- = \infty$; the gauge integral will offer a process for cancelling the divergent parts of these integrals. On the other hand, we can hope for a large class of gauge-integrable derivatives. In the next two sections, I will explain how this works in the Henstock and Pfeffer integrals. For simple examples calling for such procedures, see the formulae of §§282 and 283; for radical applications of the idea, see Muldowney 87.

Against this, gauge integrals are not effective in 'general' measure spaces, and cannot be, because there is no structure in an abstract measure space (X, Σ, μ) which allows us to cancel an infinite integral $\int f^+ = \int_F f$ against $\int f^- = \int_{X \setminus F} f$. Put another way, if a tagged-partition structure is invariant under all automorphisms of the structure (X, Σ, μ), as in 481Xf-481Xg, we cannot expect anything better than the standard integral. In order to get something new, the most important step seems to be the specification of a family $\mathcal{C}$ of 'regular' sets, preliminary to describing a set T of tagged partitions. To get a 'powerful' gauge integral, we want a fine filter on T, corresponding to a small set $\mathcal{C}$ and a large set of gauges. The residual families of 481F are generally introduced just to ensure 'compatibility' in the sense described there; as a rule, we try to keep them simple. But even if we take the set of all neighbourhood gauges, as in the Henstock integral, this is not enough unless we also sharply restrict both the family $\mathcal{C}$ and the permissible tags (482Xc-482Xe). The most successful restrictions, so far, have been 'geometric', as in 481J and 481O, and 484F below. Further limitations on admissible pairs (x, C), as in 481L and 481Q, in which $\mathcal{C}$ remains the set of intervals, but fewer tags are permitted, also lead to very interesting results.

Another limitation in the scope of gauge integrals is the difficulty they have in dealing with spaces of infinite measure. Of course we expect to have to specify a limiting procedure if we are to calculate $I_\mu(f)$ from sums $S_{\boldsymbol{t}}(f, \mu)$ which necessarily consider only sets of finite measure, and this is one of the functions of the collections $\mathfrak{R}$ of residual families. But this is not yet enough. In B.Levi's theorem (482K) we already need to suppose that our set-function ν is 'moderated' in order to determine how closely $f_n(x)$ needs to approximate each $f(x)$. The condition

$$S_{\boldsymbol{t}}(h, \nu) \leq 1 \text{ for every } \delta\text{-fine } \boldsymbol{t}$$

of 482Ib is very close to saying that $I_\mu(h) \leq 1$. But it is *not* the same as saying that μ is σ-finite; it suggests rather that X should be covered by a sequence of open sets of finite measure (482Xk).

Because gauge integrals are not absolute – that is, we can have $I_\nu(f)$ defined and finite while $I_\nu(|f|)$ is not – we are bound to have difficulties with integrals $\int_H f$, even if we interpret these in the simplest way, as $I_\nu(f \times \chi H)$, so that we do not need a theory of subspaces as developed in §214. 482G(iii)-(v) are an attempt to find a reasonably versatile sufficient set of conditions. The 'multiplier problem', for a given gauge integral I_ν, is the problem of characterizing the functions g such that $I_\nu(f \times g)$ is defined whenever $I_\nu(f)$ is defined, and even for some intensively studied integrals remains challenging. In 484L I will give an important case which is not covered by 482G.

One of the striking features of gauge integrals is that there is no need to assume that the set-function ν is countably additive. We can achieve countable additivity of the integral – in the form of B.Levi's theorem, for instance – by requiring only that the set of gauges should be 'countably full' (482K, 482L; contrast 482Xg). If we watch our definitions carefully, we can make this match the rules for Stieltjes integrals (114Xa, 482Xf). In 481Db I have already remarked on the potential use of gauge integrals in vector integration.

It is important to recognise that a value $F(E)$ of a Saks-Henstock indefinite integral (482B-482C) cannot be identified with either $I_\nu(f \times \chi E)$ or with $I_{\nu\restriction\mathcal{P}E}(f\restriction E)$, because in the formula $F(E) = \lim_{\boldsymbol{t}\to\mathcal{F}^*} S_{\boldsymbol{t}_E}(f,\nu)$ the tags of the partitions $\boldsymbol{t}_E$ need not lie in E. The idea of 482G is to impose sufficient conditions to ensure that the contributions of 'straddling' elements (x, C), where either $x \in H$ and $C \not\subseteq H$ or $x \notin H$ and $C \cap H \neq \emptyset$, are insignificant. To achieve this we seem to need both a regularity condition on the functional ν (condition (iii-β) of 482G) and a geometric condition on the set $\mathcal{C}$ underlying T (482G(iv)). As usual, the regularity condition required is closer to *outer* than to *inner* regularity, in contexts in which there is a distinction.

I am not sure that I have the 'right' version of Proposition 482E. The hypothesis there is that we have a metric space. But in the principal non-metrizable cases the result is still valid (482Xc-482Xe). Proposition 482H is a 'new' limit theorem; it has no counterpart in the ordinary theory of integration. The hypotheses seem, from where we are standing at the moment, to be exceedingly restrictive. In the leading examples in §483, however, the central requirement 482H(viii) is satisfied for straightforward reasons.

Gauge integrals insist on finite functions defined everywhere. But since we have an effective theory of negligible sets (482L), we can easily get a consistent theory of integration for functions which are defined and real-valued almost everywhere if we say that

$$I_\nu(f) = I_\nu(g) \text{ whenever } g : X \to \mathbb{R} \text{ extends } f\restriction f^{-1}[\mathbb{R}]$$

whenever $I_\nu(g) = I_\nu(g')$ for all such extensions.

483 The Henstock integral

I come now to the original gauge integral, the 'Henstock integral' for real functions. The first step is to check that the results of §482 can be applied to show that this is an extension of both the Lebesgue integral and the improper Riemann integral (483B), coinciding with the Lebesgue integral for non-negative functions (483C). It turns out that any Henstock integrable function can be approximated in a strong sense by a sequence of Lebesgue integrable functions (483G). The Henstock integral can be identified with the Perron and special Denjoy integrals (483J, 483N). Much of the rest of the section is concerned with indefinite Henstock integrals. Some of the results of §482 on tagged-partition structures allowing subdivisions condense into a particularly strong Saks-Henstock lemma (483F). If f is Henstock integrable, it is equal almost everywhere to the derivative of its Henstock integral (483I). Finally, indefinite Henstock integrals can be characterized as continuous ACG_* functions (483R).

483A Definition The following notation will apply throughout the section. Let $\mathcal{C}$ be the family of non-empty bounded intervals in $\mathbb{R}$, and let $T \subseteq [\mathbb{R}\times\mathcal{C}]^{<\omega}$ be the straightforward set of tagged partitions generated by $\{(x, C) : C \in \mathcal{C}, x \in \overline{C}\}$. Let Δ be the set of all neighbourhood gauges on $\mathbb{R}$. Set $\mathfrak{R} = \{\mathcal{R}_{ab} : a \leq b \in \mathbb{R}\}$, where $\mathcal{R}_{ab} = \{\mathbb{R} \setminus [c, d] : c \leq a,\ d \geq b\} \cup \{\emptyset\}$. Then $(\mathbb{R}, T, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions (481K), so T is compatible with Δ and $\mathfrak{R}$ (481Hf). The **Henstock integral** is the gauge integral defined by the process of 481E-481F from $(\mathbb{R}, T, \Delta, \mathfrak{R})$ and Lebesgue measure μ. For a function $f : \mathbb{R} \to \mathbb{R}$ I will say that f is **Henstock integrable**, and that $\int f = \gamma$, if $\lim_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\mathfrak{R})} S_{\boldsymbol{t}}(f,\mu)$ is defined and equal to $\gamma \in \mathbb{R}$. For α, $\beta \in [-\infty, \infty]$ I will write $\int_\alpha^\beta f$ for $\int f \times \chi\,]\alpha, \beta[$ if this is defined in $\mathbb{R}$. I will use the symbol $\int$ for the ordinary integral, so that $\int f d\mu$ is the Lebesgue integral of f.

483B Tracing through the theorems of §482, we have the following.

Theorem (a) Every Henstock integrable function on $\mathbb{R}$ is Lebesgue measurable.

(b) Every Lebesgue integrable function $f : \mathbb{R} \to \mathbb{R}$ is Henstock integrable, with the same integral.

(c) If f is Henstock integrable so is $f \times \chi C$ for every interval $C \subseteq \mathbb{R}$.

(d) Suppose that $f : \mathbb{R} \to \mathbb{R}$ is any function. Then

(α) if $\beta \in]-\infty, \infty]$, $\int_{-\infty}^{\beta} f = \lim_{b \uparrow \beta} \int_{-\infty}^{b} f$ if either is defined in $\mathbb{R}$,

(β) if $\alpha \in [-\infty, \infty[$, $\int_{\alpha}^{\infty} f = \lim_{a \downarrow \alpha} \int_{a}^{\infty} f$ if either is defined in $\mathbb{R}$.

proof (a) Apply 482E.

(b) Apply 482F, referring to 134F to confirm that condition 482F(ii) is satisfied.

(c)-(d)(i) The first thing to check is that the conditions of 482G are satisfied by $\mathbb{R}$, T, Δ, $\mathfrak{R}$, $\mathcal{C}$ and μ. **P** 482G(i) is just 481K, and 482G(ii) is trivial. 482G(iii-β) and 482G(v) are elementary, and so is 482G(iii-β); if you like, it is a special case of 412W(b-iii). As for 482G(iv), if $E \in \mathcal{C}$ is a singleton $\{x\}$, then whenever $(x, C) \in \mathcal{C}$ we can express C as a union of one or more of the sets $C \cap]-\infty, x[$, $C \cap \{x\}$ and $C \cap]x, \infty[$, and for any non-empty C' of these we have $\{(x, C')\} \in T$ and either $C' \subseteq E$ or $C' \cap E = \emptyset$. Otherwise, let $\eta > 0$ be half the length of E, and let δ be the uniform metric gauge $\{(x, A) : A \subseteq]x - \eta, x + \eta[\}$. Then if $x \in \partial E$ and $(x, C) \in T \cap \tilde{\delta}$, we can again express C as a union of one or more of the sets $C \cap]-\infty, x[$, $C \cap \{x\}$ and $C \cap]x, \infty[$, and these will witness that 482G(iv) is satisfied. **Q**

(ii) Now suppose that f is Henstock integrable. Then $\lim_{a \to -\infty, b \to \infty} \int_a^b f$ is defined and equal to $\int f$. **P** Let F be the Saks-Henstock indefinite integral of f (482B-482C). Then 482G tells us that $\int_a^b f$ is defined and equal to $F(]a, b[)$ whenever $a < b$ in $\mathbb{R}$. Now, given $\epsilon > 0$, there is an $\mathcal{R} \in \mathfrak{R}$ such that $|F(\mathbb{R} \setminus C)| \leq \epsilon$ whenever $C \in \mathcal{C}$ and $\mathbb{R} \setminus C \in \mathcal{R}$; that is, there are $a_0 \leq b_0$ such that $|\int f - \int_a^b f| \leq \epsilon$ whenever $a \leq a_0 \leq b_0 \leq b$. As ϵ is arbitrary, $\lim_{a \to -\infty, b \to \infty} \int_a^b f$ is defined and equal to $\int f$. **Q**

(iii) It follows that if f is Henstock integrable and $c \in \mathbb{R}$, $\lim_{b \to \infty} \int_c^b f$ is defined. **P** Let $\epsilon > 0$. Then there are $a_0 \leq c$, $b_0 \geq c$ such that $|\int_a^b f - \int f| \leq \epsilon$ whenever $a \leq a_0$ and $b \geq b_0$. But this means that if b, $b' \geq b_0$ then

$$|\int_c^b f - \int_c^{b'} f| = |\int_{a_0}^b f - \int_{a_0}^{b'} f| \leq 2\epsilon$$

whenever b, $b' \geq b_0$. As ϵ is arbitrary, $\lim_{b \to \infty} \int_c^b f$ is defined. **Q**

Similarly, $\lim_{a \to -\infty} \int_a^c f$ is defined.

(iv) Moreover, if f is Henstock integrable and $a < b$ in $\mathbb{R}$, then $\lim_{c \uparrow b} \int_a^c f$ is defined and equal to $\int_a^b f$. **P** Again let F be the Saks-Henstock indefinite integral of f. Let $\epsilon > 0$. Then there is a $\delta \in \Delta$ such that $\sum_{(x,C) \in \boldsymbol{t}} |F(C) - f(x)\mu C| \leq \epsilon$ whenever $\boldsymbol{t} \in T$ is δ-fine. Let $\eta > 0$ be such that $\eta |f(b)| \leq \epsilon$ and $(b, [c, b[) \in \delta$ whenever $b - \eta \leq c < b$. Then whenever $\max(a, b - \eta) \leq c < b$,

$$\int_a^b f - \int_a^c f = F([c, b[) \leq |F([c, b[) - f(b)\mu[c, b[| + |f(b)|\mu[c, b[\leq 2\epsilon.$$

As ϵ is arbitrary, $\lim_{c \uparrow b} \int_a^c f = \int_a^b f$. **Q**

Similarly, $\lim_{c \downarrow a} \int_c^b f$ is defined and equal to $\int_a^b f$.

(v) Next, if $f : \mathbb{R} \to \mathbb{R}$ and $c \in \mathbb{R}$ are such that $\gamma = \lim_{a \downarrow c, b \to \infty} \int_a^b f$ is defined in $\mathbb{R}$, then $\int_c^{\infty} f$ is defined and equal to γ. **P** I seek to apply 482H, with $H =]c, \infty[$. We have already seen that the conditions of 482G are satisfied, and 482H(vi)-(vii) are elementary, if we set $H_n =]c + 2^{-n}, c + 2^n[$. So we are left with 482H(viii). Given $\epsilon > 0$, let $\eta \in]0, 1]$, $b_0 \geq c + 1$ be such that $|\int_a^b f - \gamma| \leq \epsilon$ whenever $c < a \leq c + \eta$ and $b \geq b_0$. If we set

$$\begin{aligned}\delta_0 = &\{(x, A) : x < c,\ A \subseteq \left]-\infty, \tfrac{1}{2}(x + c)\right[\} \\ &\cup \{(c, A) : A \subseteq]c - \eta, c + \eta[\} \\ &\cup \{(x, A) : x > c,\ A \subseteq \left]\tfrac{1}{2}(x + c), \infty\right[\},\end{aligned}$$

$\delta_0 \in \Delta$. If $\boldsymbol{t} \in T$ is δ_0-fine and $\mathcal{R}_{c,b_0}$-filling, $W_{\boldsymbol{t}}$ is an interval including $[c, b_0]$ and $W_{\boldsymbol{t}\restriction H}$ must be an interval with infimum in $]c, c+\eta[$ and supremum at least b_0. So $|\gamma - \int f \times \chi W_{\boldsymbol{t}\restriction H}| \leq \epsilon$. As ϵ is arbitrary, condition 482H(viii) is satisfied, and $\int_c^\infty f$ is defined and equal to γ. **Q**

Similarly, $\int_\infty^c f = \lim_{a\to-\infty, b\uparrow c} \int_a^b f$ if the latter is defined.

(vi) We are now in a position to show that if f is Henstock integrable then $\int_c^\infty f = \lim_{b\to\infty} \int_c^b f$ is defined for every $c \in \mathbb{R}$. **P** By (iii) and (iv), $\lim_{a\downarrow c} \int_a^{c+1} f = \int_c^{c+1} f$ and $\lim_{b\to\infty} \int_{c+1}^b$ are both defined. Because $\int f \times \chi\{c\} = 0$, by (b),

$$\lim_{a\downarrow c, b\to\infty} \int_a^b = \int_c^{c+1} f + \lim_{b\to\infty} \int_{c+1}^b = \lim_{b\to\infty} \int_c^b f$$

is defined, and is equal to $\int_c^\infty f$, by (v). **Q**

Similarly, $\int_{-\infty}^c f = \lim_{a\to-\infty} \int_a^c f$ is defined. Putting these together, we see that if f is Henstock integrable and $a < b$ in $\mathbb{R}$,

$$\int_a^b f = \int (f \times \chi]a, \infty[) \times \chi]-\infty, b[$$

is defined. Once again, because $\int f \times \chi\{c\}$ is always defined, $\int f \times \chi C$ is defined for every interval C, and the proof of (c) is complete.

(vii) Now consider (d). If $\int_{-\infty}^\beta f$ is defined, then $g = f \times \chi]-\infty, \beta[$ is Henstock integrable. Taking any real $c < \beta$, we have

$$\lim_{b\uparrow\beta} \int_{-\infty}^b f = \lim_{b\uparrow\beta} \int_{-\infty}^b g = \int_{-\infty}^c g + \lim_{b\uparrow\beta} \int_c^b g = \int_{-\infty}^c g + \int_c^\beta g$$

(by (iii) or (iv))

$$= \int_\infty^\beta f.$$

In the other direction, suppose that $\gamma = \lim_{b\uparrow\beta} \int_{-\infty}^b f$ is defined, where $\beta \in \mathbb{R}$. Then

$$\lim_{b\uparrow\beta} \int_{\beta-1}^b f = \gamma - \int_{-\infty}^{\beta-1} f$$

is defined, and also $\lim_{a\to-\infty} \int_a^{\beta-1} f = \int_{-\infty}^{\beta-1} f$, by (iii). So $\lim_{a\to-\infty, b\uparrow b} \int_a^b f = \gamma$, and must be equal to $\int_\infty^\beta f$, by (v).

For the case $\beta = \infty$, suppose that $\gamma = \lim_{b\to\infty} \int_{-\infty}^b f$ is defined. Then

$$\lim_{a\downarrow 0, b\to\infty} \int_a^b f = \lim_{a\downarrow 0} \int_a^1 f + \lim_{b\to\infty} \int_1^b f$$
$$= \int_0^1 f + \gamma - \int_{-\infty}^1 f = \gamma - \int_{-\infty}^0 f$$

so, by (v), $\int_0^\infty f = \gamma - \int_{-\infty}^0 f$ and $\int f = \gamma$ are defined.

(viii) Similarly, if $\alpha \in [-\infty, \infty[$, $\int_\alpha^\infty f = \lim_{a\downarrow\alpha} \int_a^\infty f$ if either is defined in $\mathbb{R}$. This completes the proof.

483C Corollary The Henstock and Lebesgue integrals agree on non-negative functions, in the sense that if $f : \mathbb{R} \to [0, \infty[$ then $\int f = \int f d\mu$ if either is defined in $\mathbb{R}$.

proof If f is Lebesgue integrable, it is Henstock integrable, with the same integral, by 483Bb. If it is Henstock integrable, then it is measurable, by 483Ba, so that $\int f d\mu$ is defined in $[0, \infty]$; but

$$\int f d\mu = \sup\{\int g\, d\mu : g \leq f \text{ is a non-negative simple function}\}$$

(213B)

$$= \sup\{ \text{⨍} g : g \leq f \text{ is a non-negative simple function}\} \leq \text{⨍} f$$

(481Cb) is finite, so f is Lebesgue integrable.

483D Corollary If $f : \mathbb{R} \to \mathbb{R}$ is Henstock integrable, then $\alpha \mapsto \text{⨍}_{-\infty}^{\alpha} f : [\infty, \infty] \to \mathbb{R}$ and $(\alpha, \beta) \mapsto \text{⨍}_{\alpha}^{\beta} f : [-\infty, \infty]^2 \to \mathbb{R}$ are continuous and bounded.

proof Set $F(x) = \text{⨍}_{-\infty}^{x} f$ for $x \in \mathbb{R}$. Take any $x_0 \in \mathbb{R}$ and $\epsilon > 0$. By 483B(d-i), there is an $\eta_1 > 0$ such that $|\text{⨍}_{-\infty}^{x} f - \text{⨍}_{-\infty}^{x_0} f| \leq \epsilon$ whenever $x_0 - \eta_1 \leq x \leq x_0$. By 483B(d-ii), there is an $\eta_2 > 0$ such that $|\text{⨍}_{x}^{\infty} f - \text{⨍}_{x_0}^{\infty} f| \leq \epsilon$ whenever $x_0 \leq x \leq x_0 + \eta_2$. But this means that $|F(x) - F(x_0)| \leq \epsilon$ whenever $x_0 - \eta_1 \leq x \leq x_0 + \eta_2$. As ϵ is arbitrary, F is continuous at x_0.

We know also that $\lim_{x\to\infty} F(x) = \text{⨍} f$ is defined in $\mathbb{R}$; while

$$\lim_{x\to-\infty} F(x) = \text{⨍} f - \lim_{x\to-\infty} \text{⨍}_{x}^{\infty} f = 0$$

is also defined, by 483B(d-ii), as usual. So F is continuous at $\pm\infty$.

Now writing $G(\alpha, \beta) = \text{⨍}_{\alpha}^{\beta} f$, we have $G(\alpha, \beta) = F(\beta) - F(\alpha)$ if $\alpha \leq \beta$ and zero if $\beta \leq \alpha$. So G also is continuous. F and G are bounded because $[-\infty, \infty]$ is compact.

483E Definition If $f : \mathbb{R} \to \mathbb{R}$ is Henstock integrable, then its **indefinite Henstock integral** is the function $F : \mathbb{R} \to \mathbb{R}$ defined by saying that $F(x) = \text{⨍}_{-\infty}^{x} f$ for every $x \in \mathbb{R}$.

483F In the present context, the Saks-Henstock lemma can be sharpened, as follows.

Theorem Let $f : \mathbb{R} \to \mathbb{R}$ and $F : \mathbb{R} \to \mathbb{R}$ be functions. Then the following are equiveridical:

(i) f is Henstock integrable and F is its indefinite Henstock integral;

(ii)(α) F is continuous,

(β) $\lim_{x\to-\infty} F(x) = 0$ and $\lim_{x\to\infty} F(x)$ is defined in $\mathbb{R}$,

(γ) for every $\epsilon > 0$ there are a gauge $\delta \in \Delta$ and a non-decreasing function $\phi : \mathbb{R} \to [0, \epsilon]$ such that $|f(x)(b-a) - F(b) + F(a)| \leq \phi(b) - \phi(a)$ whenever $a \leq x \leq b$ in $\mathbb{R}$ and $(x, [a, b]) \in \delta$.

proof (i)⇒(ii) (α)-(β) are covered by 483D. As for (γ), 482G tells us that we can identify the Saks-Henstock indefinite integral of f with $E \mapsto \text{⨍} f \times \chi E : \mathcal{E} \to \mathbb{R}$, where $\mathcal{E}$ is the algebra generated by $\mathcal{C}$. Let $\epsilon > 0$. Then there is a $\delta \in \Delta$ such that $\sum_{(x,C)\in\boldsymbol{t}} |f(x)\mu C - \text{⨍} f \times \chi C| \leq \epsilon$ for every δ-fine $\boldsymbol{t} \in T$. Set

$$\phi(a) = \sup_{\boldsymbol{t}\in T\cap\delta} \textstyle\sum_{(x,C)\in\boldsymbol{t}, C\subseteq]-\infty,a]} |f(x)\mu C - \text{⨍} f \times \chi C|,$$

so that $\phi : \mathbb{R} \to [0, \epsilon]$ is a non-decreasing function. Now suppose that $a \leq y \leq b$ and that $(y, [a, b]) \in \delta$. In this case, whenever $\boldsymbol{t} \in T \cap \delta$, $\boldsymbol{s} = \{(x, C) : (x, C) \in \boldsymbol{t},\ C \subseteq]-\infty, a]\} \cup \{(y,]a, b[)\}$ also belongs to $T \cap \delta$. Now $F(b) - F(a) = \text{⨍}_{a}^{b} f$, so

$$\begin{aligned}\phi(b) &\geq \sum_{(x,C)\in\boldsymbol{s}} |f(x)\mu C - \text{⨍} f \times \chi C| \\ &= \sum_{(x,C)\in\boldsymbol{t}, C\subseteq]-\infty,a]} |f(x)\mu C - \text{⨍} f \times \chi C| + |f(y)(b-a) - F(b) + F(a)|.\end{aligned}$$

As $\boldsymbol{t}$ is arbitrary,

$$\phi(b) \geq \phi(a) + |f(y)(b-a) - F(b) + F(a)|,$$

that is, $|f(y)(b-a) - F(b) + F(a)| \leq \phi(b) - \phi(a)$, as called for by ($\gamma$).

(ii)⇒(i) Assume (ii). Set $\gamma = \lim_{x\to\infty} F(x)$. Let $\epsilon > 0$. Let $a \le b$ be such that $|F(x)| \le \epsilon$ for every $x \le a$ and $|F(x) - \gamma| \le \epsilon$ for every $x \ge b$. Let $\delta \in \Delta$, $\phi : \mathbb{R} \to [0, \epsilon]$ be such that ϕ is non-decreasing and $|f(x)(\beta - \alpha) - F(\beta) + F(\alpha)| \le \phi(\beta) - \phi(\alpha)$ whenever $\alpha \le x \le \beta$ and $(x, [\alpha, \beta]) \in \delta$. Let $\delta' \in \Delta$ be such that $(x, \overline{A}) \in \delta$ whenever $(x, A) \in \delta'$. For $C \in \mathcal{C}$ set $\lambda C = F(\sup C) - F(\inf C)$, $\nu C = \phi(\sup C) - \phi(\inf C)$; then if $(x, C) \in \delta'$, $(x, [\inf C, \sup C]) \in \delta$, so $|f(x)\mu C - \lambda C| \le \nu C$. Note that λ and ν are both additive in the sense that $\lambda(C \cup C') = \lambda C + \lambda C'$, $\nu(C \cup C') = \nu C + \nu C'$ whenever C, C' are disjoint members of $\mathcal{C}$ such that $C \cup C' \in \mathcal{C}$ (cf. 482G(iii-α)).

Let $\boldsymbol{t} \in T$ be δ'-fine and $\mathcal{R}_{ab}$-filling. Then $W_{\boldsymbol{t}}$ is of the form $[c, d]$ where $c \le a$ and $b \le d$. So

$$\begin{aligned}|S_{\boldsymbol{t}}(f,\mu) - \gamma| &\le 2\epsilon + |S_{\boldsymbol{t}}(f,\mu) - F(d) + F(c)| = 2\epsilon + |S_{\boldsymbol{t}}(f,\mu) - \lambda[c,d]| \\ &= 2\epsilon + |\sum_{(x,C)\in\boldsymbol{t}} f(x)\mu C - \lambda C| \le 2\epsilon + \sum_{(x,C)\in\boldsymbol{t}} \nu C \\ &= 2\epsilon + \nu[c,d] \le 3\epsilon.\end{aligned}$$

As ϵ is arbitrary, f is Henstock integrable, with integral γ.

I still have to check that F is the indefinite integral of f. Set $F_1(x) = \int_{-\infty}^{x} f$ for $x \in \mathbb{R}$, and $G = F - F_1$. Then (ii) applies equally to the pair (f, F_1), because (i)⇒(ii). So, given $\epsilon > 0$, we have δ, $\delta_1 \in \Delta$ and non-decreasing functions ϕ, $\phi_1 : \mathbb{R} \to [0, \epsilon]$ such that

$|f(x)(b-a) - F(b) + F(a)| \le \phi(b) - \phi(a)$ whenever $a \le x \le b$ in $\mathbb{R}$ and $(x, [a, b]) \in \delta$,

$|f(x)(b-a) - F_1(b) + F_1(a)| \le \phi_1(b) - \phi_1(a)$ whenever $a \le x \le b$ in $\mathbb{R}$ and $(x, [a, b]) \in \delta_1$.

Putting these together,

$|G(b) - G(a)| \le \psi(b) - \psi(a)$ whenever $a \le x \le b$ in $\mathbb{R}$ and $(x, [a, b]) \in \delta \cap \delta_1$,

where $\psi = \phi + \phi_1$. But if $a \le b$ in $\mathbb{R}$, there are $a_0 \le x_0 \le a_1 \le x_1 \le \ldots \le x_{n-1} \le a_n$ such that $a = a_0$, $a_n = b$ and $(x_i, [a_i, a_{i+1}]) \in \delta$ for $i < n$ (481J), so that

$$\begin{aligned}|G(b) - G(a)| &\le \sum_{i=0}^{n-1} |G(a_{i+1}) - G(a_i)| \\ &\le \sum_{i=0}^{n-1} \psi(a_{i+1}) - \psi(a_i) = \psi(b) - \psi(a) \le 2\epsilon.\end{aligned}$$

As ϵ is arbitrary, G is constant. As $\lim_{x\to-\infty} F(x) = \lim_{x\to-\infty} F_1(x) = 0$, $F = F_1$, as required.

483G Theorem (see Gordon 94, 9.18) Let $f : \mathbb{R} \to \mathbb{R}$ be a Henstock integrable function. Then there is a countable cover $\mathcal{K}$ of $\mathbb{R}$ by compact sets such that $f \times \chi K$ is Lebesgue integrable for every $K \in \mathcal{K}$.

proof (a) For $n \in \mathbb{N}$ set $E_n = \{x : |x| \le n, |f(x)| \le n\}$. By 483Ba, f is Lebesgue measurable, so for each $n \in \mathbb{N}$ we can find a compact set $K_n \subseteq E_n$ such that $\mu(E_n \setminus K_n) \le 2^{-n}$; f is Lebesgue integrable over K_n, and $Y = \mathbb{R} \setminus \bigcup_{n\in\mathbb{N}} K_n$ is Lebesgue negligible.

Let F be the indefinite Henstock integral of f, and take a gauge $\delta_0 \in \Delta$ and a non-decreasing function $\phi : \mathbb{R} \to [0, 1]$ such that $|f(x)(b-a) - F(b) + F(a)| \le \phi(b) - \phi(a)$ whenever $a \le x \le b$ and $(x, [a, b]) \in \delta_0$ (483F). Because $\int |f| \times \chi Y = \int_Y |f| d\mu = 0$ (483Bb), there is a $\delta_1 \in \Delta$ such that $S_{\boldsymbol{t}}(|f| \times \chi Y, \mu) \le 1$ whenever $\boldsymbol{t} \in T$ is δ_1-fine (482Ad). For $C \in \mathcal{C}$, set $\lambda C = F(\sup C) - F(\inf C)$, $\nu C = \phi(\sup C) - \phi(\inf C)$. Set

$$D_n = \{x : x \in E_n \cap Y, (x, [a, b]) \in \delta_0 \cap \delta_1 \text{ whenever } x - 2^{-n} \le a \le x \le b \le x + 2^{-n}\},$$

so that $\bigcup_{n\in\mathbb{N}} D_n = Y$; set $K_n' = \overline{D}_n$, so that K_n' is compact and $\bigcup_{n\in\mathbb{N}} K_n' \supseteq Y$.

(b) The point is that $f \times \chi K_n'$ is Lebesgue integrable for each n. **P** For $k \in \mathbb{N}$, let A_k be the set of points $x \in K_n'$ such that $\left]x, x + 2^{-k}\right] \cap K_n' = \emptyset$; then A_k is finite, because $K_n' \subseteq [-n, n]$ is bounded. Similarly, if $A_k' = \{x : x \in K_n', \left[x - 2^{-k}, x\right[\cap K_n' = \emptyset\}$, A_k' is finite. Set $B = K_n' \setminus \bigcup_{k\in\mathbb{N}}(A_k \cup A_k')$, so that $K_n' \setminus B$ is countable.

Set

$$\delta = \delta_0 \cap \delta_1 \cap \{(x, A) : x \in \mathbb{R}, A \subseteq \left]x - 2^{-n-1}, x + 2^{-n-1}\right[\},$$

so that $\delta \in \Delta$. Note that if $C \in \mathcal{C}$, $x \in B \cap \overline{C}$ and $(x, C) \in \delta$ and $\mu C > 0$, then $\operatorname{int} C$ meets K'_n (because there are points of K'_n arbitrarily close to x on both sides) so $\operatorname{int} C$ meets D_n; and if $y \in D_n \cap \operatorname{int} C$ then $(y, C) \in \delta_0 \cap \delta_1$, because $\operatorname{diam} C \leq 2^{-n}$. This means that if $\boldsymbol{t} \in T$ is δ-fine and $\boldsymbol{t} \subseteq B \times \mathcal{C}$, then there is a $\delta_0 \cap \delta_1$-fine $\boldsymbol{s} \in T$ such that $\boldsymbol{s} \subseteq D_n \times \mathcal{C}$, $W_{\boldsymbol{s}} \subseteq W_{\boldsymbol{t}}$ and whenever $(x, C) \in \boldsymbol{t}$ and C is not a singleton, there is a y such that $(y, C) \in \boldsymbol{s}$. Accordingly

$$\begin{aligned}\sum_{(x,C)\in\boldsymbol{t}} |\lambda C| &\leq \sum_{(y,C)\in\boldsymbol{s}} |\lambda C| \leq \sum_{(y,C)\in\boldsymbol{s}} |f(y)\mu C - \lambda C| + \sum_{(y,C)\in\boldsymbol{s}} |f(y)|\mu C \\ &\leq \sum_{(y,C)\in\boldsymbol{s}} \nu C + S_{\boldsymbol{s}}(|f| \times \chi Y, \mu) \leq 2.\end{aligned}$$

But this means that if $\boldsymbol{t} \in T$ is δ-fine,

$$S_{\boldsymbol{t}}(|f \times \chi B|, \mu) = \sum_{(x,C)\in\boldsymbol{t}\restriction B} |f(x)\mu C|$$

(where $\boldsymbol{t}\restriction B = \boldsymbol{t} \cap (B \times \mathcal{C})$)

$$\begin{aligned}&\leq \sum_{(x,C)\in\boldsymbol{t}\restriction B} |f(x)\mu C - \lambda C| + \sum_{(x,C)\in\boldsymbol{t}\restriction B} |\lambda C| \\ &\leq \sum_{(x,C)\in\boldsymbol{t}\restriction B} \nu C + 2 \leq 3.\end{aligned}$$

It follows that if g is a μ-simple function and $0 \leq g \leq |f \times \chi B|$,

$$\begin{aligned}\int g\,d\mu = \fint g &\leq \sup_{\boldsymbol{t}\in T \text{ is } \delta\text{-fine}} S_{\boldsymbol{t}}(g, \mu) \\ &\leq \sup_{\boldsymbol{t}\in T \text{ is } \delta\text{-fine}} S_{\boldsymbol{t}}(|f \times \chi B|, \mu) \leq 3,\end{aligned}$$

and $|f \times \chi B|$ is μ-integrable, by 213B, so $f \times \chi B$ is μ-integrable, by 122P. As $K'_n \setminus B$ is countable, therefore negligible, $f \times \chi K'_n$ is μ-integrable. **Q**

(c) So if we set $\mathcal{K} = \{K_n : n \in \mathbb{N}\} \cup \{K'_n : n \in \mathbb{N}\}$, we have a suitable family.

483H Upper and lower derivates: Definition Let $F : \mathbb{R} \to \mathbb{R}$ be any function. For $x \in \mathbb{R}$, set

$$D^*F(x) = \limsup_{y\to x} \frac{F(y)-F(x)}{y-x}, \quad D_*F(x) = \liminf_{y\to x} \frac{F(y)-F(x)}{y-x}$$

in $[-\infty, \infty]$.

483I Theorem Suppose that $f : \mathbb{R} \to \mathbb{R}$ is Henstock integrable, and F is its indefinite Henstock integral. Then $F'(x)$ is defined and equal to $f(x)$ for almost every $x \in \mathbb{R}$.

proof For $n \in \mathbb{N}$, set $A_n = \{x : |x| \leq n, D^*F(x) > f(x) + 2^{-n}\}$. Then $\mu^* A_n \leq 2^{-n+1}$. **P** Let $\delta \in \Delta$ and $\phi : \mathbb{R} \to [0, 4^{-n}]$ be such that ϕ is non-decreasing and $|f(x)(b-a) - F(b) + F(a)| \leq \phi(b) - \phi(a)$ whenever $a \leq x \leq b$ and $(x, [a, b]) \in \delta$ (483F). Let $\mathcal{I}$ be the set of non-trivial closed intervals $[a, b] \subseteq \mathbb{R}$ such that, for some $x \in [a, b] \cap A_n$, $(x, [a, b]) \in \delta$ and $\frac{F(b)-F(a)}{b-a} \geq f(x) + 2^{-n}$. By Vitali's theorem (221A) we can find a countable disjoint family $\mathcal{I}_0 \subseteq \mathcal{I}$ such that $A_n \setminus \bigcup \mathcal{I}_0$ is negligible; so we have a finite family $\mathcal{I}_1 \subseteq \mathcal{I}_0$ such that $\mu^*(A_n \setminus \bigcup \mathcal{I}_1) \leq 2^{-n}$. Enumerate $\mathcal{I}_1$ as $\langle [a_i, b_i] \rangle_{i<m}$, and for each $i < m$ take $x_i \in [a_i, b_i] \cap A_n$ such that $(x_i, [a_i, b_i]) \in \delta$ and $F(b_i) - F(a_i) \geq (b_i - a_i)(f(x_i) + 2^{-n})$. Then

$$\phi(b_i) - \phi(a_i) \geq |f(x_i)(b_i - a_i) - F(b_i) + F(a_i)| \geq 2^{-n}(b_i - a_i)$$

for each $i < m$, so

$$\mu(\bigcup \mathcal{I}_1) = \sum_{i<m} b_i - a_i \leq 2^n \sum_{i<m} \phi(b_i) - \phi(a_i) \leq 2^{-n},$$

and $\mu^* A_n \leq 2^{-n+1}$. **Q**

Accordingly $\{x : D^*F(x) > f(x)\} = \bigcup_{m\in\mathbb{N}} \bigcap_{n\geq m} A_n$ is negligible. Similarly, or applying the argument to $-f$, $\{x : D_*F(x) < f(x)\}$ is negligible. So $D^*F \leq_{\text{a.e.}} f \leq_{\text{a.e.}} D_*F$. Since $D_*F \leq D^*F$ everywhere, $D^*F =_{\text{a.e.}} D_*F =_{\text{a.e.}} f$. But $F'(x) = f(x)$ whenever $D^*F(x) = D_*F(x) = f(x)$, so we have the result.

483J Theorem Let $f : \mathbb{R} \to \mathbb{R}$ be a function. Then the following are equiveridical:

(i) f is Henstock integrable;

(ii) for every $\epsilon > 0$ there are functions F_1, $F_2 : \mathbb{R} \to \mathbb{R}$, with finite limits at both $-\infty$ and ∞, such that $D^*F_1(x) \leq f(x) \leq D_*F_2(x)$ and $0 \leq F_2(x) - F_1(x) \leq \epsilon$ for every $x \in \mathbb{R}$.

proof (i)⇒(ii) Suppose that f is Henstock integrable and that $\epsilon > 0$. Set $F(x) = \int_{-\infty}^{x} f$ for $x \in \mathbb{R}$. Let $\delta \in \Delta$, $\phi : \mathbb{R} \to [0, \frac{1}{2}\epsilon]$ be such that ϕ is non-decreasing and $|f(x)(b-a) - F(b) + F(a)| \leq \phi(b) - \phi(a)$ whenever $a \leq x \leq b$ and $(x, [a, b]) \in \delta$ (483F). Set $F_1 = F - \phi$, $F_2 = F + \phi$; then $F_1(x) \leq F_2(x) \leq F_1(x) + \epsilon$ for every $x \in \mathbb{R}$, and the limits at $\pm\infty$ are defined because F and ϕ both have limits at both ends. If $x \in \mathbb{R}$, there is an $\eta > 0$ such that $(x, A) \in \delta$ whenever $A \subseteq [x - \eta, x + \eta]$. So if $x - \eta \leq a \leq x \leq b \leq x + \eta$ and $a < b$,

$$|\tfrac{F(b)-F(a)}{b-a} - f(x)| \leq \tfrac{\phi(b)-\phi(a)}{b-a},$$

and

$$\tfrac{F_1(b)-F_1(a)}{b-a} \leq f(x) \leq \tfrac{F_2(b)-F_2(a)}{b-a}.$$

In particular, this is true whenever $x - \eta \leq a < x = b$ or $x = a < b \leq x + \eta$. So $D^*F_1(x) \leq f(x) \leq D_*F_2(x)$. As x is arbitrary, we have a suitable pair F_1, F_2.

(ii)⇒(i) Suppose that (ii) is true. Take any $\epsilon > 0$. Let F_1, $F_2 : \mathbb{R} \to \mathbb{R}$ be as in the statement of (ii).

(α) We need to know that $F_2 - F_1$ is non-decreasing. **P** Set $G = F_2 - F_1$. Then

$$\begin{aligned}\liminf_{y\to x} \tfrac{G(y)-G(x)}{y-x} &= \liminf_{y\to x} \tfrac{F_2(y)-F_2(x)}{y-x} - \tfrac{F_1(y)-F_1(x)}{y-x} \\ &\geq \liminf_{y\to x} \tfrac{F_2(y)-F_2(x)}{y-x} - \limsup_{y\to x} \tfrac{F_1(y)-F_1(x)}{y-x} \\ &\text{(2A3Sf)} \\ &= D_*F_2(x) - D^*F_1(x) \geq 0.\end{aligned}$$

? If $a < b$ and $G(a) > G(b)$, set $\gamma = \frac{G(a)-G(b)}{2(b-a)}$, and choose $\langle a_n\rangle_{n\in\mathbb{N}}$, $\langle b_n\rangle_{n\in\mathbb{N}}$ inductively as follows. $a_0 = a$ and $b_0 = b$. Given that $a_n < b_n$ and $G(a_n) - G(b_n) > \gamma(b_n - a_n)$, set $c = \frac{1}{2}(a_n + b_n)$; then either $G(a_n) - G(c) > \gamma(c - a_n)$ or $G(c) - G(b_n) \geq \gamma(b_n - c)$; in the former case, take $a_{n+1} = a_n$ and $b_{n+1} = c$; in the latter, take $a_{n+1} = c$ and $b_{n+1} = b_n$. Set $x = \lim_{n\to\infty} a_n = \lim_{n\to\infty} b_n$. Then for each n, either $G(a_n) - G(x) > \gamma(x - a_n)$ or $G(x) - G(b_n) > \gamma(b_n - x)$. In either case, we have a y such that $0 < |y - x| \leq 2^{-n}(b - a)$ and $\frac{G(y)-G(x)}{y-x} < -\gamma$. So $D_*G(x) \leq -\gamma < 0$, which is impossible. **X**

Thus G is non-decreasing, as required. **Q**

(β) Let $a \leq b$ be such that $|F_1(x) - F_1(a)| \leq \epsilon$ whenever $x \leq a$ and $|F_1(x) - F_1(b)| \leq \epsilon$ whenever $x \geq b$. Let $h : \mathbb{R} \to]0, \infty[$ be a strictly positive integrable function such that $\int h\, d\mu \leq \epsilon$. Then $\int h \leq \epsilon$, by 483Bb, so there is a $\delta_0 \in \Delta$ such that $S_{\boldsymbol{t}}(h, \mu) \leq 2\epsilon$ for every δ_0-fine $\boldsymbol{t} \in T$ (482Ad). For $x \in \mathbb{R}$ let $\eta_x > 0$ be such that

$$\tfrac{F_1(y)-F_1(x)}{y-x} \leq f(x) + h(x), \quad \tfrac{F_2(y)-F_2(x)}{y-x} \geq f(x) - h(x)$$

whenever $0 < |y - x| \leq 2\eta_x$; set $\delta = \{(x, A) : (x, A) \in \delta_0, A \subseteq]x - \eta_x, x + \eta_x[\}$, so that $\delta \in \Delta$. Note that if $x \in \mathbb{R}$ and $x - \eta_x \leq \alpha \leq x \leq \beta \leq x + \eta_x$, then

$$F_1(\beta)-F_1(x)\le(\beta-x)(f(x)+h(x)),\quad F_1(x)-F_1(\alpha)\le(x-\alpha)(f(x)+h(x)),$$

so that $F_1(\beta)-F_1(\alpha)\le(\beta-\alpha)(f(x)+h(x))$; and similarly $F_2(\beta)-F_2(\alpha)\ge(\beta-\alpha)(f(x)-h(x))$.

For $C\in\mathcal{C}$, set

$$\lambda_1C=F_1(\sup C)-F_2(\sup C),\quad \lambda_2C=F_2(\sup C)-F_2(\sup C).$$

Then if $C\in\mathcal{C}$, $x\in\overline{C}$ and $(x,C)\in\delta$,

$$\lambda_1C\le(f(x)+h(x))\mu C,\quad \lambda_2C\ge(f(x)-h(x))\mu C.$$

Suppose that $\boldsymbol{t}\in T$ is δ-fine and $\mathcal{R}_{ab}$-filling. Then $W_{\boldsymbol{t}}=[\alpha,\beta]$ for some $\alpha\le a$, $\beta\ge b$, so that

$$\begin{aligned}S_{\boldsymbol{t}}(f,\mu)&=\sum_{(x,C)\in\boldsymbol{t}}f(x)\mu C\le\sum_{(x,C)\in\boldsymbol{t}}\lambda_2C+h(x)\mu C=\lambda_2[\alpha,\beta]+S_{\boldsymbol{t}}(h,\mu)\\&\le F_2(\beta)-F_2(\alpha)+2\epsilon\le F_1(\beta)-F_1(\alpha)+3\epsilon\le F_1(b)-F_1(a)+5\epsilon.\end{aligned}$$

Similarly,

$$\begin{aligned}S_{\boldsymbol{t}}(f,\mu)&=\sum_{(x,C)\in\boldsymbol{t}}f(x)\mu C\ge\sum_{(x,C)\in\boldsymbol{t}}\lambda_1C-h(x)\mu C\\&=\lambda_1[\alpha,\beta]-S_{\boldsymbol{t}}(h,\mu)\ge F_1(\beta)-F_1(\alpha)-2\epsilon\ge F_1(b)-F_1(a)-4\epsilon.\end{aligned}$$

But this means that if $\boldsymbol{t}$, $\boldsymbol{t}'$ are two δ-fine $\mathcal{R}_{ab}$-filling members of T, $|S_{\boldsymbol{t}}(f,\mu)-S_{\boldsymbol{t}'}(f,\mu)|\le9\epsilon$. As ϵ is arbitrary,

$$\lim_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\Re)}S_{\boldsymbol{t}}(f,\mu)=\text{⨍}f$$

is defined.

Remark The formulation (ii) above is a version of the method of integration described by Perron 14.

483K Proposition Let $f:\mathbb{R}\to\mathbb{R}$ be a Henstock integrable function, and F its indefinite Henstock integral. Then $F[E]$ is Lebesgue negligible for every Lebesgue negligible set $E\subseteq\mathbb{R}$.

proof Let $\epsilon>0$. By 483C and 482Ad, as usual, together with 483F, there are a $\delta\in\Delta$ and a non-decreasing $\phi:\mathbb{R}\to[0,\epsilon]$ such that

$$S_{\boldsymbol{t}}(|f|\times\chi E,\mu)\le\epsilon,\quad |f(x)(b-a)-F(b)+F(a)|\le\phi(b)-\phi(a)$$

whenever $\boldsymbol{t}\in T$ is δ-fine, $a\le x\le b$ and $(x,[a,b])\in\delta$. For $n\in\mathbb{N}$ and $i\in\mathbb{Z}$, set

$$E_{ni}=\{x:x\in E\cap[2^{-n}i,2^{-n}(i+1)[\,,\,(x,A)\in\delta\text{ whenever }A\subseteq[x-2^{-n},x+2^{-n}]\}.$$

Set $J_n=\{i:i\in\mathbb{Z},\,-4^n<i\le4^n,\,E_{ni}\ne\emptyset\}$. Observe that

$$E=\textstyle\bigcup_{n\in\mathbb{N}}\bigcap_{m\ge n}\bigcup_{i\in J_m}E_{mi}.$$

For $i\in J_n$, take x_{ni}, $y_{ni}\in E_{ni}$ such that $x_{ni}\le y_{ni}$ and

$$\min(F(x_{ni}),F(y_{ni}))\le\inf F[E_{ni}]+4^{-n}\epsilon,$$

$$\max(F(x_{ni}),F(y_{ni}))\ge\sup F[E_{ni}]-4^{-n}\epsilon,$$

so that $\mu^*F[E_{ni}]\le|F(y_{ni})-F(x_{ni})|+2^{-2n+1}\epsilon$. Now, for each $i\in J_n$, $(x_{ni},[x_{ni},y_{ni}])\in\mathcal{C}\cap\delta$, while $[x_{ni},y_{ni}]\subseteq[2^{-n}i,2^{-n}(i+1)[$, so $\boldsymbol{t}=\{(x_{ni},[x_{ni},y_{ni}]):i\in J_n\}$ is a δ-fine member of T, and

$$\begin{aligned}\mu^*F[\bigcup_{i\in J_n}E_{ni}]&\le\sum_{i\in J_n}\mu^*F[E_{ni}]\le\sum_{i\in J_n}2^{-2n+1}\epsilon+|F(y_{ni})-F(x_{ni})|\\&\le4\epsilon+\sum_{i\in J_n}|f(x_{ni})(y_{ni}-x_{ni})|+\sum_{i\in J_n}\phi(y_{ni})-\phi(x_{ni})\\&\le4\epsilon+S_{\boldsymbol{t}}(|f|\times\chi E,\mu)+\epsilon\le6\epsilon.\end{aligned}$$

Since this is true for every $n\in\mathbb{N}$,

$$\begin{aligned}\mu^*F[E] &= \mu^*F[\bigcup_{n\in\mathbb{N}}\bigcap_{m\geq n}\bigcup_{i\in J_m}E_i]\\ &= \mu^*(\bigcup_{n\in\mathbb{N}}F[\bigcap_{m\geq n}\bigcup_{i\in J_m}E_i]) = \sup_{n\in\mathbb{N}}\mu^*F[\bigcap_{m\geq n}\bigcup_{i\in J_m}E_i]\\ &\leq 6\epsilon.\end{aligned} \tag{132Ae}$$

As ϵ is arbitrary, $F[E]$ is negligible, as claimed.

483L Definition If $f : \mathbb{R} \to \mathbb{R}$ is Henstock integrable, I write $\|f\|_H$ for $\sup_{a\leq b} |\int_a^b f|$. It is elementary to check that this is a seminorm on the linear space of all Henstock integrable functions. (It is finite-valued by 483D.)

483M Proposition (a) If $f : \mathbb{R} \to \mathbb{R}$ is Henstock integrable, then $|\int f| \leq \|f\|_H$, and $\|f\|_H = 0$ iff $f = 0$ a.e.

(b) Write $\mathcal{HL}^1$ for the linear space of all Henstock integrable real-valued functions on $\mathbb{R}$, and HL^1 for $\{f^\bullet : f \in \mathcal{HL}^1\} \subseteq L^0(\mu)$ (§241). If we write $\|f^\bullet\|_H = \|f\|_H$ for every $f \in \mathcal{HL}^1$, then HL^1 is a normed space. The ordinary space $L^1(\mu)$ of equivalence classes of Lebesgue integrable functions is a linear subspace of HL^1, and $\|u\|_H \leq \|u\|_1$ for every $u \in L^1(\mu)$.

(c) We have a linear operator $T : HL^1 \to C_b(\mathbb{R})$ defined by saying that $T(f^\bullet)$ is the indefinite Henstock integral of f for every $f \in \mathcal{HL}^1$, and $\|T\| = 1$.

proof (a) Of course

$$|\int f| = \lim_{a\to-\infty,b\to\infty} |\int_a^b f| \leq \|f\|_H$$

(using 438Bd). Set $F(x) = \int_{-\infty}^x f$, so that $F(b) - F(a) = \int_a^b f$ whenever $a \leq b$. If $f = 0$ a.e., then $F(x) = \int_{-\infty}^x f d\mu = 0$ for every x, by 483B, so $\|f\|_H = 0$. If $\|f\|_H = 0$, then F is constant, so $f = F' = 0$ a.e., by 483I.

(b) This follows immediately from (a). (Compare the definitions of the norms $\|\ \|_p$ on L^p, for $1 \leq p \leq \infty$, in §§242-244.) By 483Bb, $L^1(\mu) \subseteq HL^1$, and

$$\|u\|_H \leq \|u^+\|_H + \|u^-\|_H = \|u^+\|_1 + \|u^-\|_1 = \|u\|_1$$

for every $u \in L^1(\mu)$, writing u^+ and u^- for the positive and negative parts of u, as in Chapter 24.

(c) If $f, g \in \mathcal{HL}^1$ and $f^\bullet = g^\bullet$, then f and g have the same indefinite integral, by 483Bb or otherwise; so T is defined as a function from HL^1 to $\mathbb{R}^{\mathbb{R}}$. By 483F, Tu is continuous and bounded for every $u \in HL^1$, and by 481C T is linear. If $f \in \mathcal{HL}^1$ and $Tf^\bullet = F$, then $\|f\|_H = \sup_{x,y\in\mathbb{R}} |F(y) - F(x)|$; since $\lim_{x\to-\infty} F(x) = 0$, $\|f\|_H \geq \|F\|_\infty$; as f is arbitrary, $\|T\| \leq 1$. On the other hand, for any non-negative Lebesgue integrable function f, $\|Tf^\bullet\|_\infty = \|f\|_1 = \|f\|_H$, so $\|T\| = 1$.

483N Proposition Suppose that $\langle I_k\rangle_{k\in K}$ is a disjoint family of open intervals in $\mathbb{R}$ with union G, and that $f : \mathbb{R} \to \mathbb{R}$ is a function such that $f_k = f \times \chi I_k$ is Henstock integrable for every $k \in K$. If $\sum_{k\in K} \|f_k\|_H < \infty$, then $f \times \chi G$ is Henstock integrable, and $\int f \times \chi G = \sum_{k\in K} \int f_k$.

proof I seek to apply 482H. We have already seen, in the proof of 483B, that the conditions of 482G are satisfied by $\mathbb{R}$, T, Δ, $\mathfrak{R}$, $\mathcal{C}$, $\mathfrak{T}$ and μ. Of course $G = \bigcup_{k\in K} I_k$ is the union of a sequence of open sets over which f is Henstock integrable. So we have only to check 482H(viii).

Set

$$\delta_0 = \bigcup_{k\in K}\{(x, A) : x \in I_k,\ A \subseteq I_k\} \cup \{(x, A) : x \in \mathbb{R} \setminus G,\ A \subseteq \mathbb{R}\},$$

so that $\delta_0 \in \Delta$. For each $k \in K$ let F_k be the Saks-Henstock indefinite integral of f_k. Let $\epsilon > 0$. Then there is a finite set $K_0 \subseteq K$ such that $\sum_{k\in K\setminus K_0} \|f_k\|_H \leq \epsilon$. Next, there must be $\delta_1 \in \Delta$ and $\mathcal{R} \in \mathfrak{R}$ such that

$$\sum_{k\in K_0} |\fint f_k - S_{\boldsymbol{t}}(f_k,\mu)| \le \epsilon$$

for every δ-fine $\mathcal{R}$-filling $\boldsymbol{t}\in T$, and $\delta_2\in\Delta$ such that $\sum_{k\in K_0}|S_{\boldsymbol{t}}(f_k,\mu)-F_k(W_{\boldsymbol{t}})|\le\epsilon$ for every δ_2-fine $\boldsymbol{t}\in T$.

Now let $\boldsymbol{t}\in T$ be $(\delta_0\cap\delta_1\cap\delta_2)$-fine and $\mathcal{R}$-filling. For each $k\in K$ set $\boldsymbol{t}_k=\boldsymbol{t}\restriction I_k$, so that $\boldsymbol{t}\restriction G=\bigcup_{k\in K}\boldsymbol{t}_k$. Because $W_{\boldsymbol{t}}$ is an interval, each $W_{\boldsymbol{t}_k}$ must be an interval, and it is a subinterval of I_k because $\boldsymbol{t}$ is δ_0-fine. So (using 482G)

$$|F_k(W_{\boldsymbol{t}_k})| = |\fint f_k\times\chi W_{\boldsymbol{t}_k}| \le \|f_k\|_H.$$

Also

$$\begin{aligned}\sum_{k\in K_0}|\fint f_k - \fint f\times\chi W_{\boldsymbol{t}_k}| &\le \sum_{k\in K_0}|\fint f_k - S_{\boldsymbol{t}}(f_k,\mu)| + \sum_{k\in K_0}|S_{\boldsymbol{t}}(f_k,\mu)-F_k(W_{\boldsymbol{t}_k}|\\ &\le 2\epsilon.\end{aligned}$$

On the other hand,

$$\sum_{k\in K\setminus K_0}|\fint f_k - \fint f\times\chi W_{\boldsymbol{t}_k}| \le 2\sum_{k\in K\setminus K_0}\|f_k\|_H \le 2\epsilon.$$

Putting these together,

$$|\fint f\times\chi W_{\boldsymbol{t}\restriction G} - \sum_{k\in K}\fint f_k| = |\sum_{k\in K}\fint f\times\chi W_{\boldsymbol{t}_k} - \sum_{k\in K}\fint f_k|$$

(because $\boldsymbol{t}$ is finite, so all but finitely many terms in the sum $\sum_{k\in K} f\times\chi W_{\boldsymbol{t}_k}$ are zero)

$$\le \sum_{k\in K}|\fint f\times\chi W_{\boldsymbol{t}_k} - \fint f_k| \le 4\epsilon.$$

As ϵ is arbitrary, condition 482H(viii) is satisfied, with

$$\lim_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\Re)}\fint f\times\chi W_{\boldsymbol{t}\restriction G} = \sum_{k\in K}\fint f_k,$$

and 482H gives the result we seek.

483O Definitions (a) For any real-valued function F, write $\omega(F)$ for $\sup_{x,y\in\operatorname{dom}F}|F(x)-F(y)|$, the **oscillation** of F. (Interpret $\sup\emptyset$ as 0, so that $\omega(\emptyset)=0$.)

(b) Let $F:\mathbb{R}\to\mathbb{R}$ be a function. For $A\subseteq\mathbb{R}$, we say that F is $\mathbf{AC}_*$ **on** A if for every $\epsilon>0$ there is an $\eta>0$ such that $\sum_{I\in\mathcal{I}}\omega(F\restriction\overline{I})\le\epsilon$ whenever $\mathcal{I}$ is a disjoint family of open intervals with endpoints in A and $\sum_{I\in\mathcal{I}}\mu I\le\eta$. Note that whether F is AC_* on A is *not* determined by $F\restriction A$, since it depends on the behaviour of F on intervals with endpoints in A.

(c) Finally, F is $\mathbf{ACG}_*$ if it is continuous and there is a countable family $\mathcal{A}$ of sets, covering $\mathbb{R}$, such that F is AC_* on every member of $\mathcal{A}$.

483P Elementary results (a)(i) If $F,G:\mathbb{R}\to\mathbb{R}$ are functions and $A\subseteq B\subseteq\mathbb{R}$, then $\omega(F+G\restriction A)\le\omega(F\restriction A)+\omega(G\restriction A)$ and $\omega(F\restriction A)\le\omega(F\restriction B)$.

(ii) If F is the indefinite Henstock integral of $f:\mathbb{R}\to\mathbb{R}$ and $C\subseteq\mathbb{R}$ is an interval, then $\|f\times\chi C\|_H=\omega(F\restriction C)$.

(iii) If $F:\mathbb{R}\to\mathbb{R}$ is continuous, then $(a,b)\mapsto\omega(F\restriction[a,b]):\mathbb{R}^2\to\mathbb{R}$ is continuous, and $\omega(F\restriction\overline{A})=\omega(F\restriction A)$ for every set $A\subseteq\mathbb{R}$.

(b)(i) If $F:\mathbb{R}\to\mathbb{R}$ is AC_* on $A\subseteq\mathbb{R}$, it is AC_* on every subset of A.

(ii) If $F:\mathbb{R}\to\mathbb{R}$ is continuous and is AC_* on $A\subseteq\mathbb{R}$, it is AC_* on $\overline{A}$. **P** Let $\epsilon>0$. Let $\eta>0$ be such that $\sum_{I\in\mathcal{I}}\omega(F\restriction\overline{I})\le\epsilon$ whenever $\mathcal{I}$ is a disjoint family of open intervals with endpoints in A and $\sum_{I\in\mathcal{I}}\mu I\le\eta$. Let $\mathcal{I}$ be a disjoint family of open intervals with endpoints in $\overline{A}$ and $\sum_{I\in\mathcal{I}}\mu I\le\frac12\eta$. Let

$\mathcal{I}_0 \subseteq \mathcal{I}$ be a non-empty finite set; then we can enumerate $\mathcal{I}_0$ as $\langle]a_i, b_i[\rangle_{i \le n}$ where $a_0, b_0, \ldots, a_n, b_n \in \overline{A}$ and $a_0 \le b_0 \le a_1 \le b_1 \le \ldots \le a_n \le b_n$. Because $(a,b) \mapsto \omega(F\restriction[a,b])$ is continuous, as noted in (a-ii) above, we can find $a_0', \ldots, b_n' \in A$ such that $a_0' \le b_0' \le a_1' \le \ldots \le a_n' \le b_n'$, $\sum_{i=0}^n b_i' - a_i' \le \eta$, and $\sum_{i=0}^n |\omega(F\restriction[a_i', b_i']) - \omega(F\restriction[a_i, b_i])| \le \epsilon$; so that

$$\sum_{I \in \mathcal{I}_0} \omega(F\restriction\overline{I}) \le \sum_{i=0}^n \omega(F\restriction[a_i', b_i']) \le 2\epsilon.$$

As $\mathcal{I}_0$ is arbitrary, $\sum_{I \in \mathcal{I}} \omega(F\restriction\overline{I}) \le 2\epsilon$; as ϵ is arbitrary, F is AC_* on $\overline{A}$. **Q**

483Q Lemma Let $F : \mathbb{R} \to \mathbb{R}$ be a continuous function, and $K \subseteq \mathbb{R}$ a non-empty compact set such that F is AC_* on K. Write $\mathcal{I}$ for the family of non-empty bounded open intervals, disjoint from K, with endpoints in K.

(a) $\sum_{I \in \mathcal{I}} \omega(F\restriction I)$ is finite.

(b) Write a^* for $\inf K = \min K$. Then there is a Lebesgue integrable function $g : \mathbb{R} \to \mathbb{R}$ such that

$$F(x) - F(a^*) = \int_{a^*}^x g + \sum_{J \in \mathcal{I}, J \subseteq [a^*, x]} F(\sup J) - F(\inf J)$$

for every $x \in K$.

proof (a) Let $\eta > 0$ be such that $\sum_{I \in \mathcal{J}} \omega(F\restriction\overline{I}) \le 1$ whenever $\mathcal{J}$ is a disjoint family of open intervals with endpoints in K and $\sum_{I \in \mathcal{J}} \mu I \le \eta$. Let m_0, $m_1 \in \mathbb{Z}$ be such that $K \subseteq [m_0\eta, m_1\eta]$. For integers m between m_0 and m_1, let $\mathcal{I}_m$ be the set of intervals in $\mathcal{I}$ included in $]j\eta, (j+1)\eta[$. Then $\sum_{I \in \mathcal{I}_m} \mu I \le \eta$, so $\sum_{I \in \mathcal{I}_m} \omega(F\restriction I) \le 1$ for each j. Also every member of $\mathcal{J} = \mathcal{I} \setminus \bigcup_{m_0 \le m < m_1} \mathcal{I}_m$ contains $m\eta$ for some m between m_0 and m_1, so $\#(\mathcal{J}) \le m_1 - m_0$. Accordingly

$$\begin{aligned}\sum_{I \in \mathcal{I}} \omega(F\restriction\overline{I}) &\le \sum_{I \in \mathcal{J}} \omega(F\restriction\overline{I}) + \sum_{m=m_0}^{m_1-1} \sum_{I \in \mathcal{I}_m} \omega(F\restriction\overline{I}) \\ &\le \sum_{I \in \mathcal{J}} \omega(F\restriction\overline{I}) + m_1 - m_0 < \infty\end{aligned}$$

because F is continuous, therefore bounded on every bounded interval.

(b)(i) Set $b^* = \sup K = \max K$. Define $G : [a^*, b^*] \to \mathbb{R}$ by setting

$$\begin{aligned}G(x) &= F(x) \text{ if } x \in K, \\ &= \tfrac{F(b)(x-a)+F(a)(b-x)}{b-a} \text{ if } x \in]a,b[\in \mathcal{I}.\end{aligned}$$

Then G is absolutely continuous. **P** G is continuous because F is. Let $\epsilon > 0$. Let $\eta_1 > 0$ be such that $\sum_{I \in \mathcal{J}} \omega(F\restriction\overline{I}) \le \epsilon$ whenever $\mathcal{J}$ is a disjoint family of open intervals with endpoints in K and $\sum_{I \in \mathcal{J}} \mu I \le \eta_1$. Let $\mathcal{I}_0 \subseteq \mathcal{I}$ be a finite set such that $\sum_{I \in \mathcal{I} \setminus \mathcal{I}_0} \omega(F\restriction\overline{I}) \le \epsilon$, and take $M > 0$ such that $|F(b) - F(a)| \le M(b-a)$ whenever $]a,b[\in \mathcal{I}_0$; set $\eta = \min(\eta_1, \frac{\epsilon}{M}) > 0$.

Let $\mathcal{J}^*$ be the set of non-empty open subintervals J of $[a^*, b^*]$ such that either $J \cap K = \emptyset$ or both endpoints of J belong to K. Let $\mathcal{J} \subseteq \mathcal{J}^*$ be a disjoint family such that $\sum_{I \in \mathcal{J}} \mu I \le \eta$. Set $\mathcal{J}' = \{J : J \in \mathcal{J},\ J \cap K = \emptyset\}$. Then

$$\begin{aligned}\sum_{J \in \mathcal{J} \setminus \mathcal{J}'} |G(\sup J) - G(\inf J)| &= \sum_{J \in \mathcal{J} \setminus \mathcal{J}'} |F(\sup J) - F(\inf J)| \\ &\le \sum_{J \in \mathcal{J} \setminus \mathcal{J}'} \omega(F\restriction\overline{J}) \le \epsilon.\end{aligned}$$

On the other hand,

$$\sum_{J\in\mathcal{J}'} |G(\sup J) - G(\inf J)| = \sum_{I\in\mathcal{I}_0} \sum_{J\in\mathcal{J},J\subseteq I} |G(\sup J) - G(\inf J)| + \sum_{I\in\mathcal{I}\setminus\mathcal{I}_0} \sum_{J\in\mathcal{J},J\subseteq I} |G(\sup J) - G(\inf J)|$$
$$\leq M \sum_{I\in\mathcal{I}_0} \sum_{J\in\mathcal{J},J\subseteq I} \mu J + \sum_{I\in\mathcal{I}\setminus\mathcal{I}_0} |F(\sup I) - F(\inf I)|$$

(because G is monotonic on $\overline{I}$ for each $I \in \mathcal{I}$)

$$\leq M\eta + \epsilon \leq 2\epsilon,$$

so $\sum_{J\in\mathcal{J}} |G(\sup J) - G(\inf J)| \leq 3\epsilon$.

Generally, if J is any non-empty open subinterval of $[a^*, b^*]$, we can split it into at most three intervals belonging to $\mathcal{J}^*$. So if $\mathcal{J}$ is any disjoint family of non-empty open subintervals of $[a^*, b^*]$ with $\sum_{J\in\mathcal{J}} \mu J \leq \eta$, we can find a family $\tilde{\mathcal{J}} \subseteq \mathcal{J}^*$ with $\sum_{J\in\tilde{\mathcal{J}}} \mu J = \sum_{J\in\mathcal{J}} \mu J$ and $\sum_{J\in\tilde{\mathcal{J}}} |G(\sup J) - G(\inf J)| \geq \sum_{J\in\mathcal{J}} |G(\sup J) - G(\inf J)|$. But this means that $\sum_{J\in\mathcal{J}} |G(\sup J) - G(\inf J)| \leq 3\epsilon$. As ϵ is arbitrary, G is absolutely continuous. **Q**

(ii) By 225E, G' is Lebesgue integrable and $G(x) = G(a^*) + \int_{a^*}^x G'$ for every $x \in [a^*, b^*]$. Set $g(x) = G'(x)$ when $x \in K$ and $G'(x)$ is defined, 0 for other $x \in \mathbb{R}$, so that $g : \mathbb{R} \to \mathbb{R}$ is Lebesgue integrable. Now take any $x \in K$. Then

$$F(x) = G(x) = G(a^*) + \int_{a^*}^x G'$$
$$= F(a^*) + \int_{a^*}^x g + \int_{[a^*,x]\setminus K} G'$$
$$= F(a^*) + \int_{a^*}^x g + \sum_{I\in\mathcal{I},I\subseteq[a^*,x]} \int_I G'$$

(because $\mathcal{I}$ is a disjoint countable family of measurable sets, and $\bigcup_{I\in\mathcal{I},I\subseteq[a^*,x]} I = [a^*, x] \setminus K$)

$$= F(a^*) + \int_{a^*}^x g + \sum_{I\in\mathcal{I},I\subseteq[a^*,x]} G(\sup I) - G(\inf I)$$

(note that this sum is absolutely summable)

$$= F(a^*) + \int_{a^*}^x g + \sum_{I\in\mathcal{I},I\subseteq[a^*,x]} F(\sup I) - F(\inf I)$$

as required.

483R Theorem (see GORDON 94, 11.14) Let $F : \mathbb{R} \to \mathbb{R}$ be a function. Then F is an indefinite Henstock integral iff it is ACG_*, $\lim_{x\to-\infty} F(x) = 0$ and $\lim_{x\to\infty} F(x)$ is defined in $\mathbb{R}$.

proof (a) Suppose that F is the indefinite Henstock integral of $f : \mathbb{R} \to \mathbb{R}$.

(i) By 483F, F is continuous, with limit zero at $-\infty$ and finite at ∞. So I have just to show that there is a sequence of sets, covering $\mathbb{R}$, on each of which F is AC_*. Recall that there is a sequence $\langle K_m\rangle_{m\in\mathbb{N}}$ of compact sets, covering $\mathbb{R}$, such that $f \times K_m$ is Lebesgue integrable for every $m \in \mathbb{N}$ (483G). By the arguments of (i)⇒(ii) in the proof of 483J, there is a function $F_2 \geq F$ such that $D_*F_2 \geq f$ and $F_2 - F$ is non-decreasing and takes values between 0 and 1. For $n \in \mathbb{N}$, $j \in \mathbb{Z}$ set

$$I_{nj} = [2^{-n}j, 2^{-n}(j+1)],$$

$$B_{nj} = \{x : x \in I_{nj}, \tfrac{F_2(y)-F_2(x)}{y-x} \geq -n \text{ whenever } y \in I_{nj} \setminus \{x\}\}.$$

Observe that $\bigcup_{n\in\mathbb{N},j\in\mathbb{Z}} B_{nj} = \mathbb{R}$, so that $\{B_{nj}\cap K_m : m, n\in\mathbb{N}, j\in\mathbb{Z}\}$ is a countable cover of $\mathbb{R}$. It will therefore be enough to show that F is AC_* on every $B_{nj}\cap K_m$.

(ii) Fix $m, n\in\mathbb{N}$ and $j\in\mathbb{Z}$, and set $A = B_{nj}\cap K_m$. If $A=\emptyset$, then of course F is AC_* on A; suppose that A is not empty. Set $G(x) = F_2(x) + nx$ for $x\in I_{nj}$, so that $F = G - (F_2 - F) - H$ on I_{nj}, where $H(x) = nx$. Whenever a, $b\in B_{nj}$ and $a\le x\le b$, then $G(a)\le G(x)\le G(b)$, because $x\in I_{nj}$. So if $a_0, b_0, a_1, b_1, \dots, a_k, b_k\in A$ and $a_0\le b_0\le a_1\le b_1\le\ldots\le a_k\le b_k$,

$$\textstyle\sum_{i=0}^k \omega(G\restriction[a_i,b_i]) \le \sum_{i=0}^k G(b_i) - G(a_i) = G(b_k) - G(a_0) \le \omega(G\restriction I_{nj}),$$

and

$$\begin{aligned}\sum_{i=0}^k \omega(F\restriction[a_i,b_i]) &\le \sum_{i=0}^k \omega(G\restriction[a_i,b_i]) + \sum_{i=0}^k \omega(F-F_2\restriction[a_i,b_i]) + \sum_{i=0}^k \omega(H\restriction[a_i,b_i])\\ &\le \omega(G\restriction I_{nj}) + \omega(F-F_2\restriction I_{nj}) + \omega(H\restriction I_{nj})\end{aligned}$$

(because $F-F_2$ and H are monotonic)

$$\begin{aligned}&\le \omega(F\restriction I_{nj}) + 2\omega(F-F_2\restriction I_{nj}) + 2\omega(H\restriction I_{nj})\\ &\le \omega(F\restriction I_{nj}) + 2(1+n\mu I_{nj}) = M\end{aligned}$$

say, which is finite, because F is bounded.

(iii) By 2A2I (or 4A2Rj), the open set $\mathbb{R}\setminus\overline{A}$ is expressible as a countable union of disjoint non-empty open intervals. Two of these are unbounded; let $\mathcal{I}$ be the set consisting of the rest, so that $\overline{A}\cup\bigcup\mathcal{I} = [a^*, b^*]$ is a closed interval included in I_{nj}. If I, I' are distinct members of $\mathcal{I}$ and $\inf I\le\inf I'$, then $\sup I\le\inf I'$, because $I\cap I' = \emptyset$, and there must be a point of $\overline{A}$ in the interval $[\sup I, \inf I']$; so in fact there must be a point of A in this interval. It follows that $\sum_{I\in\mathcal{I}}\omega(F\restriction I)\le M$. **P** If $\mathcal{I}_0\subseteq\mathcal{I}$ is finite and non-empty, we can enumerate it as $\langle I_i\rangle_{i\le k}$ where $\sup I_i\le\inf I_{i'}$ whenever $i<i'\le k$. We can find $a_0,\dots,a_{k+1}\in A$ such that $a_0\le\inf I_0$, $\sup I_i\le a_{i+1}\le\inf I_{i+1}$ for every $i<k$, and $\sup I_k\le a_{k+1}$; so that

$$\textstyle\sum_{I\in\mathcal{I}_0}\omega(F\restriction I) = \sum_{i=0}^k \omega(F\restriction I_i) \le \sum_{i=0}^k \omega(F\restriction[a_i,a_{i+1}]) \le M.$$

As $\mathcal{I}_0$ is arbitrary, this gives the result. **Q**

(iv) Whenever $a^*\le x\le y\le b^*$,

$$|F(y)-F(x)| \le \textstyle\int_{\overline{A}\cap[x,y]} |f|d\mu + \sum_{I\in\mathcal{I}}\omega(F\restriction I\cap\,]x,y[).$$

P For each $I\in\mathcal{I}$,

$$\|f\times\chi(I\cap\,]x,y[)\|_H = \omega(F\restriction I\cap\,]x,y[) \le \omega(F\restriction I)$$

(483P(a-i)). So

$$\textstyle\sum_{I\in\mathcal{I}}\|f\times\chi(I\cap\,]x,y[)\|_H \le \sum_{I\in\mathcal{I}}\omega(F\restriction I)$$

is finite. Writing $H = \,]x,y[\,\cap\bigcup\mathcal{I}$, $\int f\times\chi H$ is defined and equal to $\sum_{I\in\mathcal{I}}\int f\times\chi(I\cap\,]x,y[)$, by 483N. On the other hand,

$$]x,y[\setminus H\subseteq\overline{A}\subseteq K_m,$$

so $f\times\chi(]x,y[\setminus H)$ is Lebesgue integrable. Accordingly

$$\begin{aligned}|F(y)-F(x)| &= |\textstyle\int f\times\chi\,]x,y[\,|\\ &\le |\textstyle\int f\times\chi H| + |\int f\times\chi(]x,y[\setminus H)d\mu|\\ &\le \sum_{I\in\mathcal{I}} |\textstyle\int f\times\chi(I\cap\,]x,y[)| + \int_{\overline{A}\cap[x,y]}|f|d\mu\\ &\le \sum_{I\in\mathcal{I}}\omega(F\restriction I\cap\,]x,y[) + \int_{\overline{A}\cap[x,y]}|f|d\mu,\end{aligned}$$

as claimed. **Q**

(v) So if $a^* \le a \le b \le b^*$,

$$\omega(F\restriction[a,b]) \le \sum_{I\in\mathcal{I}} \omega(F\restriction I\cap[a,b]) + \int_{\overline{A}\cap[a,b]} |f|d\mu.$$

P We have only to observe that if $a \le x \le y \le b$, then $\omega(F\restriction I\cap]x,y[) \le \omega(F\restriction I\cap[a,b])$ for every $I\in\mathcal{I}$, and $\int_{\overline{A}\cap]x,y[}|f|d\mu \le \int_{\overline{A}\cap[a,b]}|f|d\mu$. **Q**

(vi) Now let $\epsilon>0$. Setting $\tilde{F}(x) = \int_{a^*}^x f\times\chi\overline{A}d\mu$ for $x\in[a^*,b^*]$, $\tilde{F}$ is absolutely continuous (225E), and there is an $\eta_0>0$ such that $\sum_{i=0}^k |\tilde{F}(b_i)-\tilde{F}(a_i)|\le\epsilon$ whenever $a^*\le a_0\le b_0\le a_1\le b_1\le\ldots\le a_k\le b_k\le b^*$ and $\sum_{i=0}^k b_i-a_i\le\eta_0$. Take $\mathcal{I}_0\subseteq\mathcal{I}$ to be a finite set such that $\sum_{I\in\mathcal{I}\setminus\mathcal{I}_0}\omega(F\restriction I)\le\epsilon$, and let $\eta>0$ be such that $\eta\le\eta_0$ and $\eta<\operatorname{diam} I$ for every $I\in\mathcal{I}_0$.

Suppose that $a_0,b_0,\ldots,a_k,b_k\in A$ are such that $a_0\le b_0\le\ldots\le a_k\le b_k$ and $\sum_{i=0}^k b_i-a_i\le\eta$. Then no member of $\mathcal{I}_0$ can be included in any interval $[a_i,b_i]$, and therefore, because no a_i or b_i can belong to $\bigcup\mathcal{I}$, no member of $\mathcal{I}_0$ meets any $[a_i,b_i]$. Also, of course, $a^*\le a_0$ and $b_k\le b^*$. We therefore have

$$\begin{aligned}\sum_{i=0}^k \omega(F\restriction[a_i,b_i]) &\le \sum_{i=0}^k\sum_{I\in\mathcal{I}}\omega(F\restriction I\cap[a_i,b_i]) + \int_{\overline{A}\cap[a_i,b_i]}|f|d\mu\\ &= \sum_{i=0}^k\sum_{I\in\mathcal{I}\setminus\mathcal{I}_0}\omega(F\restriction I\cap[a_i,b_i]) + \sum_{i=0}^k \tilde{F}(b_i)-\tilde{F}(a_i)\\ &\le \sum_{i=0}^k \sum_{I\in\mathcal{I}\setminus\mathcal{I}_0, I\subseteq[a_i,b_i]}\omega(F\restriction I)+\epsilon\end{aligned}$$

(because if $I\in\mathcal{I}$ meets $[a_i,b_i]$, it is included in it)

$$\le \sum_{I\in\mathcal{I}\setminus\mathcal{I}_0}\omega(F\restriction I)+\epsilon\le 2\epsilon.$$

As ϵ is arbitrary, F is AC_* on A. This completes the proof that F is ACG_* and therefore satisfies the conditions (α) and (β).

(b) Now suppose that F satisfies the conditions. Set $F(-\infty)=0$ and $F(\infty)=\lim_{x\to\infty}F(x)$, so that $F:[-\infty,\infty]\to\mathbb{R}$ is continuous. For $x\in\mathbb{R}$, set $f(x)=F'(x)$ if this is defined, 0 otherwise. Let $\mathcal{J}$ be the family of all non-empty intervals $C\subseteq\mathbb{R}$ such that $\int f\times\chi C$ is defined and equal to $F(\sup C)-F(\inf C)$, and let $\mathcal{I}$ be the set of non-empty open intervals I such that every non-empty subinterval of I belongs to $\mathcal{J}$. I seek to show that $\mathbb{R}$ belongs to $\mathcal{I}$.

(i) Of course singleton intervals belong to $\mathcal{J}$. If $C_1,C_2\in\mathcal{J}$ are disjoint and $C=C_1\cup C_2$ is an interval, then

$$\begin{aligned}\int f\times\chi C &= \int f\times\chi C_1 + \int f\times\chi C_2\\ &= F(\sup C_1)-F(\inf C_1)+F(\sup C_2)-F(\inf C_2)\\ &= F(\sup C)-F(\inf C)\end{aligned}$$

and $C\in\mathcal{J}$. If $I_1,I_2\in\mathcal{I}$ and $I_1\cap I_2$ is non-empty, then $I_1\cup I_2$ is an interval; also any subinterval C of $I_1\cup I_2$ is either included in one of the I_j or is expressible as a disjoint union $C_1\cup C_2$ where C_j is a subinterval of I_j for each j; so $C\in\mathcal{J}$ and $I\in\mathcal{I}$. If $I_1,I_2\in\mathcal{I}$ and $\sup I_1=\inf I_2$, then $I=I_1\cup I_2\cup\{\sup I_1\}\in\mathcal{I}$, because any subinterval of I is expressible as the disjoint union of at most three intervals in $\mathcal{J}$.

(ii) If $\mathcal{I}_0\subseteq\mathcal{I}$ is non-empty and upwards-directed, then $\bigcup\mathcal{I}_0\in\mathcal{I}$. **P** This is a consequence of 483Bd. If we take a non-empty open subinterval J of $\bigcup\mathcal{I}_0$ and express it as $]\alpha,\beta[$, where $-\infty\le\alpha<\beta\le\infty$, and take any $x\in J$, then for any $b\in[x,\beta[$ there is some member I of $\mathcal{I}$ including $[x,b]$, so $\int f\times\chi\,]x,b[= F(b)-F(x)$; now $\lim_{b\uparrow\beta}F(b)=F(\beta)$, so 483Bd tells us that $\int f\times\chi\,]x,b[$ is defined and equal to $F(b)-F(x)$. Similarly,

using 483B(d-β), $\int f\times\chi\,]a,x[= F(x)-F(a)$, so $\int f\times\chi\,]a,b[= F(b)-F(a)$. Thus $J\in\mathcal{J}$. I wrote this out for open intervals, for convenience; but any non-empty subinterval of $\bigcup\mathcal{I}_0$ is either a singleton or expressible as an open interval with at most two points added, so belongs to $\mathcal{J}$. Accordingly $\bigcup\mathcal{I}_0\in\mathcal{I}$. **Q**

(iii) It follows that every member of $\mathcal{I}$ is included in a maximal member of $\mathcal{I}$. Let $\mathcal{I}^*$ be the set of maximal members of $\mathcal{I}$. By (i), these are all disjoint, so no endpoint of any member of $\mathcal{I}^*$ can belong to $\bigcup\mathcal{I}^*$.

? Suppose, if possible, that $\mathbb{R}\notin\mathcal{I}$. Then $\bigcup\mathcal{I}=\bigcup\mathcal{I}^*$ cannot be $\mathbb{R}$, and $V=\mathbb{R}\setminus\bigcup\mathcal{I}$ is a non-empty closed set. By (i), no two distinct members of $\mathcal{I}^*$ can share a boundary point, so V has no isolated points.

We are supposing that F is ACG_*, so there is a countable family $\mathcal{A}$ of sets, covering $\mathbb{R}$, such that F is AC_* on A for every $A\in\mathcal{A}$. By Baire's theorem (3A3G or 4A2Ma), applied to the locally compact Polish space V, $V\setminus\overline{A}$ cannot be dense in V for every $A\in\mathcal{A}$, so there are an $A\in\mathcal{A}$ and a bounded open interval $\tilde{J}$ such that $\emptyset\neq V\cap\tilde{J}\subseteq\overline{A}$. Set $K=\overline{\tilde{J}\cap A}$; by 483Pc, F is AC_* on K, and $V\cap\tilde{J}\subseteq K$. Because V has no isolated points, $V\cap\tilde{J}$ is infinite, so, setting $a^*=\min K$ and $b^*=\max K$, $V\cap\,]a^*,b^*[$ is non-empty.

By 483Q, there is a Lebesgue integrable function $g:\mathbb{R}\to\mathbb{R}$ such that

$$F(x)=F(a^*)+\int_{a^*}^x g+\sum_{I\in\mathcal{I}_0,I\subseteq[a^*,x]}F(\sup I)-F(\inf I)$$

for every $x\in K$, where $\mathcal{I}_0$ is the family of non-empty bounded open intervals, disjoint from K, with endpoints in K, and $\sum_{I\in\mathcal{I}_0}\omega(F\restriction I)$ is finite. Since every member of $\mathcal{I}_0$ is disjoint from V, it is included in some member of $\mathcal{I}^*$ and belongs to $\mathcal{J}$, so $F(\sup I)-F(\inf I)=\int f\times\chi I$ for every $I\in\mathcal{I}_0$. If $I\in\mathcal{I}_0$, then

$$\begin{aligned}\|f\times\chi I\|_H&=\sup_{C\in\mathcal{C}}|\int f\times\chi I\times\chi C|=\sup_{C\in\mathcal{C},C\subseteq I}|\int f\times\chi C|\\&=\sup_{C\in\mathcal{C},C\subseteq I}F(\sup C)-F(\inf C)=\omega(F\restriction I)\end{aligned}$$

because every non-empty subinterval of I belongs to $\mathcal{J}$. So $\sum_{I\in\mathcal{I}_0}\|f\times\chi I\|_H$ is finite, and $f\times\chi H$ is Henstock integrable, where $H=\bigcup\mathcal{I}_0$, by 483N. Moreover, if $x\in K$, then

$$\begin{aligned}\int_{a^*}^x f\times\chi H&=\int f\times\chi(\bigcup\{I:I\in\mathcal{I}_0,\,I\subseteq[a^*,x]\})\\&=\sum_{I\in\mathcal{I}_0,I\subseteq[a^*,x]}\int f\times\chi I=\sum_{I\in\mathcal{I}_0,I\subseteq[a^*,x]}F(\sup I)-F(\inf I).\end{aligned}$$

But this means that if $y\in[a^*,b^*]$, and $x=\max(K\cap[a^*,y])$, so that $]x,y[\subseteq H$, then

$$\begin{aligned}F(y)&=F(x)+F(y)-F(x)\\&=F(a^*)+\int_{a^*}^x g+\sum_{I\in\mathcal{I}_0,I\subseteq[a^*,x]}(F(\sup I)-F(\inf I))+\int f\times\chi\,]x,y[\\&=F(a^*)+\int g\times\chi(K\cap[a^*,y[)+\int_{a^*}^x f\times\chi H+\int f\times\chi\,]x,y[\\&=F(a^*)+\int_{-\infty}^y h\end{aligned}$$

where $h=f\times\chi H+g\times\chi K$ is Henstock integrable because $f\times\chi H$ is Henstock integrable and $g\times\chi K$ is Lebesgue integrable.

Accordingly, if C is any non-empty subinterval of $[a^*,b^*]$, $F(\sup C)-F(\inf C)=\int h\times\chi C$. But we also know that $\frac{d}{dy}\int_{-\infty}^y h=h(y)$ for almost every y, by 483I. So $F'(y)$ is defined and equal to $h(y)$ for almost every $y\in[a^*,b^*]$, and $h=f$ a.e. on $[a^*,b^*]$. This means that $F(\sup C)-F(\inf C)=\int f\times\chi C$ for any non-empty subinterval C of $[a^*,b^*]$, and $]a^*,b^*[\,\in\mathcal{I}$. But $]a^*,b^*[$ meets V, so this is impossible. **X**

(iv) This contradiction shows that $\mathbb{R}\in\mathcal{I}$ and that F is an indefinite Henstock integral, as required.

483X Basic exercises >(a) Let $[a,b]\subseteq\mathbb{R}$ be a non-empty closed interval, and let I_μ be the gauge integral on $[a,b]$ defined from Lebesgue measure and the tagged-partition structure defined in 481J. Show that, for $f:\mathbb{R}\to\mathbb{R}$, $I_\mu(f\restriction[a,b])=\int f\times\chi[a,b]$ if either is defined.

>(b) Extract ideas from the proofs of 482G and 482H to give a direct proof of 483B(c)-(d).

(c) Set $f(0) = 0$ and $f(x) = \frac{\sin x}{x}$ for other real x. Show that f is Henstock integrable, and that $\int_0^\infty f = \frac{\pi}{2}$. (*Hint*: 283Da.)

(d) Set $f(x) = \frac{1}{x}\cos(\frac{1}{x^2})$ for $0 < x \leq 1$, 0 for other real x. Show that f is Henstock integrable but not Lebesgue integrable. (*Hint*: by considering $\frac{d}{dx}(x^2 \sin\frac{1}{x^2})$, show that $\lim_{a\downarrow 0}\int_a^1 f$ is defined.)

(e) Let $f : \mathbb{R} \to \mathbb{R}$ be a Henstock integrable function. Show that there is a finitely additive functional $\lambda : \mathcal{P}\mathbb{R} \to \mathbb{R}$ such that for every $\epsilon > 0$ there are a gauge $\delta \in \Delta$ and a Radon measure ν on $\mathbb{R}$ such that $\nu\mathbb{R} \leq \epsilon$ and $|S_{\boldsymbol{t}}(f,\mu) - \lambda W_{\boldsymbol{t}}| \leq \nu W_{\boldsymbol{t}}$ for every δ-fine $\boldsymbol{t} \in T$.

(f) Let $f : \mathbb{R} \to \mathbb{R}$ be a Henstock integrable function. Show that $\bigcup\{G : G \subseteq \mathbb{R} \text{ is open, } f \text{ is Lebesgue integrable over } G\}$ is dense. (*Hint*: 483G.)

>(g) Let $f : \mathbb{R} \to \mathbb{R}$ be a Henstock integrable function and F its indefinite Henstock integral. Show that f is Lebesgue integrable iff F is of bounded variation on $\mathbb{R}$. (*Hint*: 224I.)

>(h) Let $F : \mathbb{R} \to \mathbb{R}$ be a continuous function such that $\lim_{x\to-\infty} F(x) = 0$, $\lim_{x\to\infty} F(x)$ is defined in $\mathbb{R}$, and $F'(x)$ is defined for all but countably many $x \in \mathbb{R}$. Show that F is the indefinite Henstock integral of any function $f : \mathbb{R} \to \mathbb{R}$ extending F'. (*Hint*: in 483J, take F_1 and F_2 differing from F by saltus functions.)

(i) Let $f : \mathbb{R} \to \mathbb{R}$ be a Henstock integrable function, and $\langle I_n\rangle_{n\in\mathbb{N}}$ a disjoint sequence of intervals in $\mathbb{R}$. Show that $\lim_{n\to\infty} \|f \times \chi I_n\|_H = 0$.

(j) Show that HL^1 is not a Banach space. (*Hint*: there is a continuous function which is nowhere differentiable.)

>(k) Use 483N to replace half of the proof of 483Bd.

(l) Let U be a linear subspace of $\mathbb{R}^{\mathbb{R}}$ and $\phi : U \to \mathbb{R}$ a linear functional such that (i) $f \in U$ and $\phi f = \int f d\mu$ for every Lebesgue integrable function $f : \mathbb{R} \to \mathbb{R}$ (ii) $f \times \chi C \in U$ whenever $f \in U$ and $C \in \mathcal{C}$ (iii) whenever $f \in U$ and $\mathcal{I}$ is a disjoint family of non-empty open intervals such that $\sum_{I\in\mathcal{I}} \sup_{C\subseteq I, C\in\mathcal{C}} |\phi(f \times \chi C)| < \infty$, then $f \times \chi(\bigcup\mathcal{I}) \in U$ and $\phi(f \times \chi(\bigcup\mathcal{I})) = \sum_{I\in\mathcal{I}} \phi(f \times \chi I)$. Show that if $f : \mathbb{R} \to \mathbb{R}$ is any Henstock integrable function, then $f \in U$ and $\phi(f) = \int f$. (*Hint*: use the argument of part (b) of the proof of 483R.)

(m) Let $F : \mathbb{R} \to \mathbb{R}$ be such that D^*F and D_*F are both finite everywhere. Show that $F(b) - F(a) = \int D^*F \times \chi[a,b]$ whenever $a \leq b$ in $\mathbb{R}$.

>(n) Let ν be any Radon measure on $\mathbb{R}$, and let I_ν be the gauge integral defined from ν and the tagged-partition structure of 481K and this section.

(i) Show that if $I_\nu(f)$ is defined, then f is $\operatorname{dom}\nu$-measurable.

(ii) Show that if $f : \mathbb{R} \to \mathbb{R}$ is such that $\int f d\nu$ is defined in $\mathbb{R}$, then $I_\nu(f)$ is defined and equal to $\int f d\nu$.

(iii) Suppose that $f : \mathbb{R} \to \mathbb{R}$ is a function, and $\alpha \in]-\infty,\infty]$. Show that $I_\nu(f \times \chi]-\infty,\alpha[) = \lim_{\beta\uparrow\alpha} I_\nu(f \times \chi]-\infty,\beta[)$ if either is defined in $\mathbb{R}$.

(iv) Show that if $I_\nu(f)$ is defined, then there is a countable cover of $\mathbb{R}$ by compact sets K such that $\int_K |f| d\nu < \infty$.

(o) (Bongiorno di Piazza & Preiss 00) Let $\mathcal{C}$ be the set of non-empty subintervals of a closed interval $[a,b] \subseteq \mathbb{R}$, and T the straightforward set of tagged partitions generated by $[a,b] \times \mathcal{C}$. Let Δ be the set of neighbourhood gauges on $[a,b]$. For $\alpha \geq 0$ set

$$T_\alpha = \{\boldsymbol{t} : \boldsymbol{t} \in T, \textstyle\sum_{(x,C)\in\boldsymbol{t}} \rho(x,C) \leq \alpha\},$$

writing $\rho(x,C) = \inf_{y\in C} |x - y|$ as usual. Show that T_α is compatible with Δ and $\mathfrak{R} = \{\{\emptyset\}\}$ in the sense of 481F. Show that if I_α is the gauge integral defined from $[a,b]$, T_α, Δ, $\mathfrak{R}$ and Lebesgue measure, then I_α extends the ordinary Lebesgue integral and $I_\alpha(F') = F(b) - F(a)$ whenever $F : [a,b] \to \mathbb{R}$ is differentiable.

483Y Further exercises (a) Let us say that a **Lebesgue measurable neighbourhood gauge** on $\mathbb{R}$ is a neighbourhood gauge of the form $\{(x,A) : x \in \mathbb{R},\ A \subseteq]x-\eta_x, x+\eta_x[\}$ where $x \mapsto \eta_x$ is a Lebesgue measurable function from $\mathbb{R}$ to $[0,\infty[$. Let $\tilde{\Delta}$ be the set of Lebesgue measurable neighbourhood gauges. Show that the gauge integral defined by the tagged-partition structure $(\mathbb{R}, T, \tilde{\Delta}, \Re)$ and μ is the Henstock integral.

(b) Show that if $\Delta_0 \subseteq \Delta$ is any set of cardinal at most $\mathfrak{c}$, then the gauge integral defined by $(\mathbb{R}, T, \Delta_0, \Re)$ and μ does not extend the Lebesgue integral, so is not the Henstock integral.

(c) Let $f : \mathbb{R} \to \mathbb{R}$ be a Henstock integrable function with indefinite Henstock integral F, and ν a totally finite Radon measure on $\mathbb{R}$. Set $G(x) = \nu\,]-\infty, x]$ for $x \in \mathbb{R}$. Show that $f \times G$ is Henstock integrable, with indefinite Henstock integral H, where $H(x) = F(x)G(x) - \int_{]-\infty,x]} F\,d\nu$ for $x \in \mathbb{R}$.

(d) Let $f : \mathbb{R} \to \mathbb{R}$ be a Henstock integrable function, and $G : \mathbb{R} \to \mathbb{R}$ a function of bounded variation. Show that $f \times G$ is Henstock integrable, and

$$\left|\int f \times G\right| \leq (\lim_{x\to\infty} |G(x)| + \operatorname{Var}_{\mathbb{R}} G) \sup_{x\in\mathbb{R}} \left|\int_{-\infty}^{x} f\right|.$$

(Compare 224J.)

(e) Let $f : \mathbb{R} \to \mathbb{R}$ be a Henstock integrable function and $g : \mathbb{R} \to \mathbb{R}$ a Lebesgue integrable function; let F and G be their indefinite (Henstock) integrals. Show that $\int f \times G + \int g \times F\,d\mu$ is defined and equal to $\lim_{x\to\infty} F(x)G(x)$.

(f) Let $f : \mathbb{R} \to \mathbb{R}$ be a function. Show that f is Lebesgue integrable iff $f \times g$ is Henstock integrable for every bounded continuous function $g : \mathbb{R} \to \mathbb{R}$.

(g) Let V be a Banach space and $f : \mathbb{R} \to V$ a function. For $\boldsymbol{t} \in T$, set $S_{\boldsymbol{t}}(f,\mu) = \sum_{(x,C)\in\boldsymbol{t}} f(x)\mu C$. We say that f is **Henstock integrable**, with **Henstock integral** $u = \int f \in V$, if $u = \lim_{\boldsymbol{t}\to\mathcal{F}(T,\Delta,\Re)} S_{\boldsymbol{t}}(f,\mu)$.

(i) Show that the set $\mathcal{HL}^1_V$ of Henstock integrable functions from $\mathbb{R}$ to V is a linear subspace of $V^{\mathbb{R}}$ including the space $\mathcal{L}^1_V$ of Bochner integrable functions (253Yf), and that $\int : \mathcal{HL}^1_V \to V$ is a linear operator extending the Bochner integral.

(ii) Show that if $f : \mathbb{R} \to V$ is Henstock integrable, so is $f \times \chi C$ for every interval $C \subseteq \mathbb{R}$, and that $(a,b) \mapsto \int f \times \chi[a,b]$ is continuous. Set $\|f\|_H = \sup_{C\in\mathcal{C}} \|\int f \times \chi C\|$.

(iii) Show that if $\mathcal{I}$ is a disjoint family of open intervals in $\mathbb{R}$, and $f : \mathbb{R} \to V$ is such that $f \times \chi I \in \mathcal{HL}^1_V$ for every $I \in \mathcal{I}$ and $\sum_{I\in\mathcal{I}} \|f \times \chi I\|_H$ is finite, then $\int f \times \chi(\bigcup \mathcal{I})$ is defined and equal to $\sum_{I\in\mathcal{I}} \int f \times \chi I$.

(iv) Define $f : \mathbb{R} \to \ell^\infty([0,1])$ by setting $f(x) = \chi([0,1] \cap]-\infty, x])$ for $x \in \mathbb{R}$. Show that f is Henstock integrable, but that if $F(x) = \int f \times \chi\,]-\infty, x[$ for $x \in \mathbb{R}$, then $\lim_{y\to x} \frac{1}{y-x}(F(y) - F(x))$ is not defined in $\ell^\infty([0,1])$ for any $x \in [0,1]$.

483 Notes and comments I hope that the brief account here (largely taken from Gordon 94) will give an idea of the extraordinary power of gauge integrals. While what I am calling the 'Henstock integral', regarded as a linear functional on a space of real functions, was constructed long ago by Perron and Denjoy, the gauge integral approach makes it far more accessible, and gives clear pathways to corresponding Stieltjes and vector integrals (483Xn, 483Yg).

Starting from our position in the fourth volume of a book on measure theory, it is natural to try to describe the Henstock integral in terms of the Lebesgue integral, as in 483C (they agree on non-negative functions) and 483Xl (offering an extension process to generate the Henstock integral from the Lebesgue integral); on the way, we see that Henstock integrable functions are necessarily Lebesgue integrable over many intervals (483Xf). Alternatively, we can set out to understand indefinite Henstock integrals and their derivatives, just as Lebesgue integrable functions can be characterized as almost everywhere equal to derivatives of absolutely continuous functions (222E, 225E), because if f is Henstock integrable then it is equal almost everywhere to the derivative of its indefinite integral (483I). Any differentiable function (indeed, any continuous function differentiable except on a countable set) is an indefinite Henstock integral (483Xh). Recall that the Cantor

function (134H) is continuous and differentiable almost everywhere but is not an indefinite integral, so we have to look for a characterization which can exclude such cases. For this we have to work quite hard, but we find that 'ACG$_*$ functions' are the appropriate class (483R).

Gauge integrals are good at integrating derivatives (see 483Xh), but bad at integrating over subspaces. Even to show that $f \times \chi[0,\infty[$ is Henstock integrable whenever f is (482Bc) involves us in some unexpected manoeuvres. I give an argument which is designed to show off the general theory of §482, and I recommend you to look for short cuts (483Xb), but any method must depend on careful examination of the exact classes $\mathcal{C}$ and $\mathfrak{R}$ chosen for the definition of the integral. We do however have a new kind of convergence theorem in 482H and 483N.

One of the incidental strengths of the Henstock integral is that it includes the improper Riemann integral (483Bd, 483Xc); so that, for instance, Carleson's theorem (286U) can be written in the form

$$\hat{f}(y) = \tfrac{1}{\sqrt{2\pi}} \text{⨍} e^{-ixy} f(x)dx \text{ for almost every } y$$

if $f : \mathbb{R} \to \mathbb{C}$ is square-integrable. But to represent the many formulae of the type $\lim_{a\to\infty} \int_{-a}^{a} f$ in §283 (e.g., 283F, 283I and 283L) directly in the form $I_\mu(f)$ we need to change $\mathfrak{R}$, as in 481L or 481Xc.

484 The Pfeffer integral

I give brief notes on what seems at present to be the most interesting of the multi-dimensional versions of the Henstock integral, leading to Pfeffer's Divergence Theorem (484N).

484A Notation This section will depend heavily on Chapter 47, and will use much of the same notation. $r \geq 2$ will be a fixed integer, and μ will be Lebesgue measure on $\mathbb{R}^r$, while μ_{r-1} is Lebesgue measure on $\mathbb{R}^{r-1}$. As in §§473-475, let ν be 'normalized' $(r-1)$-dimensional Hausdorff outer measure on $\mathbb{R}^r$, as described in §265; that is, $\nu = 2^{-r+1}\beta_{r-1}\mu_{H,r-1}$, where $\mu_{H,r-1}$ is $r-1$-dimensional Hausdorff measure on $\mathbb{R}^r$ as described in §264, and

$$\begin{aligned}\beta_{r-1} &= \frac{2^{2k}k!\pi^{k-1}}{(2k)!} \text{ if } r = 2k \text{ is even},\\ &= \frac{\pi^k}{k!} \text{ if } r = 2k+1 \text{ is odd}\end{aligned}$$

is the Lebesgue measure of a ball of diameter 1 in $\mathbb{R}^{r-1}$ (264I). For this section only, let us say that a subset of $\mathbb{R}^r$ is **thin** if it is of the form $\bigcup_{n\in\mathbb{N}} A_n$ where $\nu^* A_n$ is finite for every n. Note that by 471L, $\mu A = 0$ for every thin set A. For $A \subseteq \mathbb{R}^r$, write ∂A for its ordinary topological boundary. If $x \in \mathbb{R}^r$ and $\epsilon > 0$, $B(x,\epsilon)$ will be the closed ball $\{y : \|y - x\| \leq \epsilon\}$.

I will use the term **dyadic cube** for sets of the form $\prod_{i<r} [2^{-m}k_i, 2^{-m}(k_i+1)[$ where $m, k_0, \ldots, k_{r-1} \in \mathbb{Z}$; write $\mathcal{D}$ for the set of dyadic cubes in $\mathbb{R}^r$. Note that if $D, D' \in \mathcal{D}$, either $D \subseteq D'$ or $D' \subseteq D$ or $D \cap D' = \emptyset$; so if $\mathcal{D}_0 \subseteq \mathcal{D}$, the maximal members of $\mathcal{D}_0$ are disjoint.

It will be helpful to have an abbreviation for the following expression: set

$$\alpha^* = \min(\frac{1}{r^{r/2}}, \frac{2^{r-2}}{r\beta_r^{(r-1)/r}}).$$

(As will become apparent, the actual value of this constant is of no importance; but the strict logic of the arguments below depends on α^* being small enough.)

As in §475, I write int$^*A$, cl$^*A$ and ∂^*A for the essential interior, essential closure and essential boundary of a set $A \subseteq \mathbb{R}^r$ (475B). Recall that a set $A \subseteq \mathbb{R}^r$ has finite perimeter in the sense of 474D iff $\nu(\partial^* A)$ is finite, and then

$$\nu(\partial^* A) = \lambda_A^\partial(\mathbb{R}^r) = \operatorname{per} A$$

is the perimeter of A (475M); we shall also need to remember that A is necessarily Lebesgue measurable.

$\mathcal{C}$ will be the family of subsets of $\mathbb{R}^r$ with locally finite perimeter, and $\mathcal{V}$ the family of bounded sets in $\mathcal{C}$, that is, the family of bounded sets with bounded perimeter. Note that $\mathcal{C}$ is an algebra of subsets of $\mathbb{R}^r$ (475Ma), and that $\mathcal{V}$ is an ideal in $\mathcal{C}$.

484B Theorem (Tamanini & Giacomelli 89) Let $E \subseteq \mathbb{R}^r$ be a Lebesgue measurable set of finite measure and perimeter, and $\epsilon > 0$. Then there is a Lebesgue measurable set $G \subseteq E$ such that $\operatorname{per} G \leq \operatorname{per} E$, $\mu(E \setminus G) \leq \epsilon$ and $\operatorname{cl}^*G = \overline{G}$.

proof (Pfeffer 91b) **(a)** Set $\alpha = \frac{1}{\epsilon} \operatorname{per} E$. For measurable sets $G \subseteq E$ set $q(G) = \operatorname{per} G - \alpha\mu G$. Then there is a self-supporting measurable set $G \subseteq E$ such that $q(G) \leq q(G')$ whenever $G' \subseteq E$ is measurable.

P Write Σ for the family of Lebesgue measurable subsets of $\mathbb{R}^r$; give Σ the topology of convergence in measure defined by the pseudometrics $\rho_H(G, G') = \mu((G \triangle G') \cap H)$ for measurable sets H of finite measure (cf. 474S). Extend q to Σ by setting $q(G) = \operatorname{per}(E \cap G) - \alpha\mu(E \cap G)$ for every $G \in \Sigma$. Because $\operatorname{per} : \Sigma \to [0, \infty]$ is lower semi-continuous for the topology of convergence in measure (474Sa), and $G \mapsto E \cap G$, $G \mapsto \mu(E \cap G)$ are continuous, $q : \Sigma \to [0, \infty[$ is lower semi-continuous (4A2B(d-ii)). Next, $\mathcal{K} = \{G : G \in \Sigma, \operatorname{per} G \leq \operatorname{per} E\}$ is compact (474Sb), while $\mathcal{L} = \{G : \mu(G \setminus E) = 0\}$ is closed, so there is an $G_0 \in \mathcal{L} \cap \mathcal{K}$ such that $q(G_0) = \inf_{G \in \mathcal{L} \cap \mathcal{K}} q(G)$ (4A2Gk). Since $G_0 \in \mathcal{L}$, $\operatorname{per}(G_0 \cap E) = \operatorname{per}(G_0)$ and $\mu(G_0 \cap E) = \mu G_0$, so we may suppose that $G_0 \subseteq E$. Moreover, there is a self-supporting set $G \subseteq G_0$ such that $G_0 \setminus G$ is negligible (414F), and we still have $q(G) = q(G_0)$. Of course $q(G) \leq q(E)$, just because $E \in \mathcal{L} \cap \mathcal{K}$.

? If there is a measurable set $G' \subseteq E$ such that $q(G') < q(G)$, then

$$\operatorname{per} G' = q(G') + \alpha\mu G' \leq q(E) + \alpha\mu E = \operatorname{per} E,$$

so $G' \in \mathcal{K}$; but this means that $G' \in \mathcal{L} \cap \mathcal{K}$ and $q(G) = q(G_0) \leq q(G')$. **X** So G has the required properties. **Q**

(b) Since $q(G) \leq q(E)$, we must have

$$\operatorname{per} G = q(G) + \alpha\mu G \leq q(E) + \alpha\mu E = \operatorname{per} E$$

(just as in the last part of the proof of (a)). Also $\operatorname{per} G + \alpha\mu(E \setminus G) \leq \operatorname{per} E$, so $\mu(E \setminus G) \leq \epsilon$.

(c) Next, $\overline{G} \subseteq \operatorname{cl}^*G$. **P** Let $x \in \overline{G}$. For every $t > 0$, set $U_t = \{y : \|y - x\| < t\}$; then $q(G \setminus U_t) \leq q(G)$. Now

$$\begin{aligned}
\operatorname{per}(G \cap U_t) + \operatorname{per}(G \setminus U_t) &= \nu(\partial^*(G \cap U_t)) + \nu(\partial^*(G \setminus U_t)) \\
&\leq \nu(\partial^*G \cap U_t) + \nu(\operatorname{cl}^*G \cap \partial U_t) \\
&\qquad + \nu(\partial^*G \setminus U_t) + \nu(\operatorname{cl}^*G \cap \partial U_t)
\end{aligned}$$

(475Cf, because $\partial(\mathbb{R}^r \setminus U_t) = \partial U_t$))

$$= \nu(\partial^*G) + 2\nu(\operatorname{cl}^*G \cap \partial U_t) = \operatorname{per} G + 2\nu(G \cap \partial U_t)$$

for almost every $t > 0$, because

$$\int_0^\infty \nu((G \triangle \operatorname{cl}^*G) \cap \partial U_t)dt = \mu(G \triangle \operatorname{cl}^*G) = 0$$

(265G). So, for almost every t,

$$\mu(G \cap U_t)^{(r-1)/r} \leq \operatorname{per}(G \cap U_t)$$

(474La)

$$\begin{aligned}
&\leq \operatorname{per} G + 2\nu(G \cap \partial U_t) - \operatorname{per}(G \setminus U_t) \\
&= q(G) + \alpha\mu(G \cap U_t) + 2\nu(G \cap \partial U_t) - q(G \setminus U_t) \\
&\leq \alpha\mu(G \cap U_t) + 2\nu(G \cap \partial U_t)
\end{aligned}$$

because $q(G)$ is minimal.

? Suppose, if possible, that $x \notin \operatorname{cl}^*G$. Take $\beta > 0$ such that $2\beta < \frac{1}{r}\beta^{(r-1)/r}$. Then there is some $\gamma > 0$ such that $\mu(G \cap U_t) \leq \beta t^r$ for every $t \in]0, \gamma]$, and we may suppose that $2\beta < \frac{1}{r}\beta^{(r-1)/r} - \frac{1}{r+1}\alpha\gamma$. In this case, for almost every $t \in]0, \gamma]$,

$$\nu(G\cap\partial U_t)\geq\tfrac{1}{2}(\beta^{(r-1)/r}t^{r-1}-\alpha t^r),$$

so

$$\beta\gamma^r\geq\mu(G\cap U_\gamma)=\textstyle\int_0^\gamma\nu(G\cap\partial U_t)dt\geq\frac{1}{2}\big(\frac{\beta^{(r-1)/r}}{r}\gamma^r-\frac{\alpha}{r+1}\gamma^{r+1}\big)$$

and

$$2\beta\geq\tfrac{1}{r}\beta^{(r-1)/r}-\tfrac{1}{r+1}\alpha\gamma>2\beta,$$

which is absurd. **X**

Thus $x\in\text{cl}^*G$. As x is arbitrary, $\overline{G}\subseteq\text{cl}^*G$. **Q**

Since we certainly have $\text{cl}^*G\subseteq\overline{G}$, this G serves.

484C Lemma Let $E\in\mathcal{V}$ and $l\in\mathbb{N}$ be such that $\max(\text{per}\,E,\text{diam}\,E)\leq l$. Then E is expressible as $\bigcup_{i<n}E_i$ where $\langle E_i\rangle_{i<n}$ is disjoint, $\text{per}\,E_i\leq 1$ for each $i<n$ and n is at most $2^r(l+2)^r(4r(4l^2+1))^{r/(r-1)}+2^{r+2}l^2$.

proof For $D\in\mathcal{D}$, write $\mathcal{D}_D$ for $\{D':D'\in\mathcal{D},\,D'\subseteq D,\,\text{diam}\,D'=\frac{1}{2}\text{diam}\,D\}$, the family of the 2^r dyadic subcubes of D at the next level down.

(a) If $l\leq 1$ the result is trivial, so let us suppose that $l\geq 2$. Let $m\in\mathbb{N}$ be minimal subject to $4r(4l^2+1)\leq 2^{m(r-1)}$, so that $2^m\leq 2(4r(4l^2+1))^{1/(r-1)}$. Then we can cover E by a family $\mathcal{L}_0$ of dyadic cubes of side 2^{-m} with

$$\#(\mathcal{L}_0)\leq(2^ml+2)^r\leq 2^r(l+2)^r(4r(4l^2+1))^{r/(r-1)}.$$

(b) Let $\mathcal{L}_1$ be the set of those $D\in\mathcal{D}$ such that D is included in some member of $\mathcal{L}_0$ and $\lfloor 2\nu(D'\cap\partial^*E)\rfloor<\lfloor 2\nu(D\cap\partial^*E)\rfloor$ for every $D'\in\mathcal{D}_D$. Then $\#(\mathcal{L}_1)\leq(2l)^2$. **P** I show by induction on k that if $D_0\in\mathcal{D}$ and $\lfloor 2\nu(D\cap\partial^*E)\rfloor=k$ then $\#(\{D:D\in\mathcal{L}_1,\,D\subseteq D_0\}\leq k^2$. For $k=0$ this is trivial. For the inductive step to $k>0$, given that $\lfloor 2\nu(D_0\cap\partial^*E)\rfloor=k$, let $\mathcal{L}_1'$ be the set of maximal elements in

$$\{D:D\in\mathcal{L}_1,\,D\subseteq D_0,\,\lfloor 2\nu(D\cap\partial^*E)\rfloor<k\}.$$

Now there can be at most one member D of $\mathcal{L}_1$ included in D_0 and with $\lfloor 2\nu(D\cap\partial^*E)\rfloor\geq k$. So

$$\begin{aligned}\#(\{D:D\in\mathcal{L}_1,\,D\subseteq D_0\})&\leq 1+\sum_{D_1\in\mathcal{L}_1'}\#(\{D:D\in\mathcal{L}_1,\,D\subseteq D_1\})\\&\leq 1+\sum_{D_1\in\mathcal{L}_1'}(\lfloor 2\nu(D_1\cap\partial^*E)\rfloor)^2\end{aligned}$$

(by the inductive hypothesis)

$$\leq(\lfloor 2\nu(D_0\cap\partial^*E)\rfloor)^2$$

(because $(\lfloor\alpha\rfloor)^2+(\lfloor\beta\rfloor)^2<(\lfloor\alpha+\beta\rfloor)^2$ whenever $\alpha,\,\beta\geq 0$ and $\max(\lfloor\alpha\rfloor,\lfloor\beta\rfloor)<\lfloor\alpha+\beta\rfloor$))

$$\leq k^2.$$

So the induction proceeds. Taking $k=2l$, we have the result. **Q**

(c) Set $\mathcal{L}_2=\mathcal{L}_0\cup\bigcup\{\mathcal{D}_D:D\in\mathcal{L}_1\}$. For $D\in\mathcal{L}_2$, set $\tilde{D}=D\setminus\bigcup\{D':D'\in\mathcal{L}_1,\,D'\subseteq D\}$, and consider $\mathcal{K}=\{\tilde{D}:D\in\mathcal{L}_2\}$, so that

$$\begin{aligned}\#(\mathcal{K})\leq\#(\mathcal{L}_2)&\leq\#(\mathcal{L}_0)+2^r\#(\mathcal{L}_1)\\&\leq 2^r(l+2)^r(4r(4l^2+1))^{r/(r-1)}+2^{r+2}l^2.\end{aligned}$$

(d)(i) $\bigcup\mathcal{K}\supseteq E$. **P** If $x\in E$, there is a smallest member D of $\mathcal{L}_2$ containing it, because certainly $x\in\bigcup\mathcal{L}_0$. But now x cannot belong to any member of $\mathcal{L}_1$ included in D, so $x\in\tilde{D}$. **Q**

(ii) $\mathcal{K}$ is disjoint. **P** If D_1, $D_2 \in \mathcal{L}_2$ are disjoint, then of course $\tilde{D}_1 \cap \tilde{D}_2 = \emptyset$. If $D_1 \subset D_2$, then $D_1 \notin \mathcal{L}_0$, so there is a $D \in \mathcal{L}_1$ such that $D_1 \in \mathcal{D}_D$; in this case $D \subseteq D_2$ so $\tilde{D}_2 \subseteq D_2 \setminus D$ is disjoint from D_1. **Q**

(iii) $\nu(D \cap \partial^* E) \leq \frac{1}{2}$ for every $D \in \mathcal{K}$. **P?** If $D_0 \in \mathcal{L}_2$ and $\nu(\tilde{D}_0 \cap \partial^* E) > \frac{1}{2}$, set $j = \lfloor 2\nu(D_0 \cap \partial^* E) \rfloor \geq 1$. Given that $D_i \in \mathcal{D}$ is included in D_0 and $\lfloor 2\nu(D_i \cap \partial^* E) \rfloor = j$, then $\nu((D_0 \setminus D_i) \cap \partial^* E) < \frac{1}{2}$, so $\tilde{D}_0 \cap D_i$ is non-empty and $D_i \notin \mathcal{L}_1$. There must therefore be a $D_{i+1} \in \mathcal{D}_{D_i}$ such that $\lfloor 2\nu(D_{i+1} \cap \partial^* E) \rfloor = j$. Thus we have a strictly decreasing sequence $\langle D_i \rangle_{i \in \mathbb{N}}$ in $\mathcal{D}$ such that $\nu(D_i \cap \partial^* E) \geq j$ for every i. But (because $\operatorname{per} E$ is finite) this means that, writing x for the unique member of $\bigcap_{i \in \mathbb{N}} \overline{D}_i$, $\nu\{x\} \geq j$, which is absurd. **X** **Q**

(iv) $\operatorname{per}(D \cap E) \leq 1$ for every $D \in \mathcal{K}$. **P** If $D \in \mathcal{L}_2$,

$$\nu(\partial \tilde{D}) \leq \nu(\partial D) + \textstyle\sum_{D' \in \mathcal{L}_1} \nu(\partial D') \leq 2r(4l^2+1)2^{-m(r-1)} \leq \frac{1}{2}$$

by the choice of m. So

$$\operatorname{per}(D \cap E) \leq \nu(\partial D) + \nu(D \cap \partial^* E) \leq \tfrac{1}{2} + \tfrac{1}{2} = 1$$

by 475Cf. **Q**

(e) So if we take $\langle E_i \rangle_{i<n}$ to be an enumeration of $\{E \cap D : D \in \mathcal{K}\}$, we shall have the required result.

484D Definitions The gauge integrals of this section will be based on the following residual families. Let H be the family of strictly positive sequences $\eta = \langle \eta(i) \rangle_{i \in \mathbb{N}}$ in $\mathbb{R}$. For $\eta \in \mathrm{H}$, write $\mathcal{M}_\eta$ for the set of disjoint sequences $\langle E_i \rangle_{i \in \mathbb{N}}$ of measurable subsets of $\mathbb{R}^r$ such that $\mu E_i \leq \eta(i)$ and $\operatorname{per} E_i \leq 1$ for every $i \in \mathbb{N}$, and E_i is empty for all but finitely many i. Let $\mathcal{R}_\eta$ be the set of unions of members of $\mathcal{M}_\eta$. Next, for $V \in \mathcal{V}$ and $\eta \in \mathrm{H}$, set $\mathcal{R}_\eta^{(V)} = \{R : R \subseteq \mathbb{R}^r,\ R \cap V \in \mathcal{R}_\eta\}$; finally, set $\mathfrak{R} = \{\mathcal{R}_\eta^{(V)} : V \in \mathcal{V},\ \eta \in \mathrm{H}\}$.

484E Lemma (a)(i) For every $\mathcal{R} \in \mathfrak{R}$, there is an $\eta \in \mathrm{H}$ such that $\mathcal{R}_\eta \subseteq \mathcal{R}$.

(ii) If $\mathcal{R} \in \mathfrak{R}$ and $C \in \mathcal{C}$, there is an $\mathcal{R}' \in \mathfrak{R}$ such that $C \cap R \in \mathcal{R}$ whenever $R \in \mathcal{R}'$.

(b)(i) If $\eta \in \mathrm{H}$ and $\gamma \geq 0$, there is an $\epsilon > 0$ such that $R \in \mathcal{R}_\eta$ whenever $\mu R \leq \epsilon$, $\operatorname{diam} R \leq \gamma$ and $\operatorname{per} R \leq \gamma$.

(ii) If $\mathcal{R} \in \mathfrak{R}$ and $\gamma \geq 0$, there is an $\epsilon > 0$ such that $R \in \mathcal{R}$ whenever $\mu R \leq \epsilon$ and $\operatorname{per} R \leq \gamma$.

(c) If $\mathcal{R} \in \mathfrak{R}$ there is an $\mathcal{R}' \in \mathfrak{R}$ such that $R \cup R' \in \mathcal{R}$ whenever R, $R' \in \mathcal{R}'$ and $R \cap R' = \emptyset$.

(d)(i) If $\eta \in \mathrm{H}$ and $A \subseteq \mathbb{R}^r$ is a thin set, then there is a set $\mathcal{D}_0 \subseteq \mathcal{D}$ such that every point of A belongs to the interior of $\bigcup \mathcal{D}_1$ for some finite $\mathcal{D}_1 \subseteq \mathcal{D}_0$, and $\bigcup \mathcal{D}_1 \in \mathcal{R}_\eta$ for every finite set $\mathcal{D}_1 \subseteq \mathcal{D}_0$.

(ii) If $\mathcal{R} \in \mathfrak{R}$ and $A \subseteq \mathbb{R}^r$ is a thin set, then there is a set $\mathcal{D}_0 \subseteq \mathcal{D}$ such that every point of A belongs to the interior of $\bigcup \mathcal{D}_1$ for some finite set $\mathcal{D}_1 \subseteq \mathcal{D}_0$, and $\bigcup \mathcal{D}_1 \in \mathcal{R}$ for every finite set $\mathcal{D}_1 \subseteq \mathcal{D}_0$.

proof (a)(i) Express $\mathcal{R}$ as $\mathcal{R}_{\eta'}^{(V)}$ where $\eta' \in \mathrm{H}$ and $V \in \mathcal{V}$. Let $l \in \mathbb{N}$ be such that $\max(\operatorname{diam} V, 1 + \operatorname{per} V) \leq l$, and take $n \geq 2^r(l+2)^r(4r(4l^2+1))^{r/(r-1)} + 2^{r+2}l^2$. Set $\eta(i) = \min\{\eta'(j) : ni \leq j < n(i+1)\}$ for every $i \in \mathbb{N}$, so that $\eta \in \mathrm{H}$. If $R \in \mathcal{R}_\eta$, express it as $\bigcup_{i \in \mathbb{N}} E_i$ where $\langle E_i \rangle_{i \in \mathbb{N}} \in \mathcal{M}_\eta$. For each i, $\max(\operatorname{diam}(E_i \cap V), \operatorname{per}(E_i \cap V)) \leq l$, so by 484C we can express $E_i \cap V$ as $\bigcup_{ni \leq j < n(i+1)} E'_j$, where $\langle E'_j \rangle_{ni \leq j < n(i+1)}$ is disjoint and $\operatorname{per} E'_j \leq 1$ for each j. Now

$$\mu E'_j \leq \mu E_i \leq \eta(i) \leq \eta'(j)$$

for $ni \leq j < n(i+1)$. Also $\{j : E'_j \neq \emptyset\}$ is finite because $\{j : E_j = \emptyset\}$ is finite. So $\langle E'_j \rangle_{j \in \mathbb{N}} \in \mathcal{M}_{\eta'}$ and $R \cap V = \bigcup_{j \in \mathbb{N}} E'_j$ belongs to $\mathcal{R}_{\eta'}$, that is, $R \in \mathcal{R}$. As R is arbitrary, $\mathcal{R}_\eta \subseteq \mathcal{R}$.

(ii) Express $\mathcal{R}$ as $\mathcal{R}_\eta^{(V)}$, where $V \in \mathcal{V}$ and $\eta \in \mathrm{H}$. By (i), there is an $\eta' \in \mathrm{H}$ such that $\mathcal{R}_{\eta'} \subseteq \mathcal{R}_\eta^{(C \cap V)}$. Set $\mathcal{R}' = \mathcal{R}_{\eta'}^{(V)} \in \mathfrak{R}$. If $R \in \mathcal{R}'$, then $R \cap V \in \mathcal{R}_{\eta'}$, so $C \cap R \cap V \in \mathcal{R}_\eta$ and $C \cap R \in \mathcal{R}$.

(b)(i) Take $l \geq \gamma$ and $n \geq 2^r(l+2)^r(4r(4l^2+1))^{r/(r-1)} + 2^{r+2}l^2$, and set $\epsilon = \min_{i<n} \eta(i)$. If $\mu R \leq \epsilon$, $\operatorname{diam} R \leq l$ and $\operatorname{per} R \leq l$, then R is expressible as $\bigcup_{i<n} E_i$ where $\langle E_i \rangle_{i<n}$ is disjoint and $\operatorname{per} E_i \leq 1$ for each $i < n$. Since $\mu E_i \leq \mu R \leq \eta(i)$ for each i, $R \in \mathcal{R}_\eta$.

(ii) Express $\mathcal{R}$ as $\mathcal{R}_\eta^{(V)}$. By (i) just above, there is an $\epsilon > 0$ such that $R \in \mathcal{R}_\eta$ whenever $\operatorname{diam} R \leq \operatorname{diam} V$, $\operatorname{per} R \leq \gamma + \operatorname{per} V$ and $\mu R \leq \epsilon$; and this ϵ serves.

(c) Express $\mathcal{R}$ as $\mathcal{R}_\eta^{(V)}$. Set $\eta'(i) = \min(\eta(2i), \eta(2i+1))$ for every i; then $\eta' \in \mathrm{H}$ and if $\langle E_i \rangle_{i\in\mathbb{N}}$, $\langle E_i' \rangle_{i\in\mathbb{N}}$ belong to $\mathcal{M}_{\eta'}$ and have disjoint unions, then $(E_0, E_0', E_1, E_1', \dots) \in \mathcal{M}_\eta$; this is enough to show that $R \cup R' \in \mathcal{R}_\eta$ whenever R, $R' \in \mathcal{R}_{\eta'}$ are disjoint, so that $R \cup R' \in \mathcal{R}$ whenever R, $R' \in \mathcal{R}_{\eta'}^{(V)}$ are disjoint.

(d)(i)($\boldsymbol{\alpha}$) We can express A as $\bigcup_{i\in\mathbb{N}} A_i$ where $\mu^*_{H,r-1} A_i < 1/2^{r+1} r$ for every i. **P** Because A is thin, it is the union of a sequence of sets of finite outer measure for ν, and therefore for $\mu_{H,r-1}$. On each of these the subspace measure is atomless (471E, 471Dg), so that the set can be dissected into finitely many sets of measure less than $1/2^{r+1}r$ (215D). **Q**

($\boldsymbol{\beta}$) For each $i \in \mathbb{N}$, we can cover A_i by a sequence $\langle A_{ij} \rangle_{j\in\mathbb{N}}$ of sets such that $\operatorname{diam} A_{ij} < \eta(i)$ for every j and $\sum_{j=0}^\infty (\operatorname{diam} A_{ij})^{r-1} < 1/2^{r+1}r$; enlarging the A_{ij} slightly if need be, we can suppose that they are all open. Now we can cover each A_{ij} by 2^r cubes $D_{ijk} \in \mathcal{D}$ in such a way that the side length of each D_{ijk} is at most the diameter of A_{ij}.

Setting $\mathcal{D}_0 = \{D_{ijk} : i,\, j \in \mathbb{N},\, k < 2^r\}$, we see that every point of A belongs to an open set A_{ij} which is covered by a finite subset of $\mathcal{D}_0$. If $\mathcal{D}_1 \subseteq \mathcal{D}_0$ is finite, let $\mathcal{D}_1'$ be the family of maximal elements of $\mathcal{D}_1$, so that $\mathcal{D}_1'$ is disjoint and $\bigcup \mathcal{D}_1' = \bigcup \mathcal{D}_1$. Express $\mathcal{D}_1'$ as $\{D_{ijk} : (i,j,k) \in I\}$ where $I \subseteq \mathbb{N}\times\mathbb{N}\times\mathbb{N}$ and $\langle D_{ijk} \rangle_{(i,j,k)\in I}$ is disjoint. Set $I_i = \{(j,k) : (i,j,k) \in I\}$ and $E_i = \bigcup_{(j,k)\in I_i} D_{ijk}$ for $i \in \mathbb{N}$. Then $\langle E_i \rangle_{i\in\mathbb{N}}$ is disjoint, $E_i = \emptyset$ for all but finitely many i, and for each $i \in \mathbb{N}$

$$\begin{aligned}
\mu E_i &\leq \sum_{j=0}^\infty \sum_{k=0}^{2^r-1} \mu D_{ijk} \leq \sum_{j=0}^\infty \sum_{k=0}^{2^r-1} (\operatorname{diam} A_{ij})^r \\
&\leq 2^r \sum_{j=0}^\infty \eta(i) (\operatorname{diam} A_{ij})^{r-1} \leq \eta(i), \\
\nu(\partial E_i) &\leq \sum_{(j,k)\in I_i} \nu(\partial D_{ijk}) \leq \sum_{j=0}^\infty \sum_{k=0}^{2^r-1} \nu(\partial D_{ijk}) \\
&\leq \sum_{j=0}^\infty \sum_{k=0}^{2^r-1} 2r (\operatorname{diam} A_{ij})^{r-1} \leq \sum_{j=0}^\infty 2^{r+1} r (\operatorname{diam} A_{ij})^{r-1} \leq 1.
\end{aligned}$$

So $\bigcup \mathcal{D}_1 = \bigcup_{i\in\mathbb{N}} E_i$ belongs to $\mathcal{R}_\eta$.

(ii) By (a-i), there is an $\eta \in \mathrm{H}$ such that $\mathcal{R}_\eta \subseteq \mathcal{R}$. By (i) here, there is a $\mathcal{D}_0 \subseteq \mathcal{D}$ such that every point of A belongs to the interior of $\bigcup \mathcal{D}_1$ for some finite $\mathcal{D}_1 \subseteq \mathcal{D}_0$, and $\bigcup \mathcal{D}_1 \in \mathcal{R}_\eta \subseteq \mathcal{R}$ for every finite set $\mathcal{D}_1 \subseteq \mathcal{D}_0$.

484F A family of tagged-partition structures For $\alpha > 0$, let $\mathcal{C}_\alpha$ be the family of those $C \in \mathcal{V}$ such that $\mu C \geq \alpha (\operatorname{diam} C)^r$ and $\alpha \operatorname{per} C \leq (\operatorname{diam} C)^{r-1}$, and let T_α be the straightforward set of tagged partitions generated by the set

$$\{(x, C) : C \in \mathcal{C}_\alpha,\, x \in \mathrm{cl}^* C\}.$$

Note that if $0 < \alpha' \leq \alpha$ then $\mathcal{C}_\alpha \subseteq \mathcal{C}_{\alpha'}$ and $T_\alpha \subseteq T_{\alpha'}$. Let Θ be the set of functions $\theta : \mathbb{R}^r \to [0, \infty[$ such that $\{x : \theta(x) = 0\}$ is thin (definition: 484A), and set $\Delta = \{\delta_\theta : \theta \in \Theta\}$, where $\delta_\theta = \{(x, A) : x \in \mathbb{R}^r,\, \theta(x) > 0,\, A \subseteq B(x, \theta(x))\}$.

Then whenever $0 < \alpha < \alpha^*$, $(\mathbb{R}^r, T_\alpha, \Delta, \mathfrak{R})$ is a tagged-partition structure allowing subdivisions, witnessed by $\mathcal{C}$.

proof (a) We had better look again at all the conditions in 481G.

(i) and (vi) really are trivial. (iv) is true because $\mathcal{C}$ is actually an algebra of sets, and (v) is true because $\mathcal{V} \subseteq \mathcal{C}$ and $\emptyset \in \mathcal{R}_\eta$ for every $\eta \in \mathrm{H}$.

For (ii), we have to observe that the union of two thin sets is thin, so that $\theta \wedge \theta' \in \Theta$ for all θ, $\theta' \in \Theta$; since $\delta_{\theta_1} \cap \delta_{\theta_2} = \delta_{\theta_1 \wedge \theta_2}$, this is all we need.

(iii)(α) follows from 484Ea: given V, $V' \in \mathcal{V}$ and η, $\eta' \in \mathrm{H}$, take $\tilde\eta$, $\tilde\eta' \in \mathrm{H}$ such that $\mathcal{R}_{\tilde\eta} \subseteq \mathcal{R}_\eta^{(V)}$ and $\mathcal{R}_{\tilde\eta'} \subseteq \mathcal{R}_{\eta'}^{(V')}$. Then $V \cup V' \in \mathcal{V}$ (475Cd) and $\mathcal{R}_\eta^{(V)} \cap \mathcal{R}_{\eta'}^{(V')} \supseteq \mathcal{R}_{\tilde\eta\wedge\tilde\eta'}^{(V\cup V'))}$. ($\beta$) is just 484Ec.

(b) Now let us turn to 481G(vii).

(i) Fix $C \in \mathcal{C}$, $\delta \in \Delta$ and $\mathcal{R} \in \mathfrak{R}$. Express δ as δ_θ where $\theta \in \Theta$. Let $\mathcal{R}' \in \mathfrak{R}$ be such that $A \cup A' \in \mathcal{R}$ whenever A, $A' \in \mathcal{R}'$ are disjoint. Express $\mathcal{R}'$ as $\mathcal{R}_\eta^{(V)}$ where $V \in \mathcal{V}$ and $\eta \in \mathrm{H}$. By 475E(b-ii), there is an $\epsilon > 0$ such that $R \in \mathcal{R}'$ whenever $\operatorname{diam} R \le \operatorname{diam} V$, $\operatorname{per} R \le 2\operatorname{per}(C \cap V)$ and $\mu R \le \epsilon$.

By 484B, there is an $E \subseteq C \cap V$ such that $\operatorname{per} E \le \operatorname{per}(C \cap V)$, $\mu((C \cap V) \setminus E) \le \epsilon$ and $\mathrm{cl}^* E = \overline{E}$. In this case, $\operatorname{diam}(C \cap V \setminus E) \le \operatorname{diam} V$ and

$$\operatorname{per}(C \cap V \setminus E) \le \operatorname{per}(C \cap V) + \operatorname{per} E \le 2\operatorname{per}(C \cap V),$$

so $C \cap V \setminus E \in \mathcal{R}'$, by the choice of ϵ. By 475E(a-ii), there is an $\mathcal{R}'' \in \mathfrak{R}$ such that $E \cap R \in \mathcal{R}'$ whenever $R \in \mathcal{R}''$.

Now consider

$$A = \{x : \theta(x) = 0\} \cup \partial^* E \cup \{x : \limsup_{\zeta \downarrow 0} \sup_{x \in G, 0 < \operatorname{diam} G \le \zeta} \tfrac{\nu^*(G \cap \partial^* E)}{(\operatorname{diam} G)^{r-1}} > 0\}.$$

Because $\operatorname{per} E < \infty$ and

$$\{x : x \in \mathbb{R}^r \setminus \partial^* E, \limsup_{\zeta \downarrow 0} \sup_{x \in G, 0 < \operatorname{diam} G \le \zeta} \tfrac{\nu^*(G \cap \partial^* E)}{(\operatorname{diam} G)^{r-1}} > 0\}$$

is ν-negligible (471Pc), A is thin. By 484E(d-ii), there is a set $\mathcal{D}_0 \subseteq \mathcal{D}$ such that

$$A \subseteq \bigcup\{\operatorname{int}(\bigcup \mathcal{D}_1) : \mathcal{D}_1 \in [\mathcal{D}_0]^{<\omega}\}, \quad \bigcup \mathcal{D}_1 \in \mathcal{R}'' \text{ for every } \mathcal{D}_1 \in [\mathcal{D}_0]^\omega.$$

(ii) Write T' for the set of those δ-fine $\boldsymbol{t} \in T_\alpha$ such that every member of $\boldsymbol{t}$ is of the form $(x, D \cap E)$ for some $D \in \mathcal{D}$. If $x \in \operatorname{int}^* E \setminus A$, there is an $h(x) > 0$ such that $h(x) \le \theta(x)$ and $\{(x, D \cap E)\} \in T'$ whenever $D \in \mathcal{D}$, $x \in \overline{D}$ and $\operatorname{diam} D \le h(x)$. **P** Let $\epsilon_1 > 0$ be such that $\beta_r r^{r/2} \epsilon_1 \le \frac{1}{2}$ and

$$\alpha \le \tfrac{1 - r^{r/2}\epsilon_1}{r^{r/2}}, \quad \frac{1}{\alpha} \ge (2r + r^{r/2}\epsilon_1) \cdot \frac{1}{2^{r-1}} \big(\tfrac{\beta_r}{1 - r^{r/2}\epsilon_1}\big)^{(r-1)/r};$$

this is where we need to know that $\alpha < \alpha^*$. Because $x \notin A$, $\theta(x) > 0$; let $h(x) \le \theta(x)$ be such that (α) $\nu^*(D \cap \partial^* E) \le \epsilon_1 (\operatorname{diam} D)^{r-1}$ whenever $D \in \mathcal{D}$ and $x \in \overline{D}$ and $\operatorname{diam} D \le h(x)$ (β) $\mu(B(x,t) \setminus E) \le \epsilon_1 \mu B(x,t)$ whenever $0 \le t \le h(x)$. Now suppose that $D \in \mathcal{D}$ and $x \in \overline{D}$ and $\operatorname{diam} D \le h(x)$. Then, writing γ for the side length of D,

$$\begin{aligned}
\mu(D \cap E) &\ge \mu D - \mu(B(x, \operatorname{diam} D) \setminus E) \ge \gamma^r - \epsilon_1 \beta_r (\operatorname{diam} D)^r \\
&= \gamma^r (1 - r^{r/2}\epsilon_1) \ge \alpha \gamma^r r^{r/2} \\
&= \alpha (\operatorname{diam} D)^r \ge \alpha \operatorname{diam}(D \cap E)^r.
\end{aligned}$$

Since also $\mu(D \cap E) \le \frac{1}{2^r} \beta_r \operatorname{diam}(D \cap E)^r$ (264H), we see that

$$\operatorname{diam}(D \cap E) \ge 2\gamma \big(\tfrac{1 - r^{r/2}\epsilon_1}{\beta_r}\big)^{1/r}.$$

Next,

$$\operatorname{per}(D \cap E) = \nu(\partial^*(D \cap E)) \le \nu(\partial D) + \nu(D \cap \partial^* E)$$

(475Cf)

$$\begin{aligned}
&\le 2r\gamma^{r-1} + \epsilon_1 (\operatorname{diam} D)^{r-1} = \gamma^{r-1}(2r + r^{r/2}\epsilon_1) \\
&\le (2r + r^{r/2}\epsilon_1) \cdot \frac{1}{2^{r-1}} \big(\tfrac{\beta_r}{1 - \epsilon_r r^{r/2}}\big)^{(r-1)/r} \operatorname{diam}(D \cap E)^{r-1} \\
&\le \frac{1}{\alpha} \operatorname{diam}(D \cap E)^{r-1}.
\end{aligned}$$

So $D \cap E \in \mathcal{C}_\alpha$. Also, for every $s > 0$, there is a $D' \in \mathcal{D}$ such that $D' \subseteq D$ and $x \in \overline{D'}$ and $\operatorname{diam} D' \leq s$. In this case

$$\mu(B(x, \operatorname{diam} D') \setminus E) \leq \epsilon_1 \mu B(x, \operatorname{diam} D') = \epsilon_1 \beta_r (\operatorname{diam} D')^r = \epsilon_1 \beta_r r^{r/2} \mu D' \leq \tfrac{1}{2} \mu D',$$

so

$$\begin{aligned} \mu(D \cap E \cap B(x, \operatorname{diam} D')) &\geq \mu D' - \mu(B(x, \operatorname{diam} D') \setminus E) \\ &\geq \tfrac{1}{2} \mu D' = \frac{1}{2\beta_r r^{r/2}} \mu B(x, \operatorname{diam} D'). \end{aligned}$$

As $\operatorname{diam} D'$ is arbitrarily small, $x \in \operatorname{cl}^*(D \cap E)$ and $\boldsymbol{t} = \{(x, D \cap E)\} \in T_\alpha$. Finally, since $\operatorname{diam} D \leq \theta(x)$, $(x, D \cap E) \in \delta$ and $\boldsymbol{t} \in T'$. **Q**

(iii) Let $\mathcal{H}$ be the set of those $H \subseteq \mathbb{R}$ such that $W_{\boldsymbol{t}} \subseteq E \cap H \subseteq W_{\boldsymbol{t}} \cup \bigcup \mathcal{D}_1$ for some δ-fine $\boldsymbol{t} \in T'$ and finite $\mathcal{D}_1 \subseteq \mathcal{D}_0$. Then $H \cup H' \in \mathcal{H}$ whenever H, $H' \in \mathcal{H}$ are disjoint. If $\langle D_n \rangle_{n \in \mathbb{N}}$ is any strictly decreasing sequence in $\mathcal{D}$, then some D_n belongs to $\mathcal{H}$. **P** Let x be the unique point of $\bigcap_{n \in \mathbb{N}} \overline{D_n}$.

case 1 If $x \in A$, then there is a finite subset $\mathcal{D}_1$ of $\mathcal{D}_0$ whose union is a neighbourhood of x, and therefore includes D_n for some n; so $\boldsymbol{t} = \emptyset$ and $\mathcal{D}_1$ witness that $D_n \in \mathcal{H}$.

case 2 If $x \in E \setminus A$, then $x \in \operatorname{int}^* E$, so $h(x) > 0$ and there is some $n \in \mathbb{N}$ such that $\operatorname{diam} D_n \leq h(x)$. In this case $\boldsymbol{t} = \{(x, D_n \cap E)\}$ belongs to T', by the choice of $h(x)$, so that $\boldsymbol{t}$ and $\emptyset$ witness that $D_n \in \mathcal{H}$.

case 3 Finally, if $x \notin E \cup A$, then $x \notin \operatorname{cl}^* E$ so $x \notin \overline{E}$ and there is some n such that $D_n \cap E = \emptyset$, in which case $\boldsymbol{t} = \mathcal{D}_1 = \emptyset$ witness that $D_n \in \mathcal{H}$. **Q**

(iv) In fact $\mathbb{R}^r \in \mathcal{H}$. **P?** Otherwise, because $E \subseteq C$ is bounded, it can be covered by a finite disjoint family in $\mathcal{D}$, and there must be some $D_0 \in \mathcal{D} \setminus \mathcal{H}$. Now we can find $\langle D_n \rangle_{n \geq 1}$ in $\mathcal{D} \setminus \mathcal{H}$ such that $D_n \subseteq D_{n-1}$ and $\operatorname{diam} D_n = \frac{1}{2} \operatorname{diam} D_{n-1}$ for every n. But this contradicts (iii). **XQ**

(v) We therefore have a δ-fine $\boldsymbol{t} \in T'$ and a finite set $\mathcal{D}_1 \subseteq \mathcal{D}_0$ such that $W_{\boldsymbol{t}} \subseteq E \subseteq W_{\boldsymbol{t}} \cup \bigcup \mathcal{D}_1$. Now we can find $\boldsymbol{t}' \subseteq \boldsymbol{t}$ and $\mathcal{D}_1' \subseteq \mathcal{D}_1$ such that $W_{\boldsymbol{t}'} \cap \bigcup \mathcal{D}_1' = \emptyset$ and $W_{\boldsymbol{t}'} \cup \bigcup \mathcal{D}_1' = W_{\boldsymbol{t}'} \cup \bigcup \mathcal{D}_1$.

By the choice of $\mathcal{D}_0$, $\bigcup \mathcal{D}_1 \in \mathcal{R}''$; by the choice of $\mathcal{R}''$, $E \setminus W_{\boldsymbol{t}} = E \cap \bigcup \mathcal{D}_1$ belongs to $\mathcal{R}'$. But we know also that $C \cap V \setminus E \in \mathcal{R}'$, that is, $C \setminus E \in \mathcal{R}'$, because $\mathcal{R}' = \mathcal{R}_\eta^{(V)}$. By the choice of $\mathcal{R}'$, $C \setminus W_{\boldsymbol{t}} \in \mathcal{R}$. And $\boldsymbol{t} \in T'$ is a δ-fine member of T_α. As C, δ and $\mathcal{R}$ are arbitrary, 481G(vii) is satisfied, and the proof is complete.

484G The Pfeffer integral (a) For $\alpha \in]0, \alpha^*[$, write I_α for the linear functional defined by setting

$$I_\alpha(f) = \lim_{\boldsymbol{t} \to \mathcal{F}(T_\alpha, \Delta, \Re)} S_{\boldsymbol{t}}(f, \mu)$$

whenever $f : \mathbb{R}^r \to \mathbb{R}$ is such that the limit is defined. Then if $0 < \beta \leq \alpha$ and $I_\beta(f)$ is defined, so is $I_\alpha(f)$, and the two are equal. **P** All we have to observe is that $\mathcal{C}_\alpha \subseteq \mathcal{C}_\beta$ so that $T_\alpha \subseteq T_\beta$, while $\mathcal{F}(T_\alpha, \Delta, \Re)$ is just $\{A \cap T_\alpha : A \in \mathcal{F}(T_\beta, \Delta, \Re)\}$. **Q**

(b) Let $f : \mathbb{R}^r \to \mathbb{R}$ be a function. I will say that it is **Pfeffer integrable**, with **Pfeffer integral** $\text{⨍}_{\text{f}} f$, if

$$\text{⨍}_{\text{f}} f = \lim_{\alpha \downarrow 0} I_\alpha(f)$$

is defined; that is to say, if $I_\alpha(f)$ is defined whenever $0 < \alpha < \alpha^*$.

484H The first step is to work through the results of §482 to see which ideas apply directly to the limit integral ⨍_{f}.

Proposition (a) The domain of ⨍_{f} is a linear space of functions, and ⨍_{f} is a positive linear functional.

(b) If f, $g : \mathbb{R}^r \to \mathbb{R}$ are such that $|f| \leq g$ and $\text{⨍}_{\text{f}} g = 0$, then $\text{⨍}_{\text{f}} f$ is defined and equal to 0.

(c) If $f : \mathbb{R}^r \to \mathbb{R}$ is Pfeffer integrable, then there is a unique additive functional $F : \mathcal{C} \to \mathbb{R}$ such that whenever $\epsilon > 0$ and $0 < \alpha < \alpha^*$ there are $\delta \in \Delta$ and $\mathcal{R} \in \Re$ such that

$$\textstyle\sum_{(x,C) \in \boldsymbol{t}} |F(C) - f(x)\mu C| \leq \epsilon \text{ for every } \delta\text{-fine } \boldsymbol{t} \in T_\alpha,$$

$$|F(E)| \leq \epsilon \text{ whenever } E \in \mathcal{R}.$$

Moreover, $F(\mathbb{R}^r) = \text{Pff}\, f$.

(d) Every Pfeffer integrable function is Lebesgue measurable.

(e) Every Lebesgue integrable function is Pfeffer integrable, with the same integral.

(f) A non-negative function is Pfeffer integrable iff it is Lebesgue integrable.

proof (a)-(b) Immediate from 481C.

(c) For each $\alpha \in]0, \alpha^*[$ let F_α be the Saks-Henstock indefinite integral corresponding to the the structure $(\mathbb{R}^r, T_\alpha, \Delta, \mathfrak{R}, \mu)$. Then all the F_α coincide. **P** Suppose that $0 < \beta \leq \alpha < \alpha^*$. Then, for any $\epsilon > 0$, there are $\delta \in \Delta$, $\mathcal{R} \in \mathfrak{R}$ such that

$$\textstyle\sum_{(x,C)\in \boldsymbol{t}} |F_\beta(C) - f(x)\mu C| \leq \epsilon \text{ for every } \delta\text{-fine } \boldsymbol{t} \in T_\beta,$$

$$|F_\beta(E)| \leq \epsilon \text{ whenever } E \in \mathcal{R}.$$

Since $T_\alpha \subseteq T_\beta$, this means that

$$\textstyle\sum_{(x,C)\in \boldsymbol{t}} |F_\beta(C) - f(x)\mu C| \leq \epsilon \text{ for every } \delta\text{-fine } \boldsymbol{t} \in T_\alpha.$$

And this works for any $\epsilon > 0$. By the uniqueness assertion in 482B, F_β must be exactly the same as F_α. **Q**

So we have a single functional F; and 482B also tells us that

$$F(\mathbb{R}^r) = I_\alpha(f) = \text{Pff}\, f$$

for every α.

(d) In fact if there is any α such that $I_\alpha(f)$ is defined, f must be Lebesgue measurable. **P** We have only to check that the conditions of 482E are satisfied by μ, $\mathcal{C}$, T_α, Δ and $\mathfrak{R}$. The only items not covered by the checks above are (ii) and (v) of the list there. 482E(ii) is true because $C \setminus \text{cl}^*C$ is negligible for every $C \in \mathcal{C}$ (475C(f)). 482E(v) is true because if $\mu E < \infty$ and $\epsilon > 0$, there are $n \in \mathbb{N}$ and $\eta \in \text{H}$ such that $\mu(E \setminus B(\mathbf{0}, n) \leq \frac{1}{2}\epsilon$ and $\sum_{i=0}^{\infty} \eta(i) \leq \frac{1}{2}\epsilon$, so that

$$\mu(E \cap R) \leq \mu(E \setminus B(\mathbf{0}, n)) + \mu(R \cap B(\mathbf{0}, n)) \leq \epsilon$$

for every $R \in \mathcal{R}_\eta^{(B(\mathbf{0},n))}$. **Q**

(e) This time, we have to check that the conditions of 482F are satisfied by T_α, Δ and $\mathfrak{R}$ whenever $0 < \alpha < \alpha^*$. **P** Of course μ is inner regular with respect to the closed sets and outer regular with respect to the open sets (134F). Condition 482F(v) just repeats 482E(v), verified in (d) above. **Q**

(f) If $f \geq 0$ is integrable in the ordinary sense, then it is Pfeffer integrable, by (e). If it is Pfeffer integrable, then it is measurable; but also $\int g\, d\mu = \text{Pff}\, g \leq \text{Pff}\, f$ for every simple function $g \leq f$, so f is integrable (213B).

484I Definition If $f : \mathbb{R}^r \to \mathbb{R}$ is Pfeffer integrable, I will call the function $F : \mathcal{C} \to \mathbb{R}$ defined in 484Hc the **Saks-Henstock indefinite integral** of f.

484J In fact 484Hc characterizes the Pfeffer integral, just as the Saks-Henstock lemma can be used to define general gauge integrals based on tagged-partition structures allowing subdivisions.

Proposition Suppose that $f : \mathbb{R}^r \to \mathbb{R}$ and $F : \mathcal{C} \to \mathbb{R}$ are such that

(i) F is additive,

(ii) whenever $0 < \alpha < \alpha^*$ and $\epsilon > 0$ there is a $\delta \in \Delta$ such that $\sum_{(x,C)\in \boldsymbol{t}} |F(C) - f(x)\mu C| \leq \epsilon$ for every δ-fine $\boldsymbol{t} \in T_\alpha$,

(iii) for every $\epsilon > 0$ there is an $\mathcal{R} \in \mathfrak{R}$ such that $|F(E)| \leq \epsilon$ for every $E \in \mathcal{C} \cap \mathcal{R}$.

Then f is Pfeffer integrable and F is the Saks-Henstock indefinite integral of f.

proof By 482D, the gauge integral $I_\alpha(f)$ is defined and equal to $F(\mathbb{R}^r)$ for every $\alpha \in]0, \alpha^*[$. So f is Pfeffer integrable. Now 484Hc tells us that F must be its Saks-Henstock indefinite integral.

484K Lemma Suppose that $\alpha > 0$ and $0 < \alpha' < \alpha \min(\frac{1}{2}, 2^{r-1}(\frac{\alpha}{2\beta_r})^{(r-1)/r})$. If $E \in \mathcal{C}$ is such that $E \subseteq \text{cl}^*E$, then there is a $\delta \in \Delta$ such that $\{(x, C \cap E)\} \in T_{\alpha'}$ whenever $(x, C) \in \delta$, $x \in E$ and $\{(x, C)\} \in T_\alpha$.

proof Take $\epsilon > 0$ such that $\beta_r\epsilon \leq \frac{1}{2}\alpha$ and

$$\frac{1}{\alpha} + 2^{r-1}\epsilon \leq \frac{2^{r-1}}{\alpha'}\big(\frac{\alpha}{2\beta_r}\big)^{(r-1)/r}.$$

Set

$$A = \partial^*E \cup \{x : \lim_{\zeta\downarrow 0} \sup_{x\in G, 0<\operatorname{diam} G\leq\zeta} \frac{\nu^*(G\cap\partial^*E)}{(\operatorname{diam} G)^{r-1}} > 0\},$$

so that A is a thin set, as in the proof of 484F. (Of course ∂^*E is thin because $\nu(\partial^*E \cap B(\mathbf{0}, n))$ is finite for every $n \in \mathbb{N}$.)

For $x \in E \setminus A$, we have $x \in \operatorname{int}^*E$ (because $E \subseteq \operatorname{cl}^*E$), so there is a $\theta(x) > 0$ such that

$$\mu(B(x,\gamma) \setminus E) \leq \epsilon\mu B(x,\gamma), \quad \nu(\partial^*E \cap B(x,\gamma)) \leq \epsilon(2\gamma)^{r-1}$$

whenever $0 < \gamma \leq 2\theta(x)$. If we set $\theta(x) = 0$ for $x \in E \cap A$ and $\theta(x) = 1$ for $x \in \mathbb{R}^r \setminus E$, then $\theta \in \Theta$ and $\delta_\theta \in \Delta$.

Now suppose that $x \in E$, $(x, C) \in \delta_\theta$ and $\{(x, C)\} \in T_\alpha$, that is, that $C \in \mathcal{C}_\alpha$ and $x \in (E \cap \operatorname{cl}^*C) \setminus A$ and $C \subseteq B(x, \theta(x))$. Set $\gamma = \operatorname{diam} C \leq 2\theta(x)$. Then

$$\mu(C \setminus E) \leq \mu(B(x,\gamma) \setminus E) \leq \epsilon\mu B(x,\gamma) = \beta_r\epsilon\gamma^r,$$

so

$$\begin{aligned}\mu(C \cap E) &\geq \mu C - \beta_r\epsilon\gamma^r \geq (\alpha - \beta_r\epsilon)\gamma^r \\ &\geq \tfrac{1}{2}\alpha\gamma^r \geq \alpha'\gamma^r \geq \alpha' \operatorname{diam}(C \cap E)^r.\end{aligned}$$

Next,

$$\begin{aligned}\operatorname{per}(C \cap E) &= \nu(\partial^*(C \cap E)) \leq \nu(\partial^*C) + \nu(\operatorname{cl}^*C \cap \partial^*E) \\ &\leq \operatorname{per} C + \nu(B(x,\gamma) \cap \partial^*E) \leq \frac{1}{\alpha}\gamma^{r-1} + \epsilon(2\gamma)^{r-1} = (\tfrac{1}{\alpha} + 2^{r-1}\epsilon)\gamma^{r-1}.\end{aligned}$$

Moreover,

$$2^{-r}\beta_r \operatorname{diam}(C \cap E)^r \geq \mu(C \cap E) \geq \tfrac{1}{2}\alpha\gamma^r$$

(264H), so $\operatorname{diam}(C \cap E) \geq 2(\frac{\alpha}{2\beta_r})^{1/r}\gamma$ and

$$\operatorname{per}(C \cap E) \leq (\tfrac{1}{\alpha} + 2^{r-1}\epsilon) \cdot \frac{1}{2^{r-1}}\big(\frac{2\beta_r}{\alpha}\big)^{(r-1)/r} \operatorname{diam}(C \cap E)^{r-1} \leq \frac{1}{\alpha'} \operatorname{diam}(C \cap E)^{r-1}.$$

Putting these together, we see that $C \in \mathcal{C}_{\alpha'}$.

Finally, because $x \in \operatorname{cl}^*C \cap \operatorname{int}^*E \subseteq \operatorname{cl}^*(C \cap E)$, $\{(x, C \cap E)\} \in T_{\alpha'}$.

484L Proposition Suppose that $f : \mathbb{R}^r \to \mathbb{R}$ is Pfeffer integrable, and that $F : \mathcal{C} \to \mathbb{R}$ is its Saks-Henstock indefinite integral. Then $\int f \times \chi E$ is defined and equal to $F(E)$ for every $E \in \mathcal{C}$.

proof (a) To begin with (down to the end of (d) below), suppose that $E \in \mathcal{C}$ is such that $\operatorname{int}^*E \subseteq E \subseteq \operatorname{cl}^*E$. For $G \in \mathcal{C}$ set $F_1(G) = F(G \cap E)$. I seek to show that F_1 satisfies the conditions of 484J.

Of course $F_1 : \mathcal{C} \to \mathbb{R}$ is additive. If $\epsilon > 0$, there is an $\mathcal{R} \in \mathfrak{R}$ such that $|F(G)| \leq \epsilon$ whenever $G \in \mathcal{R}$, by 484H; now there is an $\mathcal{R}' \in \mathfrak{R}$ such that $G \cap E \in \mathcal{R}$ for every $G \in \mathcal{R}'$ (484E(a-ii)), so that $|F_1(G)| \leq \epsilon$ for every $G \in \mathcal{C} \cap \mathcal{R}'$. Thus F_1 satisfies (iii) of 484J.

(b) Take $\alpha \in]0, \alpha^*[$ and $\epsilon > 0$. Take α' such that $0 < \alpha' < \alpha \min(\frac{1}{2}, 2^{r-1}(\frac{\alpha}{2\beta_r})^{(r-1)/r})$. Applying 484K to E and its complement, and appealing to the definition of F, we see that there is a $\delta \in \Delta$ such that

(α) $\{(x, C \cap E)\} \in T_{\alpha'}$ whenever $(x, C) \in \delta$, $x \in E$ and $\{(x, C)\} \in T_\alpha$,

(β) $\{(x, C \setminus E)\} \in T_{\alpha'}$ whenever $(x, C) \in \delta$, $x \in \mathbb{R}^r \setminus E$ and $\{(x, C)\} \in T_\alpha$,

(γ) $\sum_{(x,C)\in\boldsymbol{t}} |F(C) - f(x)\mu C| \leq \epsilon$ for every δ-fine $\boldsymbol{t} \in T_{\alpha'}$.

(For (α), we need to know that $E \subseteq \text{cl}^*E$ and for (β) we need $\text{int}^*E \subseteq E$.) Next, choose for each $n \in \mathbb{N}$ closed sets $H_n \subseteq E$, $H_n' \subseteq \mathbb{R}^r \setminus E$ such that $\mu(E \setminus H_n) \leq 2^{-n}\epsilon$ and $\mu((\mathbb{R}^r \setminus E) \setminus H_n') \leq 2^{-n}\epsilon$. Define $\theta : \mathbb{R}^r \to]0, \infty[$ by setting

$$\theta(x) = \min(1, \tfrac{1}{2}\rho(x, H_n')) \text{ if } x \in E \text{ and } n \leq |f(x)| < n+1,$$

$$= \min(1, \tfrac{1}{2}\rho(x, H_n)) \text{ if } x \in \mathbb{R}^r \setminus E \text{ and } n \leq |f(x)| < n+1,$$

writing $\rho(x, A) = \inf_{y \in A} \|x - y\|$ if $A \subseteq \mathbb{R}^r$ is non-empty, ∞ if $A = \emptyset$. Then $\delta_\theta \in \Delta$. Let $\mathcal{R}_1 \in \mathfrak{R}$ be such that $A \cap E \in \mathcal{R}$ whenever $A \in \mathcal{R}_1$ (484E(a-ii)).

(c) Write f_E for $f \times \chi E$. Then $\sum_{(x,C) \in \boldsymbol{t}} |F_1(C) - f_E(x)\mu(C)| \leq 11\epsilon$ whenever $\boldsymbol{t} \in T_\alpha$ is $\delta \cap \delta_\theta$-fine. **P** Set

$$\boldsymbol{t}' = \{(x, C \cap E) : (x, C) \in \boldsymbol{t},\, x \in E\}.$$

By clause (α) of the choice of δ, $\boldsymbol{t}' \in T_{\alpha'}$, and of course it is δ-fine. So

$$\textstyle\sum_{(x,C) \in \boldsymbol{t}, x \in E} |F(C \cap E) - f(x)\mu(C \cap E)| \leq \epsilon$$

by clause (γ) of the choice of δ. Next,

$$\sum_{(x,C) \in \boldsymbol{t}, x \in E} |f(x)\mu(C \setminus E)| = \sum_{n=0}^{\infty} \sum_{\substack{(x,C) \in \boldsymbol{t}, x \in E \\ n \leq |f(x)| < n+1}} |f(x)|\mu(C \setminus E)$$

$$\leq \sum_{n=0}^{\infty} (n+1)\mu((\mathbb{R}^r \setminus E) \setminus H_n')$$

(because $\text{diam}\, C \leq \theta(x)$, so $C \cap H_n' = \emptyset$ whenever $(x, C) \in \boldsymbol{t}$, $x \in E$ and $n \leq |f(x)| < n+1$)

$$\leq \sum_{n=0}^{\infty} 2^{-n}(n+1)\epsilon = 4\epsilon,$$

and

$$\textstyle\sum_{(x,C) \in \boldsymbol{t}, x \in E} |F(C \cap E) - f(x)\mu C| \leq 5\epsilon.$$

Similarly,

$$\textstyle\sum_{(x,C) \in \boldsymbol{t}, x \notin E} |F(C \setminus E) - f(x)\mu C)| \leq 5\epsilon.$$

But as

$$\textstyle\sum_{(x,C) \in \boldsymbol{t}, x \notin E} |F(C) - f(x)\mu C| \leq \epsilon$$

(because surely $\boldsymbol{t}$ itself belongs to $T_{\alpha'}$), we have

$$\textstyle\sum_{(x,C) \in \boldsymbol{t}, x \notin E} |F(C \cap E)| \leq 6\epsilon.$$

Putting these together,

$$\sum_{(x,C) \in \boldsymbol{t}} |F_1(C) - f_E(x)\mu C| = \sum_{\substack{(x,C) \in \boldsymbol{t} \\ x \in E}} |F(C \cap E) - f(x)\mu C| + \sum_{\substack{(x,C) \in \boldsymbol{t} \\ x \notin E}} |F(C \cap E)|$$

$$\leq 5\epsilon + 6\epsilon = 11\epsilon. \textbf{ Q}$$

(d) As α and ϵ are arbitrary, condition (iii) of 484J is satisfied by F_1 and f_E, so $\int_{\text{ff}} f_E = F_1(\mathbb{R}^r) = F(E)$.

(e) This completes the proof when $\text{int}^*E \subseteq E \subseteq \text{cl}^*E$. For a general set $E \in \mathcal{C}$, set $E_1 = (E \cup \text{int}^*E) \cap \text{cl}^*E$. Then $E \triangle E_1$ is negligible, so

$$\text{int}^*E_1 = \text{int}^*E \subseteq E_1 \subseteq \text{cl}^*E = \text{cl}^*E_1.$$

Also $\int\!\!\!\!\!\!\int f \times \chi(E \setminus E_1) = \int f \times \chi(E \setminus E_1)d\mu$, $\int\!\!\!\!\!\!\int f \times \chi(E_1 \setminus E) = \int f \times \chi(E \setminus E_1)d\mu$ are both zero, and

$$\int\!\!\!\!\!\!\int f \times \chi E = \int\!\!\!\!\!\!\int f \times \chi E_1 = F(E_1) = F(E).$$

(To see that $F(E_1) = F(E)$, note that $E \setminus E_1$ and $E_1 \setminus E$, being negligible sets, have empty essential boundary and zero perimeter, so belong to every member of $\mathfrak{R}$, by 484E(b-ii), or otherwise.)

484M Lemma Let G, $H \in \mathcal{C}$ be disjoint and $\phi : \mathbb{R}^r \to \mathbb{R}^r$ a continuous function. If *either* $G \cup H$ is bounded *or* ϕ has compact support,

$$\int_{\partial^*(G\cup H)} \phi.\psi_{G\cup H}\, d\nu = \int_{\partial^* G} \phi.\psi_G\, d\nu + \int_{\partial^* H} \phi.\psi_G\, d\nu,$$

where ψ_G, ψ_H and $\psi_{G\cup H}$ are the canonical outward-normal functions (474G).

proof (a) Suppose first that ϕ is a Lipschitz function with compact support. Then 475N tells us that

$$\begin{aligned}\int_{\partial^*(G\cup H)} \phi.\psi_{G\cup H}\, d\nu &= \int_{G\cup H} \operatorname{div}\phi\, d\mu = \int_G \operatorname{div}\phi\, d\mu + \int_H \operatorname{div}\phi\, d\mu \\ &= \int_{\partial^* G} \phi.\psi_G\, d\nu + \int_{\partial^* H} \phi.\psi_G\, d\nu.\end{aligned}$$

(Recall from 474Q that we can identify outward-normal functions with Federer exterior normals, as in the statment of 475N.)

(b) Now suppose that ϕ is a continuous function with compact support. Let $\langle \tilde{h}_n\rangle_{n\in\mathbb{N}}$ be the smoothing sequence of 473E. Then all the functions $\phi * \tilde{h}_n$ are Lipschitz (473Ca), and $\langle \phi * \tilde{h}_n\rangle_{n\in\mathbb{N}}$ converges uniformly to ϕ (473Df, 473Ed). So

$$\begin{aligned}\int_{\partial^*(G\cup H)} \phi.\psi_{G\cup H}\, d\nu &= \lim_{n\to\infty} \int_{\partial^*(G\cup H)} (\phi * \tilde{h}_n).\psi_{G\cup H}\, d\nu \\ &= \lim_{n\to\infty} \int_{\partial^* G} (\phi * \tilde{h}_n).\psi_G\, d\nu + \lim_{n\to\infty} \int_{\partial^* H} (\phi * \tilde{h}_n).\psi_H\, d\nu \\ &= \int_{\partial^* G} \phi.\psi_G\, d\nu + \int_{\partial^* H} \phi.\psi_G\, d\nu.\end{aligned}$$

(c) If, on the other hand, ϕ is continuous and G and H are bounded, then we can find a continuous function $\tilde{\phi}$ with compact support agreeing with ϕ on $\overline{G \cup H}$ (4A2G(e-i), or otherwise); applying (b) to $\tilde{\phi}$, we get the required result for ϕ.

484N Pfeffer's Divergence Theorem Let $E \subseteq \mathbb{R}^r$ be a set with locally finite perimeter, and $\phi : \mathbb{R}^r \to \mathbb{R}^r$ a continuous function with compact support such that $\{x : x \in \mathbb{R}^r, \phi \text{ is not differentiable at } x\}$ is thin. Let v_x be the Federer exterior normal to E at any point x where the normal exists. Then $\int\!\!\!\!\!\!\int \operatorname{div}\phi \times \chi E$ is defined and equal to $\int_{\partial^* E} \phi(x).v_x\nu(dx)$.

proof (a) Let n be such that $\phi(x) = \mathbf{0}$ for $\|x\| \geq n$. For $C \in \mathcal{C}$, set $F(C) = \int_{\partial^* C} \phi.\psi_C\nu(dx)$. By 484M, F is additive.

(b) If $0 < \alpha < \alpha^*$ and $\epsilon > 0$ and $x \in \mathbb{R}^r$ is such that ϕ is differentiable at x, there is a $\gamma > 0$ such that $|F(C) - \operatorname{div}\phi(x)\mu C| \leq \epsilon\mu C$ whenever $C \in \mathcal{C}_\alpha$, $x \in \overline{C}$ and $\operatorname{diam} C \leq \gamma$. **P** Let T be the derivative of ϕ at x. Let $\gamma > 0$ be such that $\|\phi(y) - \phi(x) - T(y-x)\| \leq \alpha^2\epsilon\|y - x\|$ whenever $\|y - x\| \leq \gamma$. Let $\tilde{\phi} : \mathbb{R}^r \to \mathbb{R}^r$ be a Lipschitz function with compact support such that $\tilde{\phi}(y) = \phi(x) + (y - x)$ whenever $\|y - x\| \leq \gamma$ (473Cf). If $C \in \mathcal{C}_\alpha$ has diameter at most γ and $x \in \overline{C}$, then

$$|F(C) - \operatorname{div}\phi(x)\mu C| = |\int_{\partial^* C} \phi.\psi_C\nu(dx) - \int_C \operatorname{div}\tilde{\phi}\, d\mu|$$

(because T is the derivative of $\tilde{\phi}$ everywhere on $B(x,\gamma)$, so $\operatorname{div}\tilde{\phi}(y) = \operatorname{div}\phi(x)$ for every $y \in C$)

$$= |\int_{\partial^* C} \phi - \tilde{\phi}.\psi_C \nu(dx)|$$

(applying the Divergence Theorem to $\tilde{\phi}$)

$$\leq \nu(\partial^* C) \sup_{y \in C} \|\phi(y) - \tilde{\phi}(y)\| \leq \alpha^2 \epsilon \operatorname{diam} C \operatorname{per} C$$
$$\leq \alpha\epsilon(\operatorname{diam} C)^r \leq \epsilon\mu C$$

because $C \in \mathcal{C}_\alpha$. **Q**

(c) If $\epsilon > 0$ and $\alpha \in]0, \alpha^*[$, there is a $\delta \in \Delta$ such that $\sum_{(x,C)\in \boldsymbol{t}} |F(C) - \operatorname{div}\phi(x)\mu C| \leq \epsilon$ whenever $\boldsymbol{t} \in T_\alpha$ is δ-fine. **P** Let $\zeta > 0$ be such that $\zeta\mu B(\mathbf{0}, n+2) \leq \epsilon$. Set $A = \{x : x \in \mathbb{R}^r, \phi \text{ is not differentiable at } x\}$, and for $x \in \mathbb{R}^r \setminus A$, let $\theta(x) \in]0, \frac{1}{2}]$ be such that $|F(C) - \operatorname{div}\phi(x)\mu C| \leq \zeta\mu C$ whenever $C \in \mathcal{C}_\alpha$, $x \in \overline{C}$ and $\operatorname{diam} C \leq \theta(x)$; for $x \in A$ set $\theta(x) = 0$. Now suppose that $\boldsymbol{t} \in T_\alpha$ is δ_θ-fine. Then

$$\sum_{(x,C)\in\boldsymbol{t}} |F(C) - \operatorname{div}\phi(x)\mu C| = \sum_{(x,C)\in\boldsymbol{t}, x\in B(\mathbf{0},n+1)} |F(C) - \operatorname{div}\phi(x)\mu C|$$

(because $\operatorname{diam} C \leq 1$ whenever $(x, C) \in \boldsymbol{t}$, so if $\|x\| > n+1$ then $F(C) = \operatorname{div}\phi(x) = 0$)

$$\leq \sum_{(x,C)\in\boldsymbol{t}, x\in B(\mathbf{0},n+1)} \zeta\mu C \leq \zeta\mu B(\mathbf{0}, n+2) \leq \epsilon. \ \mathbf{Q}$$

(d) Because ϕ is a continuous function with compact support, it is uniformly continuous (apply 4A2Je to each of the coordinates of ϕ). For $\zeta > 0$, let $\gamma(\zeta) > 0$ be such that $\|\phi(x) - \phi(y)\| \leq \zeta$ whenever $\|x - y\| \leq \gamma(\zeta)$.

If $C \in \mathcal{C}$ and $\operatorname{per} C \leq 1$ and $\mu C \leq \zeta\gamma(\zeta)$, where $\zeta > 0$, then $|F(C)| \leq r\zeta(2\|\phi\|_\infty + \frac{1}{2})$, writing $\|\phi\|_\infty$ for $\sup_{x\in\mathbb{R}^r} \|\phi(x)\|$. **P** For $1 \leq i \leq r$, let $\phi_i : \mathbb{R}^r \to \mathbb{R}$ be the ith component of ϕ, and v_i the ith unit vector $(0, \dots, 1, \dots, 0)$; write

$$\beta_i = \textstyle\int_{\partial^* C} \phi_i(x)(v_i | \psi_E(x))\nu(dx),$$

so that $F(C) = \sum_{i=1}^r \beta_i$. I start by examining β_r. By 475O, we have sequences $\langle H_n\rangle_{n\in\mathbb{N}}$, $\langle g_n\rangle_{n\in\mathbb{N}}$ and $\langle g'_n\rangle_{n\in\mathbb{N}}$ such that

(i) for each $n \in \mathbb{N}$, H_n is a Lebesgue measurable subset of $\mathbb{R}^{r-1}$, and g_n, $g'_n : H_n \to [-\infty, \infty]$ are Lebesgue measurable functions such that $g_n(u) < g'_n(u)$ for every $u \in F_n$;

(ii) if m, $n \in \mathbb{N}$ then $g_m(u) \neq g'_n(u)$ for every $u \in H_m \cap H_n$;

(iii) $\sum_{n=0}^\infty \int_{H_n} g'_n - g_n d\mu_{r-1} = \mu C$;

(iv)

$$\beta_r = \textstyle\sum_{n=0}^\infty \int_{H_n} \phi_r(u, g'_n(u)) - \phi_r(u, g_n(u))\mu_{r-1}(du),$$

where we interpret $\phi_r(u, \infty)$ and $\phi_r(u, -\infty)$ as 0 if necessary;

(v) for μ_{r-1}-almost every $u \in \mathbb{R}^{r-1}$,

$$\{t : (u,t) \in \partial^* C\} = \{g_n(u) : n \in \mathbb{N}, u \in F_n, g_n(u) \neq -\infty\} \cup \{g'_n(u) : n \in \mathbb{N}, u \in F_n, g'_n(u) \neq \infty\}.$$

From (iii) we see that g'_n and g_n are both finite almost everywhere on H_n, for every n. Consequently, by (v),

$$2\textstyle\sum_{n=0}^\infty \mu_{r-1}H_n = \int \#(\{t : (u,t) \in \partial^* C\})\mu_{r-1}(du) \leq \nu(\partial^* C) \leq 1$$

by 475H. For each n, set

$$H'_n = \{u : u \in H_n, g'_n(u) - g_n(u) > \gamma(\zeta)\}.$$

Then $\gamma(\zeta)\sum_{n=0}^\infty \mu H'_n \leq \mu C$ so $\sum_{n=0}^\infty \mu H'_n \leq \zeta$ and

$$|\sum_{n=0}^\infty \int_{H'_n} \phi_r(u, g'_n(u)) - \phi_r(u, g_n(u))\mu_{r-1}(du)| \leq 2\|\phi\|_\infty \sum_{n=0}^\infty \mu H'_n \leq 2\zeta\|\phi\|_\infty.$$

On the other hand, for $n \in \mathbb{N}$ and $u \in H_n \setminus H_n'$, $|\phi_r(u, g_n'(u)) - \phi_r(u, g_n(u))| \leq \zeta$, so

$$|\sum_{n=0}^{\infty} \int_{H_n \setminus H_n'} \phi_r(u, g_n'(u)) - \phi_r(u, g_n(u))\mu_{r-1}(du)| \leq \sum_{n=0}^{\infty} \zeta\mu(H_n \setminus H_n') \leq \tfrac{1}{2}\zeta.$$

Putting these together,

$$\beta_r \leq 2\zeta\|\phi\|_\infty + \tfrac{1}{2}\zeta.$$

But of course the same arguments apply to all the β_i, so

$$|F(C)| \leq \textstyle\sum_{i=1}^{r} |\beta_i| \leq r\zeta(2\|\phi\|_\infty + \frac{1}{2}),$$

as claimed. **Q**

(e) If $\epsilon > 0$ there is an $\mathcal{R} \in \mathfrak{R}$ such that $|F(C)| \leq \epsilon$ for every $C \in \mathcal{C} \cap \mathcal{R}$. **P** Let $\langle \epsilon_i \rangle_{i \in \mathbb{N}}$ be a sequence of strictly positive real numbers such that $r(2\|\phi\|_\infty + \frac{1}{2}) \sum_{i=0}^{\infty} \epsilon_i \leq \epsilon$. For each $i \in \mathbb{N}$, set $\eta(i) = \epsilon_i \gamma(\epsilon_i) > 0$. Set $V = B(\mathbf{0}, n+1)$, and take any $C \in \mathcal{C} \cap \mathcal{R}_\eta^{(V)}$. Then $F(C \setminus V) = 0$, so $F(C) = F(C \cap V)$, while $C \cap V \in \mathcal{R}_\eta$. Express $C \cap V$ as $\bigcup_{i \leq n} E_i$, where $\langle E_i \rangle_{i \leq n}$ is disjoint, $\operatorname{per} E_i \leq 1$ and $\mu E_i \leq \eta(i)$ for each i. Then $|F(E_i)| \leq r\epsilon_i(2\|\phi\|_\infty + \frac{1}{2})$ for each i, by (d), so

$$|F(C \cap V)| \leq \textstyle\sum_{i=0}^{n} |F(E_i)| \leq \epsilon,$$

as required. **Q**

(f) By 484J, $\operatorname{div} \phi$ is Pfeffer integrable. Moreover, by the uniqueness assertion in 484Hc, its Saks-Henstock indefinite integral is just the function F here. By 484L, $F(E) = \int \operatorname{div} \phi \times \chi E$, as required.

484O Differentiating the indefinite integral: Theorem Let $f : \mathbb{R}^r \to \mathbb{R}$ be a Pfeffer integrable function, and F its Saks-Henstock indefinite integral. Then whenever $0 < \alpha < \alpha^*$,

$$\begin{aligned} f(x) &= \lim_{\zeta \downarrow 0} \sup\{\frac{F(C)}{\mu C} : C \in \mathcal{C}_\alpha,\ x \in \overline{C},\ 0 < \operatorname{diam} C \leq \zeta\} \\ &= \lim_{\zeta \downarrow 0} \inf\{\frac{F(C)}{\mu C} : C \in \mathcal{C}_\alpha,\ x \in \overline{C},\ 0 < \operatorname{diam} C \leq \zeta\} \end{aligned}$$

for μ-almost every $x \in \mathbb{R}^r$.

proof (a) It will be useful to know the following: if $C \in \mathcal{C}_\alpha$, $\operatorname{diam} C > 0$, $x \in \overline{C}$ and $\epsilon > 0$, then for any sufficiently small $\zeta > 0$, $C \cup B(x, \zeta) \in C_{\alpha/2}$ and $|F(C \cup B(x, \zeta)) - F(C)| \leq \epsilon$. **P** Let $\mathcal{R} \in \mathfrak{R}$ be such that $|F(R)| \leq \epsilon$ whenever $R \in \mathcal{C} \cap \mathcal{R}$, let $\mathcal{R}' \in \mathfrak{R}$ be such that $(\mathbb{R}^r \setminus C) \cap R \in \mathcal{R}$ whenever $R' \in \mathcal{R}'$, and let $\eta \in \mathrm{H}$ be such that $\mathcal{R}_\eta \subseteq \mathcal{R}'$. Then for all sufficiently small $\zeta > 0$, we shall have $\operatorname{per} B(x, \zeta) \leq 1$ and $\mu B(x, \zeta) \leq \eta(0)$, so that $B(x, \zeta) \in \mathcal{R}_\eta$ and

$$|F(C \cup B(x, \zeta)) - F(C)| = |F(B(x, \zeta) \setminus C| \leq \epsilon.$$

Next, for all sufficiently small $\zeta > 0$,

$$\begin{aligned} \mu(C \cup B(x, \zeta)) &\geq \mu C \geq \alpha(\operatorname{diam} C)^r \\ &\geq \frac{\alpha}{2}(\zeta + \operatorname{diam} C)^r \geq \frac{\alpha}{2} \operatorname{diam}(C \cup B(x, \zeta))^r \end{aligned}$$

and

$$\begin{aligned} \operatorname{per}(C \cup B(x, \zeta)) &\leq \operatorname{per} C + \operatorname{per} B(x, \zeta) \leq \frac{1}{\alpha}(\operatorname{diam} C)^{r-1} + \operatorname{per} B(x, \zeta) \\ &\leq \frac{2}{\alpha}(\operatorname{diam} C)^{r-1} \leq \frac{2}{\alpha} \operatorname{diam}(C \cup B(x, \zeta))^{r-1}, \end{aligned}$$

so that $C \cup B(x, \zeta) \in \mathcal{C}_{\alpha/2}$. **Q**

(b) For $x \in \mathbb{R}$, set

$$g(x) = \lim_{\zeta \downarrow 0} \sup\{\frac{F(C)}{\mu C} : C \in \mathcal{C}_\alpha,\ x \in \overline{C},\ \operatorname{diam} C \leq \delta\}.$$

? Suppose, if possible, that there are rational numbers $q < q'$ and $n \in \mathbb{N}$ such that $A = \{x : \|x\| \leq n,\ f(x) \leq q < q' < g(x)\}$ is not μ-negligible. Set

$$\epsilon = \frac{(q-q')\alpha}{4 \cdot 5^r \beta_r} \mu^* A > 0.$$

Let $\theta \in \Theta$ be such that

$$\textstyle\sum_{(x,C) \in \boldsymbol{t}} |F(C) - f(x)\mu C| \leq \epsilon$$

for every δ_θ-fine $\boldsymbol{t} \in T_{\alpha/2}$. Let $\mathcal{I}$ be the family of all balls $B(x, \zeta)$ where $x \in A$, $0 < \zeta \leq \theta(x)$ and there is a $C \in \mathcal{C}_\alpha$ such that $x \in \overline{C}$, $\operatorname{diam} C = \zeta$ and $\frac{F(C)}{\mu C} > q'$. Then every member of $A_1 = A \setminus \theta^{-1}[\{0\}]$ is the centre of arbitrarily small members of $\mathcal{I}$, so by 472B there is a countable disjoint family $\mathcal{J}_0 \subseteq \mathcal{I}$ such that

$$\mu(\textstyle\bigcup \mathcal{J}_0) \geq 5^{-r} \mu^* A_1 = 5^{-r} \mu^* A.$$

There is therefore a finite family $\mathcal{J}_1 \subseteq \mathcal{J}_0$ such that $\mu(\bigcup \mathcal{J}_1) > \frac{1}{2 \cdot 5^r} \mu^* A$; enumerate $\mathcal{J}_1$ as $\langle B(x_i, \zeta_i) \rangle_{i \leq n}$ where, for each $i \leq n$, $x_i \in A$, $0 < \zeta_i \leq \theta_i(x)$ and there is a $C_i \in \mathcal{C}_\alpha$ such that $x_i \in \overline{C_i}$, $\operatorname{diam} C_i = \zeta_i$ and $F(C_i) > q' \mu C_i$. By (a), we can enlarge C_i by adding a sufficiently small ball around x_i to form a $C_i' \in \mathcal{C}_{\alpha/2}$ such that $x_i \in \operatorname{int} C_i'$, $C_i' \subseteq B(x_i, \zeta_i)$ and $F(C_i') \geq q' \mu C_i'$.

Consider $\boldsymbol{t} = \{(x_i, C_i') : i \leq n\}$. Then, because the balls $B(x_i, \zeta_i)$ are disjoint, and $x_i \in \operatorname{int} C_i' \subseteq \operatorname{cl}^* C_i'$ for every i, $\boldsymbol{t}$ is a δ_θ-fine member of $T_{\alpha/2}$. So $\sum_{i=0}^n F(C_i') \leq \epsilon + \sum_{i=0}^n f(x_i) \mu C_i'$. But as $F(C_i') \geq q' \mu C_i'$ and $f(x_i) \leq q$ for every i, this means that $(q' - q) \sum_{i=0}^n \mu C_i' \leq \epsilon$.

But now remember that $\operatorname{diam} C_i' \geq \operatorname{diam} C_i = \zeta_i$ and that $C_i' \in \mathcal{C}_{\alpha/2}$ for each i. This means that

$$\mu C_i' \geq \frac{\alpha}{2} \zeta_i^r \geq \frac{\alpha}{2\beta_r} \mu B(x_i, \zeta_i)$$

for each i, and

$$\begin{aligned}
\epsilon &\geq (q - q') \sum_{i=0}^n \mu C_i' \\
&\geq \frac{(q-q')\alpha}{2\beta_r} \sum_{i=0}^n \mu B(x_i, \zeta_i) \\
&> \frac{(q-q')\alpha}{4 \cdot 5^r \beta_r} \mu^* A = \epsilon
\end{aligned}$$

which is absurd. **X**

(c) Since q, q' and n are arbitrary, this means that $g \leq_{\text{a.e.}} f$. Similarly (or applying (b) to $-f$ and $-F$)

$$f(x) \leq \lim_{\zeta \downarrow 0} \inf\{\frac{F(C)}{\mu C} : C \in \mathcal{C}_\alpha,\ x \in \overline{C},\ 0 < \operatorname{diam} C \leq \zeta\}$$

for almost all x, as required.

484P Lemma Let $\phi : \mathbb{R}^r \to \mathbb{R}^r$ be an injective Lipschitz function, and H the set of points at which it is differentiable; for $x \in H$, write $T(x)$ for the derivative of ϕ at x and $J(x)$ for $|\det T(x)|$. Then, for μ-almost every $x \in \mathbb{R}^r$,

$$\begin{aligned}
J(x) &= \lim_{\zeta \downarrow 0} \sup\{\frac{\mu\phi[C]}{\mu C} : C \in \mathcal{C}_\alpha,\ x \in \overline{C},\ 0 < \operatorname{diam} C \leq \zeta\} \\
&= \lim_{\zeta \downarrow 0} \inf\{\frac{\mu\phi[C]}{\mu C} : C \in \mathcal{C}_\alpha,\ x \in \overline{C},\ 0 < \operatorname{diam} C \leq \zeta\}
\end{aligned}$$

for every $\alpha > 0$.

proof By Rademacher's theorem (262Q), H is conegligible. Let H' be the Lebesgue set of J, so that H' is also conegligible (261E). Take any $x \in H'$ and $\epsilon > 0$. Then there is a $\zeta_0 > 0$ such that $\int_{B(x,\zeta)} |J(y) - J(x)|\mu(dy) \leq \epsilon\mu B(x,\zeta)$ for every $\zeta \in [0,\zeta_0]$. Now suppose that $C \in \mathcal{C}_\alpha$, $x \in \overline{C}$ and $0 < \operatorname{diam} C \leq \zeta_0$. Then $\mu(C \setminus H) = 0$ so $\mu\phi[C \setminus H] = 0$ (262D), and

$$\mu\phi[C] = \mu\phi[C \cap H] = \int_{C\cap H} J\,d\mu$$

(263D(iv)). So

$$\begin{aligned}|\mu\phi[C] - J(x)\mu C| &= |\int_{C\setminus H} J\,d\mu - J(x)\mu(C\cap H)| \leq \int_{C\setminus H} |J(y)-J(x)|d\mu\\ &\leq \int_{B(x,\operatorname{diam} C)} |J(y)-J(x)|d\mu \leq \epsilon\mu B(x,\operatorname{diam} C)\\ &= \beta_r\epsilon(\operatorname{diam} C)^r \leq \frac{\beta_r\epsilon}{\alpha}\mu C.\end{aligned}$$

Thus $|\frac{\mu\phi[C]}{\mu C} - J(x)| \leq \frac{\beta_r}{\alpha}\epsilon$ whenever $C \in \mathcal{C}_\alpha$, $x \in \overline{C}$ and $0 < \operatorname{diam} C \leq \zeta_0$; as ϵ is arbitrary,

$$\begin{aligned}J(x) &= \lim_{\zeta\downarrow 0} \sup\{\tfrac{\mu\phi[C]}{\mu C} : C \in \mathcal{C}_\alpha,\ x \in \overline{C},\ 0 < \operatorname{diam} C \leq \zeta\}\\ &= \lim_{\zeta\downarrow 0} \inf\{\tfrac{\mu\phi[C]}{\mu C} : C \in \mathcal{C}_\alpha,\ x \in \overline{C},\ 0 < \operatorname{diam} C \leq \zeta\}.\end{aligned}$$

And this is true for μ-almost every x.

484Q Definition If (X,ρ) and (Y,σ) are metric spaces, a function $\phi : X \to Y$ is a **lipeomorphism** if it is bijective and both ϕ and ϕ^{-1} are Lipschitz. Of course a lipeomorphism is a homeomorphism.

484R Lemma Let $\phi : \mathbb{R}^r \to \mathbb{R}^r$ be a lipeomorphism.

(a) For any set $A \subseteq \mathbb{R}^r$,

$$\text{cl}^*(\phi[A]) = \phi[\text{cl}^*A], \quad \text{int}^*(\phi[A]) = \phi[\text{int}^*A], \quad \partial^*(\phi[A]) = \phi[\partial^*A].$$

(b) $\phi[C] \in \mathcal{C}$ for every $C \in \mathcal{C}$, and $\phi[V] \in \mathcal{V}$ for every $V \in \mathcal{V}$.

(c) For any $\alpha > 0$ there is an $\alpha' \in]0,\alpha]$ such that $\phi[C] \in \mathcal{C}_{\alpha'}$ for every $C \in \mathcal{C}_\alpha$ and $\{(\phi(x),\phi[C]) : (x,C) \in \boldsymbol{t}\}$ belongs to $T_{\alpha'}$ for every $\boldsymbol{t} \in T_\alpha$.

(d) For any $\mathcal{R} \in \mathfrak{R}$ there is an $\mathcal{R}' \in \mathfrak{R}$ such that $\phi[R] \in \mathcal{R}$ for every $R \in \mathcal{R}'$.

(e) $\theta\phi : \mathbb{R}^r \to [0,\infty[$ belongs to Θ for every $\theta \in \Theta$.

proof Let γ be so large that it is a Lipschitz constant for both ϕ and ϕ^{-1}. Observe that in this case

$$\phi^{-1}[B(\phi(x),\tfrac{\zeta}{\gamma})] \subseteq B(x,\zeta), \quad \phi[B(x,\zeta)] \supseteq B(\phi(x),\tfrac{\zeta}{\gamma})$$

for every $x \in \mathbb{R}^r$, $\zeta \geq 0$.

(a) If $A \subseteq \mathbb{R}^r$ and $x \in \text{cl}^*A$, set

$$\epsilon = \frac{1}{2}\limsup_{\zeta\downarrow 0} \frac{\mu^*(B(x,\zeta)\cap A}{\mu B(x,\zeta)} > 0.$$

Take any $\zeta_0 > 0$. Then there is a ζ such that $0 < zeta \leq \zeta_0$ and $\mu^*(B(x,\frac{\zeta}{\gamma}) \cap A)] \geq \epsilon\mu B(x,\frac{\zeta}{\gamma})$, so that

$$\mu^*(B(\phi(x),\zeta) \cap \phi[A]) \geq \mu^*\phi[B(x,\tfrac{\zeta}{\gamma}) \cap A] \geq \epsilon\mu B(x,\tfrac{\zeta}{\gamma}) = \frac{\epsilon}{\gamma^r}\mu B(\phi(x),\zeta).$$

As ζ_0 is arbitrary,

$$\limsup_{\zeta\downarrow 0} \frac{\mu^*(B(\phi(x),\zeta)\cap\phi[A]}{\mu B(\phi(x),\zeta)} \geq \frac{\epsilon}{\gamma^r} > 0,$$

and $\phi(x) \in \text{cl}^*(\phi[A])$.

This shows that $\phi[\text{cl}^*A] \subseteq \text{cl}^*(\phi[A])$. The same argument applies to ϕ^{-1} and $\phi[A]$, so that $\phi[\text{cl}^*A]$ must be equal to $\text{cl}^*(\phi[A])$. Taking complements, $\phi[\text{int}^*A] = \text{int}^*(\phi[A])$, so that $\phi[\partial^*A] = \partial^*(\phi[A])$.

(b) Take $C \in \mathcal{C}$. Then, for any $n \in \mathbb{N}$, $\phi^{-1}[B(\mathbf{0}, n)]$ is bounded, so is included in $B(\mathbf{0}, m)$ for some m. Now

$$\begin{aligned}\nu(\partial^*\phi[C] \cap B(\mathbf{0}, n)) &= \nu(\phi[\partial^*C] \cap B(\mathbf{0}, n)) \\ &\leq \nu(\phi[\partial^*C \cap B(\mathbf{0}, m)]) \leq \gamma^{r-1}\nu(\partial^*C \cap B(\mathbf{0}, m))\end{aligned}$$

(264G/471J), so is finite. This shows that $\phi[C]$ has locally finite perimeter and belongs to $\mathcal{C}$. Since $\phi[V]$ is bounded whenever V is bounded, $\phi[V] \in \mathcal{V}$ whenever $V \in \mathcal{V}$.

(c) Set $\alpha' = \gamma^{-2r}\alpha$. Note that as γ^2 is a Lipschitz constant for the identity map, $\gamma \geq 1$, and $\gamma^{2-2r}\alpha \leq \alpha' \leq \alpha$. If $C \in \mathcal{C}_\alpha$, then

$$\begin{aligned}\mu\phi[C] &\geq \frac{1}{\gamma^r}\mu C \geq \frac{\alpha}{\gamma^r}(\operatorname{diam} C)^r \\ &\geq \frac{1}{\alpha}(\frac{1}{\gamma}\operatorname{diam}\phi[C])^r \geq \alpha'(\operatorname{diam}\phi[C])^r,\end{aligned}$$

$$\begin{aligned}\operatorname{per}\phi[C] &= \nu(\partial^*(\phi[C])) = \nu(\phi[\partial^*C]) \leq \gamma^{r-1}\nu(\partial^*C) \\ &\leq \frac{\gamma^{r-1}}{\alpha}(\operatorname{diam} C)^{r-1} \leq \frac{\gamma^{r-1}}{\alpha}(\gamma\operatorname{diam}\phi[C])^{r-1} \leq \frac{1}{\alpha'}(\operatorname{diam}\phi[C])^{r-1}.\end{aligned}$$

So $C \in \mathcal{C}_{\alpha'}$.

If now $\boldsymbol{t} \in T_\alpha$, then, for any $(x, C) \in \boldsymbol{t}$, $\phi[C] \in \mathcal{C}_{\alpha'}$ and $\phi(x) \in \text{cl}^*\phi[C]$; also, because ϕ is injective, $\langle\phi[C]\rangle_{(x,C)\in\boldsymbol{t}}$ is disjoint, so $\{(\phi(x), \phi[C]) : (x, C) \in \boldsymbol{t}\} \in T_{\alpha'}$.

(d) Express $\mathcal{R}$ as $\mathcal{R}_\eta^{(V)}$ where $V \in \mathcal{V}$ and $\eta \in \text{H}$, so that $R \in \mathcal{R}$ whenever $R \cap V \in \mathcal{R}$. By 484Ec and 481He, there is a sequence $\langle\mathcal{Q}_i\rangle_{i\in\mathbb{N}}$ in $\mathfrak{R}$ such that $\bigcup_{i\leq n} A_i \in \mathcal{R}$ whenever $n \in \mathbb{N}$, $\langle A_i\rangle_{i\leq n}$ is disjoint and $A_i \in \mathcal{Q}_i$ for every i. By 484E(b-ii), there is an $\eta' \in \text{H}$ such that $R \in \mathcal{Q}_i$ whenever $i \in \mathbb{N}$ and R is such that $\mu R \leq \gamma^r\eta'(i)$ and $\operatorname{per} R \leq \gamma^{r-1}$. Try $\mathcal{R}' = \mathcal{R}_{\eta'}^{(\phi^{-1}[V])} \in \mathfrak{R}$. If $R \in \mathcal{R}'$, we can express $R \cap \phi^{-1}[V]$ as $\bigcup_{i\leq n} E_i$ where $\operatorname{per} E_i \leq 1$ and $\mu E_i \leq \eta'_i$ for each $i \leq n$, and $\langle E_i\rangle_{i\leq n}$ is disjoint. So $\phi[R] \cap V = \bigcup_{i\leq n}\phi[E_i]$ and $\langle\phi[E_i]\rangle_{i\leq n}$ is disjoint. Now, for each i,

$$\mu\phi[E_i] \leq \gamma^r\mu E_i \leq \gamma^r\eta'(i), \quad \operatorname{per}\phi[E_i] \leq \gamma^{r-1}\operatorname{per} E_i \leq \gamma^{r-1},$$

so $\phi[E_i] \in \mathcal{Q}_i$. By the choice of $\langle\mathcal{Q}_i\rangle_{i\in\mathbb{N}}$, $\phi[R] \cap V \in \mathcal{R}$ and $\phi[R] \in \mathcal{R}$. So $\mathcal{R}'$ has the property we need.

(e) We have only to observe that if A is the thin set $\theta^{-1}[\{0\}]$, then $(\theta\phi)^{-1}[\{0\}] = \phi^{-1}[A]$ is also thin. **P** If $A = \bigcup_{n\in\mathbb{N}} A_n$ where ν^*A_n is finite for every n, then $\phi^{-1}[A] = \bigcup_{n\in\mathbb{N}}\phi^{-1}[A_n]$, while $\nu^*\phi^{-1}[A_n] \leq \gamma^{r-1}\nu^*A_n$ (264G/471J) is finite for every $n \in \mathbb{N}$. **Q**

484S Theorem Let $\phi : \mathbb{R}^r \to \mathbb{R}^r$ be a lipeomorphism. Let H be the set of points at which ϕ is differentiable. For $x \in H$, write $T(x)$ for the derivative of ϕ at x; set $J(x) = |\det T(x)|$ for $x \in H$, 0 for $x \in \mathbb{R}^r \setminus H$. Then, for any function $f : \mathbb{R}^r \to \mathbb{R}^r$,

$$\int f = \int J \times f\phi$$

if either is defined in $\mathbb{R}$.

proof (a) Let $H' \subseteq H$ be a conegligible set such that

$$\begin{aligned}J(x) &= \lim_{\zeta\downarrow 0}\sup\{\frac{\mu\phi[C]}{\mu C} : C \in \mathcal{C}_\alpha,\ x \in \overline{C},\ 0 < \operatorname{diam} C \leq \zeta\} \\ &= \lim_{\zeta\downarrow 0}\inf\{\frac{\mu\phi[C]}{\mu C} : C \in \mathcal{C}_\alpha,\ x \in \overline{C},\ 0 < \operatorname{diam} C \leq \zeta\}\end{aligned}$$

for every $\alpha > 0$ and every $x \in H'$ (484P). To begin with (down to the end of (c)), suppose that f is Pfeffer integrable and that $f\phi(x) = 0$ for every $x \in \mathbb{R}^r \setminus H'$. Let F be the Saks-Henstock indefinite integral of f, and define $G : \mathcal{C} \to \mathbb{R}$ by setting $G(C) = F(\phi[C])$ for every $C \in \mathcal{C}$ (using 484Rb to see that this is well-defined).

(b) G and $J \times f\phi$ satisfy the conditions of 484J.

P (i) Of course G is additive, because F is.

(ii) Suppose that $0 < \alpha < \alpha^*$ and $\epsilon > 0$. Let $\alpha' \in]0, \alpha^*[$ be such that $\{(\phi(x), \phi[C]) : (x, C) \in \boldsymbol{t}\} \in T_{\alpha'}$ whenever $\boldsymbol{t} \in T_\alpha$ (484Rc). Let $\theta_1 \in \Theta$ be such that $\sum_{(x,C)\in\boldsymbol{t}} |F(C) - f(x)\mu C| \leq \frac{1}{2}\epsilon$ for every δ_{θ_1}-fine $\boldsymbol{t} \in T_{\alpha'}$. Let $\theta_2 : \mathbb{R}^r \to]0, 1]$ be such that whenever $x \in H'$ and $n \leq \|x\| + |f\phi(x)| < n + 1$ then

$$|\mu\phi[C] - J(x)\mu C| \leq \frac{\mu C}{2^{n+3}\beta_r(n+2)^r(n+1)}$$

whenever $C \in \mathcal{C}_{\alpha'}$, $x \in \overline{C}$ and $\operatorname{diam} C \leq 2\theta_2(x)$. Set $\theta(x) = \min(\frac{1}{\gamma}\theta_1\phi(x), \theta_2(x))$ for $x \in \mathbb{R}^r$, so that $\theta \in \Theta$ (484Re).

If $\boldsymbol{t} \in T_\alpha$ is δ_θ-fine, set $\boldsymbol{t}' = \{(\phi(x), \phi[C]) : (x, C) \in \boldsymbol{t}\}$. Then $\boldsymbol{t} \in T_{\alpha'}$, by the choice of α'. If $(x, C) \in \boldsymbol{t}$, then $\theta(x) > 0$ so $\theta_1\phi(x) > 0$; also $C \subseteq B(x, \theta(x))$ so

$$\phi[C] \subseteq B(\phi(x), \gamma\theta(x)) \subseteq B(\phi(x), \theta_1\phi(x)).$$

This shows that $\boldsymbol{t}'$ is δ_{θ_1}-fine. We therefore have

$$\begin{aligned}
\sum_{(x,C)\in\boldsymbol{t}} |G(C) - J(x)f(\phi(x))\mu C| &\leq \sum_{(x,C)\in\boldsymbol{t}} |F(\phi[C]) - f(\phi(x))\mu\phi[C]| \\
&\qquad + \sum_{(x,C)\in\boldsymbol{t}} |f(\phi(x))||\mu\phi[C] - J(x)\mu C| \\
&\leq \sum_{(x,C)\in\boldsymbol{t}'} |F(C) - f(x)\mu C| \\
&\qquad + \sum_{\substack{(x,C)\in\boldsymbol{t} \\ x\in H'}} |f(\phi(x))||\mu\phi[C] - J(x)\mu C|
\end{aligned}$$

(because if $x \notin H'$ then $f(\phi(x)) = 0$)

$$\begin{aligned}
&\leq \tfrac{1}{2}\epsilon + \sum_{n=0}^{\infty} \sum_{\substack{(x,C)\in\boldsymbol{t}, x\in H' \\ n\leq\|x\|+|f(\phi(x))|<n+1}} \frac{(n+1)\mu C}{2^{n+3}\beta_r(n+2)^r(n+1)} \\
&\leq \tfrac{1}{2}\epsilon + \sum_{n=0}^{\infty} \frac{(n+1)\mu B(\mathbf{0}, n+2)}{2^{n+3}\beta_r(n+2)^r(n+1)}
\end{aligned}$$

(remembering that $\theta_2(x) \leq 1$, so $C \subseteq B(\mathbf{0}, n+2)$ whenever $(x, C) \in \boldsymbol{t}$ and $\|x\| < n + 1$)

$$= \epsilon.$$

As $\boldsymbol{t}$ is arbitrary, this shows that G and $J \times f\phi$ satisfy (ii) of 484J.

(iii) Given $\epsilon > 0$, there is an $\mathcal{R} \in \mathfrak{R}$ such that $|F(C)| \leq \epsilon$ for every $C \in \mathcal{C} \cap \mathcal{R}$. Now by 484Rd there is an $\mathcal{R}' \in \mathfrak{R}$ such that $\phi[C] \in \mathcal{R}$ for every $R \in \mathcal{R}'$, so that $|G(C)| \leq \epsilon$ for every $C \in \mathcal{C} \cap \mathcal{R}'$. Thus G satisfies (iii) of 484J. **Q**

(c) This shows that $J \times f\phi$ is Pfeffer integrable, with Saks-Henstock indefinite integral G; so, in particular,

$$\text{Pf} \int f \times \phi = G(\mathbb{R}^r) = F(\mathbb{R}^r) = \text{Pf} \int f.$$

(d) Now suppose that f is an arbitrary Pfeffer integrable function. In this case set $f_1 = f \times \chi\phi[H']$. Because $\mathbb{R}^r \setminus H'$ is μ-negligible, so is $\phi[\mathbb{R}^r \setminus H']$, and $f_1 = f$ μ-a.e. Also, of course, $f\phi = f_1\phi$ μ-a.e. Because the Pfeffer integral extends the Lebesgue integral (484He),

$$\text{⨍}\!\!\!\!\!\!\int J \times f\phi = \text{⨍}\!\!\!\!\!\!\int J \times f_1\phi = \text{⨍}\!\!\!\!\!\!\int f_1 = \text{⨍}\!\!\!\!\!\!\int f.$$

(e) All this has been on the assumption that f is Pfeffer integrable. If $g = J \times f\phi$ is Pfeffer integrable, consider $\tilde{J} \times g\phi^{-1}$, where $\tilde{J}(x) = |\det \tilde{T}(x)|$ whenever the derivative $\tilde{T}(x)$ of ϕ^{-1} at x is defined, and otherwise is zero. Now

$$\tilde{J}(x)g(\phi^{-1}(x)) = \tilde{J}(x) \cdot J(\phi^{-1}(x))f(x)$$

for every x. But, for μ-almost every x,

$$\tilde{J}(x)J(\phi^{-1}(x)) = |\det \tilde{T}(x)||\det T(\phi^{-1}(x))| = |\det \tilde{T}(x)T(\phi^{-1}(x))| = 1$$

because $\tilde{T}(x)T(\phi^{-1}(x))$ is (whenever it is defined) the derivative at $\phi^{-1}(x)$ of the identity function $\phi^{-1}\phi$, by 473Bc. (I see that we need to know that $\{x : \phi \text{ is differentiable at } \phi^{-1}(x)\} = \phi[H]$ is conegligible.) So $\tilde{J} \times g\phi^{-1} = f$ μ-a.e., and f is Pfeffer integrable. This completes the proof.

484X Basic exercises (a) Show that for every $\mathcal{R} \in \mathfrak{R}$ there are $\eta \in \mathrm{H}$ and $n \in \mathbb{N}$ such that $\mathcal{R}_\eta^{(B(\mathbf{0},n))} \subseteq \mathcal{R}$.

>(b) (Pfeffer 91a) For $\alpha > 0$ let $\mathcal{C}'_\alpha$ be the family of bounded Lebesgue measurable sets C such that $\mu C \geq \alpha \operatorname{diam} C \operatorname{per} C$, and T'_α the straightforward set of tagged partitions generated by $\{(x, C) : C \in \mathcal{C}'_\alpha, x \in \mathrm{cl}^* C\}$. (i) Show that if $\alpha' = \min(\alpha^r, 2^{-r}\beta_r/\alpha)$ then $\mathcal{C}_{\alpha^2} \subseteq \mathcal{C}'_\alpha \subseteq \mathcal{C}_\alpha$. (*Hint*: 474La.) (ii) Show that T'_α is compatible with Δ and $\mathfrak{R}$ whenever $0 < \alpha < 1/2r\sqrt{r}$.

>(c) For $\alpha > 0$, let $\mathcal{C}''_\alpha$ be the family of convex sets C such that $\mu C \geq \alpha(\operatorname{diam} C)^r$. Show that $\mathcal{C}''_\alpha \subseteq \mathcal{C}_\alpha$. (*Hint*: 475T.) Show that if $0 < \alpha < \dfrac{2^{r-1}}{r\beta_r}$ and $T''_\alpha = T_\alpha \cap [\mathbb{R}^r \times \mathcal{C}'_\alpha]^{<\omega}$ then T''_α is compatible with Δ and $\mathfrak{R}$. (*Hint*: use the argument of 484F, but in part (b) take $C \in \mathcal{D}$.)

(d) Describe a suitable filter $\mathcal{F}$ to express the Pfeffer integral directly in the form considered in 481C.

(e) Let $f : \mathbb{R}^r \to \mathbb{R}$ be a Pfeffer integrable function. Show that there is some $n \in \mathbb{N}$ such that $\int_{\mathbb{R}^r \setminus B(\mathbf{0},n)} |f| d\mu$ is finite.

(f) Let $E \subseteq \mathbb{R}^r$ be a bounded set with finite perimeter, and $\phi : \mathbb{R}^r \to \mathbb{R}^r$ a differentiable function. Let v_x be the Federer exterior normal to E at any point x where the normal exists. Show that $\text{⨍}\!\!\!\!\!\!\int \operatorname{div} \phi \times \chi E$ is defined and equal to $\int_{\partial^* E} \phi(x) \cdot v_x \nu(dx)$.

484Y Further exercises (a) Let $E \subseteq \mathbb{R}^r$ be any Lebesgue measurable set, and $\epsilon > 0$. Show that there is a Lebesgue measurable set $G \subseteq E$ such that $\operatorname{per} G \leq \operatorname{per} E$, $\mu(E \setminus G) \leq \epsilon$ and $\mathrm{cl}^* G = \overline{G}$.

(b) Give an example of a compact set $K \subseteq \mathbb{R}^2$ with zero one-dimensional Hausdorff measure such that whenever $\theta : K \to]0, \infty[$ is a strictly positive function, and $\gamma \in \mathbb{R}$, there is a disjoint family $\langle B(x_i, \zeta_i)\rangle_{i \leq n}$ of balls such that $x_i \in K$ and $\zeta_i \leq \theta(x_i)$ for every i, while $\operatorname{per}(\bigcup_{i \leq n} B(x_i, \zeta_i)) \geq \gamma$.

484 Notes and comments Observe that 484B can be thought of as a refinement of 475I. As usual, the elaborate formula in the statement of 484C is there only to emphasize that we have a constant depending only on r.

The whole point of 'gauge integrals' is that we have an enormous amount of freedom within the framework of §§481-482. There is a corresponding difficulty in making exact choices. The essential ideology of the 'Pfeffer integral' is that we take an intersection of a family of gauge integrals, each determined by a family $\mathcal{C}_\alpha$ of sets which are 'Saks regular' in the sense that their measures, perimeters and diameters are linked. Shrinking $\mathcal{C}_\alpha$ and T_α, while leaving Δ and $\mathfrak{R}$ unchanged, of course leads to a more 'powerful' integral (supposing, at least, that we do not go so far that T_α is no longer compatible with Δ and $\mathfrak{R}$), so that Pfeffer's Divergence Theorem will remain true. One possibility is to turn to convex sets (484Xc).

Similar technical questions arise when choosing the family $\mathfrak{R}$ of residual classes. Here I use the construction $\mathcal{R}_\eta^{(V)} = \{R : R \cap V \in \mathcal{R}_\eta\}$ (484D) as a quick method of eliminating any difficulties at infinity (484Xe).

We do not of course need to look at arbitrary sets $V \in \mathcal{V}$ here (484Xa). One of the important simplifications in the one-dimensional theory is that we can work with a very much simpler family of residual classes; this is because 'thin' sets become countable (see 484Xf), and can be controlled by neighbourhood gauges. I give 484Yb as a pointer to the problems which arise if we do not exclude thin sets by the device of allowing the gauge functions θ to be zero on such sets, thereby removing some potential tags.

The many equivalent formulations of the Denjoy-Perron-Henstock integral challenge us to seek corresponding descriptions of integrals on $\mathbb{R}^r$. 484O shows that we can express a Pfeffer integrable function as the derivative almost everywhere (in a strong sense) of its Saks-Henstock indefinite integral.

I include 484S as a worked example on the techniques already developed. Note that it depends much more on the fact that the Pfeffer integral can be characterized in the language of 475J, than on the exact choices made in forming $\mathfrak{R}$ and the $\mathcal{C}_\alpha$. (Of course if we restricted the C_α to the point that they contained only convex sets, we could not expect invariance under lipeomorphisms.) For a discussion of integrals *defined* by Saks-Henstock lemmas, see Pfeffer 01.

Chapter 49

Further topics

I conclude the volume with notes on five almost unconnected special topics. In §491 I look at equidistributed sequences and the ideal $\mathcal{Z}$ of sets with asymptotic density zero. I give the principal theorems on the existence of equidistributed sequences in abstract topological measure spaces, and examine the way in which an equidistributed sequence induces an embedding of a measure algebra in the quotient algebra $\mathcal{P}\mathbb{N}/\mathcal{Z}$. In §492 I present some forms of 'concentration of measure' which echo ideas from §476 in combinatorial, rather than geometric, contexts, with theorems of Talagrand and Maurey on product measures and the Haar measure of a permutation group. In §493 I show how the ideas of §§449, 476 and 492 can be put together in the theory of 'extremely amenable' topological groups. In §494, I give a pair of simple, but surprising, results on subsets of sets of positive measure in product spaces. Finally, in §495, I introduce Poisson point processes, with notes on disintegrations and some special cases in which they can be represented by Radon measures.

491 Equidistributed sequences

In many of the most important topological measure spaces, starting with Lebesgue measure (491Xf), there are sequences which are equidistributed in the sense that, in the limit, they spend the right proportion of their time in each part of the space (491Ye). I give the basic results on existence of equidistributed sequences in 491E-491G and 491Q. Investigating such sequences, we are led to some interesting properties of the asymptotic density ideal $\mathcal{Z}$ and the quotient algebra $\mathfrak{Z} = \mathcal{P}\mathbb{N}/\mathcal{Z}$ (491A, 491I-491K). For 'effectively regular' measures (491L-491M), equidistributed sequences lead to embeddings of measure algebras in $\mathfrak{Z}$ (491N).

491A The asymptotic density ideal (a) If $I \subseteq \mathbb{N}$, its **upper asymptotic density** is $d^*(I) = \limsup_{n\to\infty} \frac{1}{n}(I \cap n)$, and its **asymptotic density** is $d(I) = \lim_{n\to\infty} \frac{1}{n}\#(I \cap n)$ if this is defined. It is easy to check that d^* is a submeasure on $\mathcal{P}\mathbb{N}$ (definition: 392A), so that

$$\mathcal{Z} = \{I : I \subseteq \mathbb{N},\, d^*(I) = 0\} = \{I : I \subseteq \mathbb{N},\, d(I) = 0\}$$

is an ideal, the **asymptotic density ideal**.

(b) Note that

$$\mathcal{Z} = \{I : I \subseteq \mathbb{N},\, \lim_{n\to\infty} 2^{-n}\#(I \cap 2^{n+1} \setminus 2^n) = 0\}.$$

P If $I \subseteq \mathbb{N}$ and $d^*(I) = 0$, then

$$2^{-n}\#(I \cap 2^{n+1} \setminus 2^n) \leq 2 \cdot 2^{-n-1}\#(I \cap 2^{n+1}) \to 0$$

as $n \to \infty$. In the other direction, if $\lim_{n\to\infty} 2^{-n}\#(I \cap 2^{n+1} \setminus 2^n) = 0$, then for any $\epsilon > 0$ there is an $m \in \mathbb{N}$ such that $\#(I \cap 2^{k+1} \setminus 2^k) \leq 2^k\epsilon$ for every $k \geq m$. In this case, for $n \geq 2^m$, take k_n such that $2^{k_n} \leq n < 2^{k_n+1}$, and see that

$$\frac{1}{n}\#(I \cap n) \leq 2^{-k_n}(\#(I \cap 2^m) + \textstyle\sum_{k=m}^{k_n} 2^k\epsilon) \leq 2^{-k_n}\#(I \cap 2^m) + 2\epsilon \to 2\epsilon$$

as $n \to \infty$, and $d^*(I) \leq 2\epsilon$; as ϵ is arbitrary, $I \in \mathcal{Z}$. **Q**

(c) Writing $\mathcal{D}$ for the domain of d,

$$\begin{aligned}\mathcal{D} &= \{I : I \subseteq \mathbb{N},\, \limsup_{n\to\infty} \frac{1}{n}\#(I \cap n) = \liminf_{n\to\infty} \frac{1}{n}\#(I \cap n)\}\\ &= \{I : I \subseteq \mathbb{N},\, d^*(I) = 1 - d^*(\mathbb{N} \setminus I)\},\end{aligned}$$

$$\mathbb{N} \in \mathcal{D}, \quad \text{if } I,\, J \in \mathcal{D} \text{ and } I \subseteq J \text{ then } J \setminus I \in \mathcal{D},$$

$$\text{if } I,\, J \in \mathcal{D} \text{ and } I \cap J = \emptyset \text{ then } I \cup J \in \mathcal{D} \text{ and } d(I \cup J) = d(I) + d(J).$$

It follows that if $\mathcal{I} \subseteq \mathcal{D}$ and $I \cap J \in \mathcal{I}$ for all $I,\, J \in \mathcal{I}$, then the subalgebra of $\mathcal{P}\mathbb{N}$ generated by $\mathcal{I}$ is included in $\mathcal{D}$ (313Ga). But note that $\mathcal{D}$ itself is *not* a subalgebra of $\mathcal{P}\mathbb{N}$ (491Xa).

(d) The following elementary fact will be useful. If $\langle l_n\rangle_{n\in\mathbb{N}}$ is a strictly increasing sequence in $\mathbb{N}$ such that $\lim_{n\to\infty} l_{n+1}/l_n = 1$, and $I \subseteq \mathbb{R}$, then

$$d^*(I) \leq \limsup_{n\to\infty} \frac{1}{l_{n+1}-l_n}\#(I \cap l_{n+1} \setminus l_n).$$

P Set $\gamma = \limsup_{n\to\infty} \frac{1}{l_{n+1}-l_n}\#(I \cap l_{n+1} \setminus l_n)$, and take $\epsilon > 0$. Let n_0 be such that $\#(I \cap l_{n+1} \setminus l_n) \leq (\gamma+\epsilon)(l_{n+1}-l_n)$ and $l_{n+1} - l_n \leq \epsilon l_n$ for every $n \geq n_0$, and write M for $\#(I \cap l_{n_0})$. If $m > l_{n_0}$, take k such that $l_k \leq m < l_{k+1}$; then

$$\begin{aligned}\#(I \cap m) &\leq M + \sum_{n=n_0}^{k-1} \#(I \cap l_{n+1} \setminus l_n) + (m - l_k)\\ &\leq M + \sum_{n=n_0}^{k-1} (\gamma+\epsilon)(l_{n+1}-l_n) + l_{k+1} - l_k \leq M + m(\gamma+\epsilon) + \epsilon m,\end{aligned}$$

so

$$\frac{1}{m}\#(I \cap m) \leq \frac{M}{m} + \gamma + 2\epsilon.$$

Accordingly $d^*(I) \leq \gamma + 2\epsilon$; as ϵ is arbitrary, $d^*(I) \leq \gamma$. **Q**

491B Equidistributed sequences Let X be a topological space and μ a probability measure on X. I say that a sequence $\langle x_n\rangle_{n\in\mathbb{N}}$ in X is **(asymptotically) equidistributed** or **uniformly distributed** if $\mu F \geq d^*(\{i : x_i \in F\})$ for every measurable closed set $F \subseteq X$; equivalently, if $\mu G \leq \liminf_{n\to\infty} \frac{1}{n}\#(\{i : i < n,\ x_i \in G\})$ for every measurable open set $G \subseteq X$.

Remark Traditionally, equidistributed sequences have been defined in terms of their action on continuous functions, as in 491Cf. I have adopted the definition here in order to deal both with Radon measures on spaces which are not completely regular (so that we cannot identify the measure with an integral) and with Baire measures (so that there may be closed sets which are not measurable). Note that we cannot demand that the sets $\{i : x_i \in F\}$ should have well-defined densities (491Xh).

491C I work through a list of basic facts. The technical details (if we do not specialize immediately to metrizable or compact spaces) are not quite transparent, so I set them out carefully.

Proposition Let X be a topological space, μ a probability measure on X and $\langle x_n\rangle_{n\in\mathbb{N}}$ a sequence in X. Write $C_b(X)$ for the space of bounded continuous real-valued functions on X.

(a) $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed iff $\int f d\mu \leq \liminf_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^n f(x_i)$ for every measurable bounded lower semi-continuous function $f : X \to \mathbb{R}$.

(b) If μ measures every zero set and $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed, then $\lim_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^n f(x_i) = \int f d\mu$ for every $f \in C_b(X)$.

(c) Suppose that μ measures every zero set in X. If $\lim_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^n f(x_i) = \int f d\mu$ for every $f \in C_b(X)$, then $d^*(\{n : x_n \in F\}) \leq \mu F$ for every zero set $F \subseteq X$.

(d) Suppose that X is normal and that μ measures every zero set and is inner regular with respect to the closed sets. If $\lim_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^n f(x_i) = \int f d\mu$ for every $f \in C_b(X)$, then $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed.

(e) Suppose that μ is τ-additive and there is a base $\mathcal{G}$ for the topology of X, consisting of measurable sets and closed under finite unions, such that $\mu G \leq \liminf_{n\to\infty} \frac{1}{n+1}\#(\{i : i \leq n,\ x_i \in G\})$ for every $G \in \mathcal{G}$. Then $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed.

(f) Suppose that X is completely regular and that μ measures every zero set and is τ-additive. Then $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed iff $\lim_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^n f(x_i) = \int f d\mu$ for every $f \in C_b(X)$.

(g) Suppose that X is metrizable and that μ is a topological measure. Then $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed iff $\lim_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^n f(x_i) = \int f d\mu$ for every $f \in C_b(X)$.

(h) Suppose that X is compact, Hausdorff and zero-dimensional, and that μ is a Radon measure on X. Then $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed iff $d(\{n : x_n \in G\}) = \mu G$ for every open-and-closed subset G of X.

proof (a)(i) Suppose that $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed. Let $f : X \to [0,1]$ be a measurable lower semi-continuous function and $k \geq 1$. For each $j < k$ set $G_j = \{x : f(x) > \frac{j}{k}\}$. Then

$$\liminf_{n\to\infty} \frac{1}{n+1}\sum_{j=1}^{n} \chi G_j(x_i) = \liminf_{n\to\infty} \frac{1}{n+1}\#(\{i : i \leq n,\, x_i \in G_j\}) \geq \mu G_j$$

because $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed and G_j is a measurable open set. Also $f - \frac{1}{k}\chi X \leq \frac{1}{k}\sum_{j=1}^{k} \chi G_j \leq f$, so

$$\begin{aligned}\int f d\mu - \frac{1}{k} &\leq \frac{1}{k}\sum_{j=1}^{k} \mu G_j \leq \frac{1}{k}\sum_{j=1}^{k} \liminf_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n} \chi G_j(x_i)\\ &\leq \frac{1}{k}\liminf_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n}\sum_{j=1}^{k} \chi G_j(x_i) \leq \liminf_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n} f(x_i).\end{aligned}$$

As k is arbitrary, $\int f d\mu \leq \liminf_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n} f(x_i)$.

The argument above depended on f taking values in $[0,1]$. But multiplying by an appropriate positive scalar we see that $\int f d\mu \leq \liminf_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n} f(x_i)$ for every bounded measurable lower semi-continuous $f : X \to [0,\infty[$, and adding a multiple of χX we see that the same formula is valid for all bounded measurable lower semi-continuous $f : X \to \mathbb{R}$.

(ii) Conversely, if $\int f d\mu \leq \liminf_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n} f(x_i)$ for every bounded measurable lower semi-continuous $f : X \to \mathbb{R}$, and $G \subseteq X$ is a measurable open set, then χG is lower semi-continuous, so $\mu G \leq \liminf_{n\to\infty} \frac{1}{n+1}\#(\{i : i \leq n,\, x_i \in G\})$. As G is arbitrary, $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed.

(b) Apply (a) to the lower semi-continuous functions f and $-f$.

(c) Recall that if μ measures every zero set, then every bounded continuous real-valued function is integrable, by 4A3L. Let $F \subseteq X$ be a zero set, and $\epsilon > 0$. Then there is a continuous $f : X \to \mathbb{R}$ such that $F = f^{-1}[\{0\}]$. Let $\delta > 0$ be such that $\mu\{x : 0 < |f(x)| \leq \delta\} \leq \epsilon$, and set $g = (\chi X - \frac{1}{\delta}|f|)^+$. Then $g : X \to [0,1]$ is continuous and $\chi F \leq g$, so

$$\begin{aligned}d^*(\{n : x_n \in F\}) &\leq \limsup_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n} g(x_i)\\ &= \int g\, d\mu \leq \mu\{x : |f(x)| \leq \delta\} \leq \mu F + \epsilon.\end{aligned}$$

As ϵ and F are arbitrary, we have the result.

(d) Let $F \subseteq X$ be a measurable closed set and $\epsilon > 0$. Because μ is inner regular with respect to the closed sets, there is a measurable closed set $F' \subseteq X \setminus F$ such that $\mu F' \geq \mu(X \setminus F) - \epsilon$. Because X is normal, there is a continuous function $f : X \to [0,1]$ such that $\chi F \leq f \leq \chi(X \setminus F')$. Now

$$d^*(\{n : x_n \in F\}) \leq \limsup_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n} f(x_i) = \int f d\mu \leq \mu(X \setminus F') \leq \mu F + \epsilon.$$

As F and ϵ are arbitrary, $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed.

(e) Let $F \subseteq X$ be a measurable closed set, and $\epsilon > 0$. Let $\mathcal{G}_1$ be the family of members of $\mathcal{G}$ disjoint from F. Then $\mathcal{G}_1$ is upwards-directed and $\bigcup \mathcal{G}_1 = X \setminus F$; because μ is τ-additive, there is a $G \in \mathcal{G}_1$ such that $\mu G > \mu(X \setminus F) - \epsilon$. Now

$$\begin{aligned}d^*(\{n : x_n \in F\}) &\leq \limsup_{n\to\infty} \frac{1}{n+1}\#(\{i : i \leq n,\, x_i \in X \setminus G\})\\ &= 1 - \liminf_{n\to\infty} \frac{1}{n+1}\#(\{i : i \leq n,\, x_i \in G\}) \leq 1 - \mu G \leq \mu F + \epsilon.\end{aligned}$$

As F and ϵ are arbitrary, $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed.

(f) (i) If $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed then (b) tells us that $\int f d\mu = \lim_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n} f(x_i)$ for every $f \in C_b(X)$. (ii) Suppose that $\int f d\mu = \lim_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n} f(x_i)$ for every $f \in C_b(X)$. If $G \subseteq X$ is a cozero

set, we can apply (c) to its complement to see that $\mu G \leq \liminf_{n\to\infty} \frac{1}{n+1}\#(\{i : i \leq n, x_i \in G\})$. So applying (e) with $\mathcal{G}$ the family of cozero sets we see that $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed.

(g) Because every closed set is a zero set, this follows at once from (b) and (c).

(h) If $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed and $G \subseteq X$ is open-and-closed, then $d^*(\{n : x_n \in G\}) \leq \mu G$ because G is closed and $d^*(\{n : x_n \notin G\}) \leq 1 - \mu G$ because G is open; so $d(\{n : x_n \in G\}) = \mu G$. If the condition is satisfied, then (e) tells us that $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed.

491D The next lemma provides a useful general criterion for the existence of equidistributed sequences.

Lemma Let X be a topological space and μ a probability measure on X. Suppose that there is a sequence $\langle \nu_n\rangle_{n\in\mathbb{N}}$ of point-supported probability measures on X such that $\mu F \geq \limsup_{n\to\infty} \nu_n F$ for every measurable closed set $F \subseteq X$. Then μ has an equidistributed sequence.

proof For each $n \in \mathbb{N}$, let $q_n : X \to [0,1]$ be such that $\nu_n E = \sum_{x\in E} q_n(x)$ for every $E \subseteq X$. Let $q'_n : X \to [0,1]$ be such that $\sum_{x\in X} q'_n(x) = 1$, $K_n = \{x : q'_n(x) > 0\}$ is finite, $q'_n(x)$ is rational for every x, and $\sum_{x\in X} |q_n(x) - q'_n(x)| \leq 2^{-n}$; then $\mu F \geq \limsup_{n\to\infty} \nu'_n F$ for every measurable closed F, where ν'_n is defined from q'_n. For each n, let $s_n \geq 1$ be such that $r_n(x) = q'_n(x)s_n$ is an integer for every $x \in K_n$. Let $\langle x_{ni}\rangle_{i<s_n}$ be a family in K_n such that $\#(\{i : i < s_n,\ x_{ni} = x\}) = r_n(x)$ for each $x \in K_n$; then $\nu'_n E = \frac{1}{s_n}\#(\{i : i < s_n, x_{ni} \in E\})$ for every $E \subseteq X$.

Let $\langle m_k\rangle_{k\in\mathbb{N}}$ be such that $s_{k+1} \leq 2^{-k}\sum_{j=0}^{k} m_j s_j$ for each k. Set $l_0 = 0$. Given l_n, take the largest k such that $\sum_{j=0}^{k-1} m_j s_j \leq l_n$; set $l_{n+1} = l_n + s_k$ and $x_i = x_{k,i-l_n}$ for $l_n \leq i < l_{n+1}$; continue. By the choice of the m_k, $l_{n+1}/l_n \to 1$ as $n \to \infty$. For any $E \subseteq X$, $\#(\{i : l_n \leq i < l_{n+1}, x_i \in E\}) = \#(\{j : j < s_k, x_{kj} \in E\})$ whenever $\sum_{j=0}^{k-1} m_j s_j \leq l_n < \sum_{j=0}^{k} m_j s_j$. So for any measurable closed set $F \subseteq X$,

$$\begin{aligned} d^*(\{i : x_i \in F\}) &\leq \limsup_{k\to\infty} \frac{1}{s_k}\#(\{j : j < s_k, x_{kj} \in F\}) \\ &= \limsup_{k\to\infty} \nu'_k F \leq \mu F. \end{aligned} \tag{491Ad}$$

As F is arbitrary, $\langle x_n\rangle_{n\in\mathbb{N}}$ is an equidistributed sequence for μ.

491E Proposition (a)(i) Suppose that X and Y are topological spaces, μ a probability measure on X and $f : X \to Y$ a continuous function. If $\langle x_n\rangle_{n\in\mathbb{N}}$ is a sequence in X which is equidistributed with respect to μ, then $\langle f(x_n)\rangle_{n\in\mathbb{N}}$ is equidistributed with respect to the image measure μf^{-1}.

(ii) Suppose that (X,μ) and (Y,ν) are topological probability spaces and $f : X \to Y$ is a continuous inverse-measure-preserving function. If $\langle x_n\rangle_{n\in\mathbb{N}}$ is a sequence in X which is equidistributed with respect to μ, then $\langle f(x_n)\rangle_{n\in\mathbb{N}}$ is equidistributed with respect to ν.

(b) Let X be a topological space and μ a probability measure on X, and suppose that X has a countable network consisting of sets measured by μ. Let λ be the ordinary product measure on $X^{\mathbb{N}}$. Then λ-almost every sequence $\langle x_n\rangle_{n\in\mathbb{N}}$ in $X^{\mathbb{N}}$ is μ-equidistributed.

proof (a)(i) Let $F \subseteq Y$ be a closed set which is measured by μf^{-1}. Then $f^{-1}[F]$ is a closed set in X measured by μ. So

$$d^*(\{n : f(x_n) \in F\}) = d^*(\{n : x_n \in f^{-1}[F]\}) \leq \mu f^{-1}[F].$$

(ii) Replace 'μf^{-1}' above by 'ν'.

(b) Let $\mathcal{A}$ be a countable network for the given topology $\mathfrak{S}$ of X consisting of measurable sets, and let $\mathcal{E}$ be the countable subalgebra of $\mathcal{P}X$ generated by $\mathcal{A}$. Let $\mathfrak{T} \supseteq \mathfrak{S}$ be the second-countable topology generated by $\mathcal{E}$; then μ is a τ-additive topological measure with respect to $\mathfrak{T}$, and $\mathcal{E}$ is a base for $\mathfrak{T}$ closed under finite unions. If $E \in \mathcal{E}$, then $d(\{n : x_n \in E\}) = \mu E$ for λ-almost every sequence $\langle x_n\rangle_{n\in\mathbb{N}}$ in X, by the strong law of large numbers (273J). So

$$d(\{n : x_n \in E\}) = \mu E \text{ for every } E \in \mathcal{E}$$

for λ-almost every $\langle x_n\rangle_{n\in\mathbb{N}}$. Now 491Ce tells us that any such sequence is equidistributed with respect to $\mathfrak{T}$ and therefore with respect to $\mathfrak{S}$.

491F Theorem Let $\langle (X_i, \mathfrak{T}_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a family of τ-additive topological probability spaces, each of which has an equidistributed sequence. If $\#(I) \leq \mathfrak{c}$, then the τ-additive product measure λ on $X = \prod_{i\in I} X_i$ (definition: 417G) has an equidistributed sequence.

proof (a) For the time being (down to the end of (f)), let us suppose that every μ_m is inner regular with respect to the Borel sets. (This will make it possible to use the theorems of §417, in particular 417H and 417J.)

The formulae of some of the arguments below will be simplified if we immediately re-index the family $\langle (X_i, \mathfrak{T}_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ as $\langle (X_A, \mathfrak{T}_A, \Sigma_A, \mu_A)\rangle_{A\in\mathcal{A}}$ where $\mathcal{A} \subseteq \mathcal{P}\mathbb{N}$. For each $A \in \mathcal{A}$, let $\langle t_{An}\rangle_{n\in\mathbb{N}}$ be an equidistributed sequence in X_A; for $n \in \mathbb{N}$, let ν_{An} be the point-supported measure on X_A defined by setting $\nu_{An}E = \frac{1}{n+1}\#(\{i : i \leq n,\ t_{Ai} \in E\})$ for $E \subseteq X_A$. For each finite set $\mathcal{I} \subseteq \mathcal{A}$, set $Y_{\mathcal{I}} = \prod_{A\in\mathcal{I}} X_A$; set $\pi_{\mathcal{I}}(x) = x{\restriction}\mathcal{I} \in Y_{\mathcal{I}}$ for $x \in X$. Let $\lambda_{\mathcal{I}}$ be the τ-additive product of $\langle \mu_I\rangle_{A\in\mathcal{I}}$ and, for each n, let $\check{\nu}_{\mathcal{I}n}$ be the product of the measures $\langle \nu_{An}\rangle_{A\in\mathcal{I}}$. (Because $\mathcal{I}$ is finite, this is a point-supported probability measure. I do not say 'τ-additive product' here because I do not wish to assume that all singleton sets are Borel, so the ν_{An} may not be inner regular with respect to Borel sets.)

(b) Suppose that $\mathcal{I} \subseteq \mathcal{A}$ is finite and that $W \subseteq Y_{\mathcal{I}}$ is an open set. Then $\lambda_{\mathcal{I}}W \leq \liminf_{n\to\infty} \check{\nu}_{\mathcal{I}n}W$. **P** Induce on $\#(\mathcal{I})$. If $\mathcal{I} = \emptyset$, $Y_{\mathcal{I}}$ is a singleton and the result is trivial. For the inductive step, if $\mathcal{I} \neq \emptyset$, take any $A \in \mathcal{I}$ and set $\mathcal{I}' = \mathcal{I} \setminus \{A\}$. Then we can identify $Y_{\mathcal{I}}$ with $Y_{\mathcal{I}'} \times X_A$, $\lambda_{\mathcal{I}}$ with the τ-additive product of $\lambda_{\mathcal{I}'}$ and μ_A (417J), and each $\check{\nu}_{\mathcal{I}n}$ with the product of $\check{\nu}_{\mathcal{I}'n}$ and ν_{An}.

Let $\mathcal{V}$ be the family of those subsets V of $Y_{\mathcal{I}}$ which are expressible as a finite union of sets of the form $U \times H$ where $U \subseteq Y_{\mathcal{I}'}$ and $H \subseteq X_A$ are open. Then $\mathcal{V}$ is a base for the topology of $Y_{\mathcal{I}}$ closed under finite unions. Let $\epsilon > 0$. Because $\lambda_{\mathcal{I}}$ is τ-additive, there is a $V \in \mathcal{V}$ such that $\lambda_{\mathcal{I}}V \geq \lambda W - \epsilon$. The function $t \mapsto \lambda_{\mathcal{I}'}V[\{t\}] : X_A \to [0,1]$ is lower semi-continuous (417Ba), so 491Ca tells us that

$$\begin{aligned}\lambda_{\mathcal{I}}V &= \int \lambda_{\mathcal{I}'}V[\{t\}]\mu_A(dt)\\ &\leq \liminf_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n} \lambda_{\mathcal{I}'}V[\{t_{Ai}\}] = \liminf_{n\to\infty} \int \lambda_{\mathcal{I}'}V[\{t\}]\nu_{An}(dt).\end{aligned}$$

At the same time, there are only finitely many sets of the form $V[\{t\}]$, and for each of these we have $\lambda_{\mathcal{I}'}V[\{t\}] \leq \liminf_{n\to\infty} \check{\nu}_{\mathcal{I}'n}V[\{t\}]$, by the inductive hypothesis. So there is an $n_0 \in \mathbb{N}$ such that $\lambda_{\mathcal{I}'}V[\{t\}] \leq \check{\nu}_{\mathcal{I}'n}V[\{t\}] + \epsilon$ for every $n \geq n_0$ and every $t \in X_A$. We must therefore have

$$\begin{aligned}\lambda_{\mathcal{I}}W \leq \lambda_{\mathcal{I}}V + \epsilon &\leq \liminf_{n\to\infty} \int \lambda_{\mathcal{I}'}V[\{t\}]\nu_{An}(dt) + \epsilon\\ &\leq \liminf_{n\to\infty} \int \check{\nu}_{\mathcal{I}'n}V[\{t\}]\nu_{An}(dt) + 2\epsilon\\ &= \liminf_{n\to\infty} \check{\nu}_{\mathcal{I}n}V + 2\epsilon \leq \liminf_{n\to\infty} \check{\nu}_{\mathcal{I}n}W + 2\epsilon.\end{aligned}$$

As ϵ and W are arbitrary, the induction proceeds. **Q**

(c) For $K \subseteq m \in \mathbb{N}$, set $\mathcal{A}_{mK} = \{A : A \in \mathcal{A},\ A \cap m = K\}$ and $Z_{mK} = \prod_{A\in\mathcal{A}_{mK}} X_A$. (If $\mathcal{A}_{mK} = \emptyset$ then $Z_{mK} = \{\emptyset\}$.) Then for each $m \in \mathbb{N}$ we can identify X with the finite product $\prod_{K\subseteq m} Z_{mK}$. For $K \subseteq m \in \mathbb{N}$ and $n \in \mathbb{N}$, define $z_{mKn} \in Z_{mK}$ by setting $z_{mKn}(A) = t_{An}$ for $A \in \mathcal{A}_{mK}$; let $\tilde{\nu}_{mKn}$ be the point-supported measure on Z_{mK} defined by setting $\tilde{\nu}_{mKn}W = \frac{1}{n+1}\#(\{i : i \leq n,\ z_{mKi} \in W\})$ for each $W \subseteq Z_{mK}$. For $n \in \mathbb{N}$ let $\tilde{\nu}_n$ be the measure on X which is the product of the measures $\tilde{\nu}_{nKn}$ for $K \subseteq n$; this too is point-supported.

(d) If $\mathcal{I} \subseteq \mathcal{A}$ is finite, there is an $m \in \mathbb{N}$ such that $\check{\nu}_{\mathcal{I}n} = \tilde{\nu}_n\pi_{\mathcal{I}}^{-1}$ for every $n \geq m$. **P** Let m be such that $A \cap m \neq A' \cap m$ for all distinct A, $A' \in \mathcal{I}$. If $n \geq m$, then $\tilde{\nu}_n$ is the product of the $\tilde{\nu}_{nKn}$ for $K \subseteq n$. Now $\pi_{\mathcal{I}}$, interpreted as a function from $\prod_{K\subseteq n} Z_{nK}$ onto $Y_{\mathcal{I}}$, is of the form $\pi_{\mathcal{I}}(\langle z_K\rangle_{K\subseteq n}) = \langle z_{A\cap n}(A)\rangle_{A\in\mathcal{I}}$, so the

image measure $\tilde{\nu}_n\pi_{\mathcal{I}}^{-1}$ is the product of the family $\langle\tilde{\nu}_{n,A\cap n,n}\hat{\pi}_A^{-1}\rangle_{A\in\mathcal{I}}$, writing $\hat{\pi}_A(z) = z(A)$ when $A\cap n = K$ and $z \in Z_{nK}$ (254H, or otherwise). But, looking back at the definitions,

$$\begin{aligned}\tilde{\nu}_{n,A\cap n,n}\hat{\pi}_A^{-1}[E] &= \frac{1}{n+1}\#(\{i : i \le n,\, z_{n,A\cap n,i} \in \hat{\pi}_A^{-1}[E]\})\\ &= \frac{1}{n+1}\#(\{i : i \le n,\, z_{n,A\cap n,i}(A) \in E\})\\ &= \frac{1}{n+1}\#(\{i : i \le n,\, t_{Ai} \in E\}) = \nu_{An}E\end{aligned}$$

for every $E \subseteq X_A$. So $\tilde{\nu}_n\pi_{\mathcal{I}}^{-1}$ is the product of $\langle\nu_{An}\rangle_{A\in\mathcal{I}}$, which is $\check{\nu}_{\mathcal{I}n}$. **Q**

(e) Let $\mathcal{W}$ be the family of those open sets $W \subseteq X$ expressible in the form $\pi_{\mathcal{I}}^{-1}[W']$ for some finite $\mathcal{I} \subseteq \mathcal{A}$ and some open $W' \subseteq Y_{\mathcal{I}}$. If $W \in \mathcal{W}$, then $\lambda W \le \liminf_{n\in\mathbb{N}} \tilde{\nu}_n W$. **P** Take $\mathcal{I} \in [\mathcal{A}]^{<\omega}$ and an open $W' \subseteq Y_{\mathcal{I}}$ such that $W = \pi_{\mathcal{I}}^{-1}[W']$. Then

$$\begin{aligned}\lambda W &= \lambda_{\mathcal{I}} W'\\ &\text{(417K)}\\ &\le \liminf_{n\to\infty} \check{\nu}_{\mathcal{I}n} W'\\ &\text{(by (b) above)}\\ &= \liminf_{n\to\infty} \tilde{\nu}_n \pi_{\mathcal{I}}^{-1}[W']\\ &\text{(by (d))}\\ &= \liminf_{n\to\infty} \tilde{\nu}_n W.\end{aligned}$$

Q

(f) If now $F \subseteq X$ is any closed set and $\epsilon > 0$, then (because $\mathcal{W}$ is a base for the topology of X closed under finite unions) there is a $W \in \mathcal{W}$ such that $W \subseteq X \setminus F$ and $\lambda W \ge 1 - \lambda F + \epsilon$. In this case

$$\limsup_{n\to\infty} \tilde{\nu}_n F \le 1 - \liminf_{n\to\infty} \tilde{\nu}_n W \le 1 - \lambda W \le \lambda F + \epsilon.$$

As ϵ is arbitrary, $\limsup_{n\to\infty} \tilde{\nu}_n F \le \lambda F$; as F is arbitrary, 491D tells us that there is an equidistributed sequence in X.

(g) All this was on the assumption that every μ_i is inner regular with respect to the Borel sets. For the superficially more general case enunciated, given only that each μ_i is a τ-additive topological measure with an equidistributed sequence, let μ_i' be the restriction of μ_i to the Borel σ-algebra of X_i for each $i \in I$. Each μ_i' is still τ-additive and equidistributed sequences for μ_i are of course equidistributed for μ_i'. If we take λ' to be the τ-additive product of $\langle\mu_i'\rangle_{i\in I}$, then it must agree with λ on the open sets of X and therefore on the closed sets, and an equidistributed sequence for λ' will be an equidistributed sequence for λ. This completes the proof.

491G Corollary The usual measure of $\{0,1\}^{\mathfrak{c}}$ has an equidistributed sequence.

proof The usual measure of $\{0,1\}$ of course has an equidistributed sequence (just set $x_i = 0$ for even i, $x_i = 1$ for odd i), so 491F gives the result at once.

491H Theorem (VEECH 71) Any separable compact Hausdorff topological group has an equidistributed sequence for its Haar probability measure.

proof Let X be a separable compact Hausdorff topological group. Recall that X has exactly one Haar probability measure μ (442Ic), which is both a left Haar measure and a right Haar measure.

(a) We need some elementary facts about convolutions.

(i) If ν_1 and ν_2 are point-supported probability measures on X, then $\nu_1 * \nu_2$ is point-supported. **P** If $\nu_1 E = \sum_{x\in E} q_1(x)$ and $\nu_2 E = \sum_{x\in E} q_2(x)$ for every $E \subseteq X$, then

$$(\nu_1 * \nu_2)(E) = (\nu_1 \times \nu_2)\{(x,y) : xy \in E\} = \sum_{xy\in E} q_1(x)q_2(y) = \sum_{z\in E} q(z)$$

where $q(z) = \sum_{x\in X} q_1(x)q_2(x^{-1}z)$ for $z \in X$. **Q**

(ii) Let ν, λ be Radon probability measures on X. Suppose that $f \in C(X)$, $\alpha \in \mathbb{R}$ and $\epsilon > 0$ are such that $|\int f(yxz)\nu(dx) - \alpha| \leq \epsilon$ for every y, $z \in X$. Then $|\int f(yxz)(\lambda * \nu)(dx) - \alpha| \leq \epsilon$ and $|\int f(yxz)(\lambda * \nu)(dx) - \alpha| \leq \epsilon$ for every y, $z \in X$. **P**

$$\begin{aligned}
&|\int f(yxz)(\lambda * \nu)(dx) - \alpha| \\
&\qquad = |\iint f(ywxz)\nu(dx)\lambda(dw) - \alpha| \\
&\qquad \leq \int |\int f(ywxz)\nu(dx) - \alpha|\lambda(dw) \leq \int \epsilon\lambda(dw) = \epsilon, \qquad \text{(444C)} \\
&|\int f(yxz)(\nu * \lambda)(dx) - \alpha| \\
&\qquad = |\iint f(yxwz)\nu(dx)\lambda(dw) - \alpha| \\
&\qquad \leq \int |\int f(yxwz)\nu(dx) - \alpha|\lambda(dw) \leq \int \epsilon\lambda(dw) = \epsilon. \ \mathbf{Q}
\end{aligned}$$

(b) Let $A \subseteq X$ be a countable dense set. Let N be the set of point-supported probability measures ν on X which are defined by functions q such that $\{x : q(x) > 0\}$ is a finite subset of A and $q(x)$ is rational for every x. Then N is countable. Now, for every $f \in C(X)$ and $\epsilon > 0$, there is a $\nu \in$ N such that $|\int f(yxz)\nu(dx) - \int f d\mu| \leq \epsilon$ for all y, $z \in X$. **P** Because X is compact, f is uniformly continuous for the right uniformity of X (4A2Je), so there is a neighbourhood U of the identity e such that $|f(x') - f(x)| \leq \frac{1}{2}\epsilon$ whenever $x'x^{-1} \in U$. Next, again because X is compact, there is a neighbourhood V of e such that $yxy^{-1} \in U$ whenever $x \in V$ and $y \in X$ (4A5Ej). Because A is dense, $xV^{-1} \cap A \neq \emptyset$ is not empty for every $x \in X$, that is, $AV = X$; once more because X is compact, there are $x_0, \ldots, x_n \in A$ such that $X = \bigcup_{i\leq n} x_iV$. Set $E_i = x_iV \setminus \bigcup_{j<i} x_jV$ for each $i \leq n$. Let $\alpha_0, \ldots, \alpha_n \in [0,1] \cap \mathbb{Q}$ be such that $\sum_{i=0}^n \alpha_i = 1$ and $\|f\|_\infty \sum_{i=0}^n |\alpha_i - \mu E_i| \leq \frac{1}{2}\epsilon$, and define $\nu \in$ N by setting $\nu E = \sum\{\alpha_i : i \leq n, x_i \in E\}$ for every $E \subseteq X$.

Let y, $z \in X$. If $i \leq n$ and $x \in E_i$, then $xx_i^{-1} \in V$ so $(yxz)(yx_iz)^{-1} = yxx_i^{-1}y^{-1} \in U$ and $|f(yxz) - f(yx_iz)| \leq \frac{1}{2}\epsilon$. Accordingly

$$\begin{aligned}
&|\int f(yxz)\nu(dx) - \int f(x)\mu(dx)| \\
&\qquad = |\sum_{i=0}^n \alpha_i f(yx_iz) - \int f(yxz)\mu(dx)| \\
&\qquad \text{(because } X \text{ is unimodular)} \\
&\qquad \leq \sum_{i=0}^n |\alpha_i f(yx_iz) - \int_{E_i} f(yxz)\mu(dx)| \\
&\qquad \leq \sum_{i=0}^n |\alpha_i - \mu E_i||f(yx_iz)| + \sum_{i=0}^n |f(yx_iz)\mu E_i - \int_{E_i} f(yxz)\mu(dx)| \\
&\qquad \leq \|f\|_\infty \sum_{i=0}^n |\alpha_i - \mu E_i| + \sum_{i=0}^n \int_{E_i} |f(yxz) - f(yx_iz)|\mu(dx) \\
&\qquad \leq \frac{\epsilon}{2} + \sum_{i=0}^n \frac{\epsilon}{2}\mu E_i = \epsilon. \ \mathbf{Q}
\end{aligned}$$

(c) Let $\langle \nu_n \rangle_{n\in\mathbb{N}}$ be a sequence running over N, and set $\lambda_n = \nu_0 * \nu_1 * \ldots * \nu_n$ for each n. Then each λ_n is a point-supported probability measure on X, by (a)(i). Also $\lim_{n\to\infty} \int f d\lambda_n = \int f d\mu$ for every $f \in C(X)$. **P** If $f \in C(X)$ and $\epsilon > 0$, then (b) tells us that there is an $m \in \mathbb{N}$ such that $|\int f(yxz)\nu_m(dx) - \int f d\mu| \leq \epsilon$ for all y, $z \in X$. For any $n \geq m$, λ_n is of the form $\lambda' * \nu_m * \lambda''$. By (a)(ii), used in both parts successively, $|\int f d\lambda_n - \int f d\mu| \leq \epsilon$. As ϵ is arbitrary, we have the result. **Q**

(d) If $F \subseteq X$ is closed, then

$$\begin{aligned}\mu F &= \inf\{\int f d\mu : \chi F \leq f \in C(X)\} \\ &= \inf_{\chi F \leq f} \limsup_{n\to\infty} \int f d\lambda_n \geq \limsup_{n\to\infty} \lambda_n F.\end{aligned}$$

By 491D, μ has an equidistributed sequence.

491I The quotient $\mathcal{P}\mathbb{N}/\mathcal{Z}$ I now return to the asymptotic density ideal $\mathcal{Z}$, moving towards a striking relationship between the corresponding quotient algebra and equidistributed sequences. Since $\mathcal{Z} \lhd \mathcal{P}\mathbb{N}$, we can form the quotient algebra $\mathfrak{Z} = \mathcal{P}\mathbb{N}/\mathcal{Z}$. The functionals d and d^* descend naturally to $\mathfrak{Z}$ if we set

$$\bar{d}^*(I^\bullet) = d^*(I), \quad \bar{d}(I^\bullet) = d(I) \text{ whenever } d(I) \text{ is defined.}$$

(a) $\bar{d}^*$ is a strictly positive submeasure on $\mathfrak{Z}$. **P** $\bar{d}^*$ is a submeasure on $\mathfrak{Z}$ because d^* is a submeasure on $\mathcal{P}\mathbb{N}$. $\bar{d}^*$ is strictly positive because $\mathcal{Z} \supseteq \{I : d^*(I) = 0\}$. **Q**

(b) Let $\bar{\rho}$ be the metric on $\mathfrak{Z}$ defined by saying that $\bar{\rho}(a, b) = \bar{d}^*(a \triangle b)$ for all a, $b \in \mathfrak{Z}$. Under ρ, the Boolean operations $\cup$, $\cap$, $\triangle$ and $\setminus$ and the function $\bar{d}^* : \mathfrak{Z} \to [0, 1]$ are uniformly continuous (393Bb), and $\mathfrak{Z}$ is complete. **P** Let $\langle c_n \rangle_{n\in\mathbb{N}}$ be a sequence in $\mathfrak{Z}$ such that $\bar{\rho}(c_{n+1}, c_n) \leq 2^{-n}$ for every $n \in \mathbb{N}$; then $\bar{\rho}(c_r, c_i) \leq 2^{-i+1}$ for $i \leq r$. For each $n \in \mathbb{N}$ choose $C_n \subseteq \mathbb{N}$ such that $C_n^\bullet = c_n$; then $d^*(C_r \triangle C_i) \leq 2^{-i+1}$ for $i \leq r$. Choose a strictly increasing sequence $\langle k_n \rangle_{n\in\mathbb{N}}$ in $\mathbb{N}$ such that $k_{n+1} \geq 2k_n$ for every n and, for each $n \in \mathbb{N}$,

$$\frac{1}{m}\#((C_n \triangle C_i) \cap m) \leq 2^{-i+2} \text{ whenever } i \leq n,\ m \geq k_n.$$

Set $C = \bigcup_{n\in\mathbb{N}} C_n \cap k_{n+1} \setminus k_n$, and $c = C^\bullet \in \mathfrak{Z}$. If $n \in \mathbb{N}$ and $m \geq k_{n+1}$, then take $r > n$ such that $k_r \leq m < k_{r+1}$; in this case $k_i \leq 2^{i-r}m$ for $i \leq r$, so

$$\begin{aligned}\#((C \triangle C_n) \cap m) &\leq k_n + \sum_{i=n}^{r-1} \#((C \triangle C_n) \cap k_{i+1} \setminus k_i) + \#((C \triangle C_n) \cap m \setminus k_r) \\ &= k_n + \sum_{i=n}^{r-1} \#((C_i \triangle C_n) \cap k_{i+1} \setminus k_i) + \#((C_r \triangle C_n) \cap m \setminus k_r) \\ &\leq k_n + \sum_{i=n+1}^{r-1} \#((C_i \triangle C_n) \cap k_{i+1}) + \#((C_r \triangle C_n) \cap m) \\ &\leq k_n + \sum_{i=n+1}^{r-1} 2^{-n+2}k_{i+1} + 2^{-n+2}m \\ &\leq k_n + \sum_{i=n+1}^{r-1} 2^{-n+2}2^{i+1-r}m + 2^{-n+2}m \\ &\leq k_n + 2^{-n+3}m + 2^{-n+2}m.\end{aligned}$$

But this means that

$$\bar{\rho}(c, c_n) = d^*(C \triangle C_n) \leq \lim_{m\to\infty} \tfrac{k_n}{m} + 2^{-n+3} + 2^{-n+2} \leq 2^{-n+4}$$

for every n, and $\langle c_n \rangle_{n\in\mathbb{N}}$ converges to c in $\mathfrak{Z}$. **Q**

***(c)** If $\langle a_n\rangle_{n\in\mathbb{N}}$ is a non-increasing sequence in $\mathfrak{Z}$, there is an $a\in\mathfrak{Z}$ such that $a\subseteq a_n$ for every n and $\bar{d}^*(a)=\inf_{n\in\mathbb{N}}\bar{d}^*(a_n)$. **P** For each $n\in\mathbb{N}$, choose $I_n\subseteq\mathbb{N}$ such that $I_n^\bullet=a_n$; replacing I_n by $\bigcap_{j\le n}I_j$ if necessary, we can arrange that $I_{n+1}\subseteq I_n$ for every n. Set $\gamma=\inf_{n\in\mathbb{N}}\bar{d}^*(a_n)=\inf_{n\in\mathbb{N}}d^*(I_n)$. Let $\langle k_n\rangle_{n\in\mathbb{N}}$ be a strictly increasing sequence in $\mathbb{N}$ such that $k_{n+1}\ge 2^nk_n$ and $\#(I_n\cap k_{n+1})\ge(\gamma-2^{-n})k_{n+1}$ for every n. Set $K_n=I_n\cap k_{n+1}\setminus k_n$ for each n, and $I=\bigcup_{n\in\mathbb{N}}K_n$, $a=I^\bullet\in\mathfrak{Z}$. Then

$$\#(I\cap k_{n+1})\ge\#(K_n)\ge(\gamma-2^{-n+1})k_{n+1}$$

for each n, so $\bar{d}^*(a)=d^*(I)\ge\gamma$. Also $I\setminus I_n\subseteq k_n$ is finite, so $a\subseteq a_n$ for each n. Of course it follows at once that $\bar{d}^*(a)=\gamma$ exactly, as required. **Q**

***(d)** $\bar{d}^*$ is a Maharam submeasure on $\mathfrak{Z}$. (Immediate from (c).)

491J Lemma Let $\langle a_n\rangle_{n\in\mathbb{N}}$ be a non-decreasing sequence in $\mathfrak{Z}=\mathcal{P}\mathbb{N}/\mathcal{Z}$ such that $\lim_{n\to\infty}\bar{d}^*(a_n)+\bar{d}^*(1\setminus a_n)=1$. Then $\langle a_n\rangle_{n\in\mathbb{N}}$ is topologically convergent to $a\in\mathfrak{Z}$; $a=\sup_{n\in\mathbb{N}}a_n$ in $\mathfrak{Z}$ and $d^*(a)+d^*(1\setminus a)=1$.

proof (a) The point is that if $m\le n$ then $\bar{d}^*(a_n\setminus a_m)\le\bar{d}^*(a_n)+\bar{d}^*(1\setminus a_m)-1$. **P** Let I, $J\subseteq\mathbb{N}$ be such that $I^\bullet=a_m$ and $J^\bullet=a_n$. For any $k\ge1$,

$$\tfrac{1}{k}\#(k\cap J)+\tfrac{1}{k}\#(k\setminus I)=\tfrac{1}{k}\#(k\cap J\setminus I)+\tfrac{1}{k}(k\setminus(I\setminus J)),$$

so

$$\begin{aligned}d^*(J)+d^*(\mathbb{N}\setminus I)&=\limsup_{k\to\infty}\tfrac{1}{k}\#(k\cap J)+\limsup_{k\to\infty}\tfrac{1}{k}\#(k\setminus I)\\&\ge\limsup_{k\to\infty}\tfrac{1}{k}\#(k\cap J)+\tfrac{1}{k}\#(k\setminus I)\\&=\limsup_{k\to\infty}\tfrac{1}{k}\#(k\cap J\setminus I)+\tfrac{1}{k}(k\setminus(I\setminus J))\\&\ge\limsup_{k\to\infty}\tfrac{1}{k}\#(k\cap J\setminus I)+\liminf_{k\to\infty}\tfrac{1}{k}(k\setminus(I\setminus J))=d^*(J\setminus I)+1\end{aligned}$$

because $a_m\subseteq a_n$, so $I\setminus J\in\mathcal{Z}$. But this means that

$$\bar{d}^*(a_n\setminus a_m)=d^*(J\setminus I)\le d^*(J)+d^*(\mathbb{N}\setminus I)-1=\bar{d}^*(a_n)+\bar{d}^*(1\setminus a_m)-1.$$ **Q**

(b) Accordingly

$$\begin{aligned}\limsup_{m\to\infty}\sup_{n\ge m}\bar{\rho}(a_m,a_n)&=\limsup_{m\to\infty}\sup_{n\ge m}\bar{d}^*(a_n\setminus a_m)\\&\le\limsup_{m\to\infty}\sup_{n\ge m}\bar{d}^*(a_n)+\bar{d}^*(1\setminus a_m)-1\\&=\limsup_{m\to\infty}\sup_{n\ge m}\bar{d}^*(a_n)-\bar{d}^*(a_m)\end{aligned}$$

(because $\lim_{m\to\infty}\bar{d}^*(a_m)+\bar{d}^*(1\setminus a_m)=1$)

$$=0,$$

and $\langle a_n\rangle_{n\in\mathbb{N}}$ is a Cauchy sequence in $\mathfrak{Z}$.

(c) Because $\mathfrak{Z}$ is complete, $a=\lim_{n\to\infty}a_n$ is defined in $\mathfrak{Z}$. For each $m\in\mathbb{N}$, $a_m\setminus a=\lim_{n\to\infty}a_m\setminus a_n=0$ (because $\setminus$ is continuous), so $a_m\subseteq a$; thus a is an upper bound of $\{a_n:n\in\mathbb{N}\}$. If b is any upper bound of $\{a_n:n\in\mathbb{N}\}$, then $a\setminus b=\lim_{n\to\infty}a_n\setminus b=0$; so $a=\sup_{n\in\mathbb{N}}a_n$. Finally,

$$\bar{d}^*(a)+\bar{d}^*(1\setminus a)=\lim_{n\to\infty}\bar{d}^*(a_n)+\bar{d}^*(1\setminus a_n)=1.$$

491K Corollary Set $D = \{I^\bullet : I \subseteq \mathbb{N}, d(I) \text{ is defined}\} \subseteq \mathfrak{Z} = \mathcal{P}\mathbb{N}/\mathcal{Z}$.

(a) If $I \subseteq \mathbb{N}$ and $I^\bullet \in D$ then $d(I)$ is defined.

(b) $D = \{a : a \in \mathfrak{Z}, \bar{d}^*(a) + \bar{d}^*(1 \setminus a) = 1\}$; if $a \in D$ then $1 \setminus a \in D$; if a, $b \in D$ and $a \cap b = 0$, then $a \cup b \in D$ and $\bar{d}^*(a \cup b) = \bar{d}^*(a) + \bar{d}^*(b)$; if a, $b \in D$ and $a \subseteq b$ then $b \setminus a \in D$ and $\bar{d}^*(b \setminus a) = \bar{d}^*(b) - \bar{d}^*(a)$.

(c) D is a topologically closed subset of $\mathfrak{Z}$.

(d) If $A \subseteq D$ is upwards-directed, then $\sup A$ is defined in $\mathfrak{Z}$ and belongs to D; moreover there is a sequence in A with the same supremum as A, and $\sup A$ belongs to the topological closure of A.

(e) Let $\mathfrak{B} \subseteq D$ be a subalgebra of $\mathfrak{Z}$. Then the following are equiveridical:

(i) $\mathfrak{B}$ is topologically closed in $\mathfrak{Z}$;

(ii) $\mathfrak{B}$ is order-closed in $\mathfrak{Z}$;

(iii) setting $\bar{\nu} = \bar{d}^* \restriction \mathfrak{B}$, $(\mathfrak{B}, \bar{\nu})$ is a probability algebra.

In this case, $\mathfrak{B}$ is regularly embedded in $\mathfrak{Z}$.

(f) If $I \subseteq D$ is closed under either $\cap$ or $\cup$, then the topologically closed subalgebra of $\mathfrak{Z}$ generated by I, which is also the order-closed subalgebra of $\mathfrak{Z}$ generated by I, is included in D.

proof (a) There is a $J \subseteq \mathbb{N}$ such that $d(J)$ is defined and $I \triangle J \in \mathcal{Z}$. But in this case $d(I \triangle J) = 0$, so $d(I \cup J) = d(J) + d(I \setminus J)$ is defined; also $d(J \setminus I) = 0$, so $d(I) = d(I \cup J) - d(J \setminus I)$ is defined.

(b) These facts all follow directly from the corresponding results concerning $\mathcal{P}\mathbb{N}$ and d (491Ac).

(c) All we have to know is that $a \mapsto \bar{d}^*(a)$, $a \mapsto 1 \setminus a$ are continuous; so that $\{a : \bar{d}^*(a) + \bar{d}^*(1 \setminus a) = 1\}$ is closed.

(d) Because A is upwards-directed, and $\bar{d}^*$ is a non-decreasing functional on $\mathfrak{Z}$, there is a non-decreasing sequence $\langle a_n \rangle_{n \in \mathbb{N}}$ in A such that $\lim_{n \to \infty} \bar{d}^*(a_n) = \sup_{a \in A} \bar{d}^*(a) = \gamma$ say. By 491J, $b = \lim_{n \to \infty} a_n = \sup_{n \in \mathbb{N}} a_n$ is defined in $\mathfrak{Z}$ and belongs to D. If $a \in A$ and $\epsilon > 0$, there is an $n \in \mathbb{N}$ such that $\bar{d}^*(a_n) \geq \gamma - \epsilon$. Let $a' \in A$ be a common upper bound of a and a_n. Then

$$\bar{d}^*(a \setminus b) \leq \bar{d}^*(a' \setminus a_n) = \bar{d}^*(a') - \bar{d}^*(a_n) \leq \gamma - \bar{d}^*(a_n) \leq \epsilon.$$

As ϵ is arbitrary, $a \subseteq b$; as a is arbitrary, b is an upper bound of A; as $b = \sup_{n \in \mathbb{N}} a_n$, b must be the supremum of A.

(e)(i)⇒(ii) Suppose that $\mathfrak{B}$ is topologically closed. If $A \subseteq \mathfrak{B}$ is a non-empty upwards-directed subset with supremum $b \in \mathfrak{Z}$, then (d) tells us that $b \in \overline{A} \subseteq \mathfrak{B}$. It follows that $\mathfrak{B}$ is order-closed in $\mathfrak{Z}$ (313E).

(ii)⇒(iii) Suppose that $\mathfrak{B}$ is order-closed in $\mathfrak{Z}$. If $A \subseteq \mathfrak{B}$ is non-empty, then $A' = \{a_0 \cup \ldots \cup a_n : a_0, \ldots, a_n \in A\}$ is non-empty and upwards-directed, so has a supremum in $\mathfrak{Z}$, which must belong to $\mathfrak{B}$, and must be the least upper bound of A in $\mathfrak{B}$. Thus $\mathfrak{B}$ is Dedekind (σ-)complete. Now let $\langle a_n \rangle_{n \in \mathbb{N}}$ be a disjoint sequence in $\mathfrak{B}$ and set $b_n = \sup_{i \leq n} a_i$ for each n. Then $\langle b_n \rangle_{n \in \mathbb{N}}$ is a non-decreasing sequence in D so has a limit and supremum $b \in D$, and $b \in \mathfrak{B}$. Also $\bar{d}^*(b_n) = \sum_{i=0}^n \bar{d}^*(a_i)$ for each n (induce on n), so

$$\bar{\nu} b = \bar{d}^*(b) = \lim_{n \to \infty} \bar{d}^*(b_n) = \sum_{i=0}^\infty \bar{d}^*(a_i) = \sum_{i=0}^\infty \bar{\nu} a_i.$$

Since certainly $\bar{\nu} 0 = 0$, $\bar{\nu} 1 = 1$ and $\bar{\nu} b > 0$ whenever $b \in \mathfrak{B} \setminus \{0\}$, $(\mathfrak{B}, \bar{\nu})$ is a probability algebra.

(iii)⇒(i) Suppose that $(\mathfrak{B}, \bar{\nu})$ is a probability algebra. Then it is complete under its measure metric (323Gc), which agrees on $\mathfrak{B}$ with the metric $\bar{\rho}$ of $\mathfrak{Z}$; so $\mathfrak{B}$ must be topologically closed in $\mathfrak{Z}$.

We see also that $\mathfrak{B}$ is regularly embedded in $\mathfrak{Z}$. **P** (Compare 323H.) If $A \subseteq \mathfrak{B}$ is non-empty and downwards-directed and has infimum 0 in $\mathfrak{B}$, and $b \in \mathfrak{Z}$ is any lower bound of A in $\mathfrak{Z}$, then

$$\bar{d}^*(b) \leq \inf_{a \in A} \bar{d}^*(a) = \inf_{a \in A} \bar{\nu} a = 0$$

(321F), so $b = 0$. Thus $\inf A = 0$ in $\mathfrak{Z}$. As A is arbitrary, this is enough to show that the identity map from $\mathfrak{B}$ to $\mathfrak{Z}$ is order-continuous (313Lb), that is, that $\mathfrak{B}$ is regularly embedded in $\mathfrak{Z}$. **Q**

(f) Suppose that $I \subseteq D$ is closed under $\cap$. By 313Gc, D includes the order-closed subalgebra of $\mathfrak{Z}$ generated by I. If, on the other hand, I is closed under $\cup$, then $I' = \{1 \setminus a : a \in I\}$ is a subset of D closed under $\cap$, so the order-closed subalgebra generated by I, which is also the order-closed subalgebra generated by I', is again included in D.

491L Effectively regular measures The examples 491Xe and 491Yb show that the definition in 491B is drawn a little too wide for comfort, and allows some uninteresting pathologies. These do not arise in the measure spaces we care most about, and the following definitions provide a fire-break. Let (X, Σ, μ) be a measure space, and $\mathfrak{T}$ a topology on X.

(a) I will say that a measurable subset K of X of finite measure is **regularly enveloped** if for every $\epsilon > 0$ there are an open measurable set G and a closed measurable set F such that $K \subseteq G \subseteq F$ and $\mu(F \setminus K) \leq \epsilon$.

(b) Note that the family $\mathcal{K}$ of regularly enveloped measurable sets of finite measure is closed under finite unions and countable intersections. **P** (i) If K_1, $K_2 \in \mathcal{K}$ and $*$ is either $\cup$ or $\cap$, let $\epsilon > 0$. Take measurable open sets G_1, G_2 and measurable closed sets F_1, F_2 such that $K_i \subseteq G_i \subseteq F_i$ and $\mu(F_i \setminus K_i) \leq \frac{1}{2}\epsilon$ for both i. Then $G_1 * G_2$ is a measurable open set, $F_1 * F_2$ is a measurable closed set, $K_1 * K_2 \subseteq G_1 * G_2 \subseteq F_1 * F_2$ and $\mu((F_1 * F_2) \setminus (K_1 * K_2)) \leq \epsilon$. As ϵ is arbitrary, $K_1 * K_2 \in \mathcal{K}$. (ii) If $\langle K_n \rangle_{n \in \mathbb{N}}$ is a non-increasing sequence in $\mathcal{K}$ with intersection K and $\epsilon > 0$, let $n \in \mathbb{N}$ be such that $\mu K_n < \mu K + \epsilon$. Then we can find a measurable open set G and a measurable closed set F such that $K_n \subseteq G \subseteq F$ and $\mu F \leq \mu K + \epsilon$. As ϵ is arbitrary, $K \in \mathcal{K}$. Together with (i), this is enough to show that $\mathcal{K}$ is closed under countable intersections. **Q**

(c) Now I say that μ is **effectively regular** if it is inner regular with respect to the regularly enveloped sets of finite measure.

491M Examples (a) Any totally finite Radon measure is effectively regular. **P** Let $(X, \mathfrak{T}, \Sigma, \mu)$ be a totally finite Radon measure space. If $K \subseteq X$ is compact and $\epsilon > 0$, let $L \subseteq X \setminus K$ be a compact set such that $\mu L \geq 1 - \mu K + \epsilon$. Let G, H be disjoint open sets including K, L respectively (4A2F(h-i)). Then $K \subseteq G \subseteq X \setminus H$, G is open, $X \setminus H$ is closed, both G and $X \setminus H$ are measurable, and $\mu((X \setminus H) \setminus K) \leq \epsilon$. This shows that every compact set is regularly enveloped, and μ is effectively regular. **Q**

(b) Let $(X, \mathfrak{T}, \Sigma, \mu)$ be a quasi-Radon measure space such that $\mathfrak{T}$ is a regular topology. Then μ is effectively regular. **P** Let $E \in \Sigma$ and take $\gamma < \mu E$. Choose sequences $\langle E_n \rangle_{n \in \mathbb{N}}$ and $\langle G_n \rangle_{n \in \mathbb{N}}$ inductively, as follows. $E_0 \subseteq E$ is to be any measurable set such that $\gamma < \mu E_0 < \infty$. Given that $\mu E_n > \gamma$, let G be an open set of finite measure such that $\mu(E_n \cap G) > \gamma$ (414Ea), and $F \subseteq G \setminus E_n$ a closed set such that $\mu F \geq \mu(G \setminus E_n) - 2^{-n}$. Let $\mathcal{H}$ be the family of open sets H such that $\overline{H} \subseteq G \setminus F$. Then $\mathcal{H}$ is upwards-directed and covers E_n (because $\mathfrak{T}$ is regular), so there is a $G_n \in \mathcal{H}$ such that $\mu(E_n \cap G_n) > \gamma$ (414Ea again). Now $\mu(\overline{G}_n \setminus E_n) \leq 2^{-n}$. Set $E_{n+1} = E_n \cap G_n$, and continue.

At the end of the induction, set $K = \bigcap_{n \in \mathbb{N}} E_n$. For each n, $K \subseteq G_n \subseteq \overline{G}_n$ and

$$\lim_{n \to \infty} \mu(\overline{G}_n \setminus K) \leq \lim_{n \to \infty} 2^{-n} + \mu(E_n \setminus K) = 0,$$

so K is regularly enveloped. At the same time, $K \subseteq E$ and $\mu K \geq \gamma$. As E and γ are arbitrary, μ is effectively regular. **Q**

(c) Any totally finite Baire measure is effectively regular. **P** Let μ be a totally finite Baire measure on a topological space X. If $F \subseteq X$ is a zero set, let $f : X \to \mathbb{R}$ be a continuous function such that $F = f^{-1}[\{0\}]$. For each $n \in \mathbb{N}$, set $G_n = \{x : |f(x)| < 2^{-n}\}$, $F_n = \{x : |f(x)| \leq 2^{-n}\}$; then G_n is a measurable open set, F_n is a measurable closed set, $F \subseteq G_n \subseteq F_n$ for every n and $\lim_{n \to \infty} \mu F_n = \mu F$ (because μ is totally finite). This shows that every zero set is regularly enveloped; as μ is inner regular with respect to the zero sets (412D), μ is effectively regular. **Q**

(d) A totally finite completion regular topological measure is effectively regular. (As in (c), all zero sets are regularly enveloped.)

491N Theorem Let X be a topological space and μ an effectively regular probability measure on X, with measure algebra $(\mathfrak{A}, \bar{\mu})$. Suppose that $\langle x_n \rangle_{n \in \mathbb{N}}$ is an equidistributed sequence in X. Then we have a unique order-continuous Boolean homomorphism $\pi : \mathfrak{A} \to \mathfrak{Z} = \mathcal{P}\mathbb{N}/\mathcal{Z}$ such that $\pi G^\bullet \subseteq \{n : x_n \in G\}^\bullet$ for every measurable open set $G \subseteq X$, and $\bar{d}^*(\pi a) = \bar{\mu} a$ for every $a \in \mathfrak{A}$.

proof (a) Define $\theta : \mathcal{P}X \to \mathfrak{Z}$ by setting $\theta A = \{n : x_n \in A\}^\bullet$ for $A \subseteq X$; then θ is a Boolean homomorphism. If $F \subseteq X$ is closed and measurable, then $\bar{d}^*(\theta F) \leq \mu F$, because $\langle x_n \rangle_{n \in \mathbb{N}}$ is equidistributed. Write $\mathcal{K}$ for the family of regularly enveloped measurable sets.

If $K \in \mathcal{K}$, then $\pi_0 K = \inf\{\theta G : K \subseteq G \in \Sigma \cap \mathfrak{T}\}$ is defined in $\mathfrak{Z}$, $\bar{d}^*(\pi_0 K) = \mu K$ and $\pi_0 K \in D$ as defined in 491K. **P** For each $n \in \mathbb{N}$, let G_n, $F_n \in \Sigma$ be such that $K \subseteq G_n \subseteq F_n$, G_n is open, F_n is closed and $\mu(F_n \setminus K) \leq 2^{-n}$. Set $H_n = X \setminus \bigcap_{i \leq n} G_i$. Then

$$\begin{aligned}\bar{d}^*(\theta H_n) + \bar{d}^*(1 \setminus \theta H_n) &\leq \bar{d}^*(\theta H_n) + \bar{d}^*(\theta(\bigcap_{i \leq n} F_i)) \leq \mu H_n + \mu(\bigcap_{i \leq n} F_i) \\ &\leq \mu(X \setminus K) + \mu F_n \leq 1 + 2^{-n}.\end{aligned}$$

Also $\langle \theta H_n \rangle_{n \in \mathbb{N}}$ is a non-decreasing sequence in $\mathfrak{Z}$. By 491J, $a = \lim_{n \to \infty} \theta H_n = \sup_{n \in \mathbb{N}} \theta H_n$ is defined in $\mathfrak{Z}$ and belongs to D. Set

$$b = 1 \setminus a = \lim_{n \to \infty} 1 \setminus \theta H_n = \lim_{n \to \infty} \theta(\textstyle\bigcap_{i \leq n} G_i),$$

so that b also belongs to D. If $K \subseteq G \in \Sigma \cap \mathfrak{T}$, then

$$b \setminus \theta G = \lim_{n \to \infty} \theta(\textstyle\bigcap_{i \leq n} G_i) \setminus \theta G = \lim_{n \to \infty} \theta(\textstyle\bigcap_{i \leq n} G_i \setminus G),$$

and

$$\begin{aligned}\bar{d}^*(b \setminus \theta G) &= \lim_{n \to \infty} \bar{d}^*(\theta(\bigcap_{i \leq n} G_i \setminus G)) \\ &\leq \lim_{n \to \infty} \bar{d}^*(\theta(\bigcap_{i \leq n} F_i \setminus G)) \leq \lim_{n \to \infty} \mu(\bigcap_{i \leq n} F_i \setminus G) = 0.\end{aligned}$$

This shows that $b \subseteq \theta G$ whenever $K \subseteq G \in \Sigma \cap \mathfrak{T}$. On the other hand, any lower bound of $\{\theta G : K \subseteq G \in \Sigma \cap \mathfrak{T}\}$ is also a lower bound of $\{\theta(\bigcap_{i \leq n} G_i) : n \in \mathbb{N}\}$, so is included in b. Thus $b = \inf\{\theta G : K \subseteq G \in \Sigma \cap \mathfrak{T}\}$.

To compute $\bar{d}^*(b)$, observe first that $b \subseteq 1 \setminus \theta H_n \subseteq \theta F_n$ for every n, so

$$\bar{d}^*(b) \leq \inf_{n \in \mathbb{N}} \bar{d}^*(\theta F_n) \leq \inf_{n \in \mathbb{N}} \mu F_n = \mu K.$$

On the other hand,

$$\bar{d}^*(\theta(\textstyle\bigcap_{i \leq n} G_i)) \geq 1 - \bar{d}^*(\theta H_n) \geq 1 - \mu H_n \geq \mu K$$

for every n, so

$$\bar{d}^*(b) = \lim_{n \to \infty} \bar{d}^*(\theta(\textstyle\bigcap_{i \leq n} G_i)) \geq \mu K.$$

Accordingly $\bar{d}^*(b) = \mu K$, and we can take b for $\pi_0 K$. **Q**

(b) If K, $L \in \mathcal{K}$, then $\pi_0(K \cap L) = \pi_0 K \cap \pi_0 L$. **P** We know that $K \cap L \in \mathcal{K}$ (491Lb). Now

$$\begin{aligned}\pi_0 K \cap \pi_0 L &= \inf\{\theta G : K \subseteq G \in \mathfrak{T}\} \cap \inf\{\theta H : L \subseteq H \in \mathfrak{T}\} \\ &= \inf\{\theta G \cap \theta H : K \subseteq G \in \mathfrak{T},\ L \subseteq H \in \mathfrak{T}\} \\ &= \inf\{\theta(G \cap H) : K \subseteq G \in \mathfrak{T},\ L \subseteq H \in \mathfrak{T}\} \supseteq \pi_0(K \cap L).\end{aligned}$$

Now suppose that $U \supseteq K \cap L$ is a measurable open set and $\epsilon > 0$. Let G, G' be measurable open sets and F, F' measurable closed sets such that $K \subseteq G \subseteq F$, $L \subseteq G' \subseteq F'$, $\mu(F \setminus K) \leq \epsilon$ and $\mu(F' \setminus L) \leq \epsilon$. Then

$$\begin{aligned}\bar{d}^*(\pi_0 K \cap \pi_0 L \setminus \theta U) &\leq \bar{d}^*(\theta G \cap \theta G' \setminus \theta U) = \bar{d}^*(\theta(G \cap G' \setminus U)) \\ &\leq \bar{d}^*(\theta(F \cap F' \setminus U)) \leq \mu(F \cap F' \setminus U) \leq 2\epsilon.\end{aligned}$$

As ϵ is arbitrary, $\pi_0 K \cap \pi_0 L \subseteq \theta U$; as U is arbitrary, $\pi_0 K \cap \pi_0 L \subseteq \pi_0(K \cap L)$. **Q**

This means that $\{\pi_0 K : K \subseteq X \text{ is a regularly embedded measurable set}\}$ is a subset of D closed under $\cap$. By 491Kf, the topologically closed subalgebra $\mathfrak{B}$ of $\mathfrak{Z}$ generated by this family is included in D; by 491Ke, $\mathfrak{B}$ is order-closed and regularly embedded in $\mathfrak{Z}$, and $(\mathfrak{B}, \bar{d}^* \restriction \mathfrak{B})$ is a probability algebra.

(c) Now observe that if we set $Q = \{K^\bullet : K \in \mathcal{K}\} \subseteq \mathfrak{A}$, we have a function $\pi : Q \to \mathfrak{B}$ defined by setting $\pi K^\bullet = \pi_0 K$ whenever $K \in \mathcal{K}$. **P** Suppose that K, $L \in \mathcal{K}$ are compact and $\mu(K \triangle L) = 0$. Then

$$\bar{d}^*(\pi_0 K \triangle \pi_0 L) = \bar{d}^*(\pi_0 K) + \bar{d}^*(\pi_0 L) - 2\bar{d}^*(\pi_0 K \cap \pi_0 L)$$

(because $\pi_0 K$ and $\pi_0 L$ belong to $\mathfrak{B} \subseteq D$)

$$= \bar{d}^*(\pi_0 K) + \bar{d}^*(\pi_0 L) - 2\bar{d}^*(\pi_0(K \cap L))$$
$$= \mu K + \mu L - 2\mu(K \cap L) = 0.$$

So $\pi_0 K = \pi_0 L$ and either can be used to define $\pi K^\bullet$. **Q** Next, the same formulae show that $\pi : Q \to \mathfrak{B}$ is an isometry when Q is given the measure metric of $\mathfrak{A}$, since if K, $L \subseteq X$ are compact

$$\bar{\rho}(\pi K^\bullet, \pi L^\bullet) = \bar{d}^*(\pi_0 K \triangle \pi_0 L) = \mu K + \mu L - 2\mu(K \cap L) = \mu(K \triangle L) = \bar{\mu}(K^\bullet \triangle L^\bullet).$$

As Q is dense in $\mathfrak{A}$ (412N), there is a unique extension of π to an isometry from $\mathfrak{A}$ to $\mathfrak{B}$.

(d) Because

$$\pi(K^\bullet \cap L^\bullet) = \pi(K \cap L)^\bullet = \pi_0(K \cap L) = \pi_0 K \cap \pi_0 L = \pi K^\bullet \cap \pi L^\bullet$$

for all K, $L \in \mathcal{K}$, $\pi(a \cap a') = \pi a \cap \pi a'$ for all a, $a' \in \mathfrak{A}$. It follows that π is a Boolean homomorphism. **P** The point is that $\bar{d}^*(\pi a) = \bar{\mu} a$ for every $a \in Q$, and therefore for every $a \in \mathfrak{A}$. Now if $a \in \mathfrak{A}$, $\pi(1 \setminus a)$ must be disjoint from πa (since certainly $\pi 0 = 0$), and has the same measure as $1 \setminus \pi a$ (remember that we know that $(\mathfrak{B}, \bar{d}^* \restriction \mathfrak{B})$ is a measure algebra), so must be equal to $1 \setminus \pi a$. By 312H, π is a Boolean homomorphism. **Q**

By 324G, π is order-continuous when regarded as a function from $\mathfrak{A}$ to $\mathfrak{B}$. Because $\mathfrak{B}$ is regularly embedded in $\mathfrak{Z}$, π is order-continuous when regarded as a function from $\mathfrak{A}$ to $\mathfrak{Z}$.

(e) Let $G \in \Sigma \cap \mathfrak{T}$. For any $\epsilon > 0$, there is a $K \in \mathcal{K}$ such that $K \subseteq G$ and $\mu(G \setminus K) \leq \epsilon$. In this case, $\pi K^\bullet = \pi_0 K \subseteq \theta G$. So

$$\bar{d}^*(\pi G^\bullet \setminus \theta G) \leq \bar{d}^*(\pi G^\bullet \setminus \pi K^\bullet) = \bar{\mu}(G^\bullet \setminus K^\bullet) = \mu(G \setminus K) \leq \epsilon.$$

As ϵ is arbitrary, $\pi G^\bullet \subseteq \theta G$.

(f) This shows that we have a homomorphism π with the required properties. To see that π is unique, suppose that $\pi' : \mathfrak{A} \to \mathfrak{Z}$ is any homomorphism of the same kind. In this case

$$\bar{d}^*(1 \setminus \pi' a) = \bar{d}^*(\pi'(1 \setminus a)) = \bar{\mu}(1 \setminus a) = 1 - \bar{\mu} a = 1 - \bar{d}^*(\pi' a),$$

so $\pi' a \in D$, for every $a \in \mathfrak{A}$. If $K \in \mathcal{K}$, then $\pi' K^\bullet \subseteq \theta G$ whenever $K \subseteq G \in \Sigma \cap \mathfrak{T}$, so $\pi' K^\bullet \subseteq \pi_0 K = \pi K^\bullet$. As both $\pi K^\bullet$ and $\pi' K^\bullet$ belong to D,

$$\bar{d}^*(\pi K^\bullet \setminus \pi' K^\bullet) = \bar{d}^*(\pi K^\bullet) - \bar{d}^*(\pi' K^\bullet) = \mu K - \mu K = 0,$$

and $\pi K^\bullet = \pi' K^\bullet$. As $\{K^\bullet : K \in \mathcal{K}\}$ is topologically dense in $\mathfrak{A}$, and both π and π' are continuous, they must be equal.

491O Proposition Let X be a topological space and μ an effectively regular probability measure on X which measures every zero set, and suppose that $\langle x_n \rangle_{n \in \mathbb{N}}$ is an equidistributed sequence in X. Let $\mathfrak{A}$ be the measure algebra of μ and $\pi : \mathfrak{A} \to \mathfrak{Z} = \mathcal{P}\mathbb{N}/\mathcal{Z}$ the regular embedding described in 491N; let $T_\pi : L^\infty(\mathfrak{A}) \to L^\infty(\mathfrak{Z})$ be the corresponding order-continuous Banach algebra embedding (363F). Let $S : \ell^\infty(X) \to \ell^\infty$ be the Riesz homomorphism defined by setting $(Sf)(n) = f(x_n)$ for $f \in \ell^\infty(X)$ and $n \in \mathbb{N}$, and $R : \ell^\infty \to L^\infty(\mathfrak{Z})$ the Riesz homomorphism corresponding to the Boolean homomorphism $I \mapsto I^\bullet : \mathcal{P}\mathbb{N} \to \mathfrak{Z}$. For $f \in \mathfrak{L}^\infty(\mu)$ let $f^\bullet$ be the corresponding member of $L^\infty(\mu) \cong L^\infty(\mathfrak{A})$ (363I). Then $T_\pi(f^\bullet) = RSf$ for every $f \in C_b(X)$.

proof To begin with, suppose that $f : X \to [0,1]$ is continuous and $k \geq 1$. For each $i \leq k$ set $G_i = \{x : f(x) > \frac{i}{k}\}$, $F_i = \{x : f(x) \geq \frac{i}{k}\}$. Then $\frac{1}{k}\sum_{i=1}^k \chi F_i \leq f \leq \frac{1}{k}\sum_{i=0}^k \chi G_i$. So

$$\frac{1}{k}\sum_{i=1}^k \chi(\pi F_i^\bullet) \leq T_\pi f^\bullet \leq \frac{1}{k}\sum_{i=0}^k \chi(\pi G_i^\bullet),$$

$$\frac{1}{k}\sum_{i=1}^k \chi(\theta F_i) \leq RSf \leq \frac{1}{k}\sum_{i=0}^k \chi(\theta G_i)$$

where $\theta : \mathcal{P}X \to \mathfrak{Z}$ is the Boolean homomorphism described in 491N, because $RS : \ell^\infty \to L^\infty(\mathfrak{Z})$ is the Riesz homomorphism corresponding to θ (see 363Fa, 363Fg). Now 491N tells us that $\pi G^\bullet \subseteq \theta G$ for every open $G \subseteq X$, so

$$\begin{aligned} T_\pi f^\bullet &\leq \frac{1}{k}\sum_{i=0}^{k} \chi(\pi G_i^\bullet) \leq \frac{1}{k}\sum_{i=0}^{k} \chi(\theta G_i) \\ &\leq \frac{1}{k}\sum_{i=0}^{k} \chi(\theta F_i) = \frac{1}{k}e + \sum_{i=1}^{k} \chi(\theta F_i) \leq \frac{1}{k}e + RSf \end{aligned}$$

where e is the standard order unit of the M-space $L^\infty(\mathfrak{Z})$. But looking at complements we see that we must have $\pi F^\bullet \supseteq \theta F$ for every closed set $F \subseteq X$, so

$$\begin{aligned} RSf &\leq \frac{1}{k}\sum_{i=0}^{k} \chi(\theta G_i) \leq \frac{1}{k}\sum_{i=0}^{k} \chi(\theta F_i) \\ &\leq \frac{1}{k}\sum_{i=0}^{k} \chi(\pi F_i^\bullet) = \frac{1}{k}e + \sum_{i=1}^{k} \chi(\pi F_i^\bullet) \leq \frac{1}{k}e + T_\pi f^\bullet. \end{aligned}$$

This means that $|T_\pi f^\bullet - RSf| \leq \frac{1}{k}e$ for every $k \geq 1$, so that $T_\pi f^\bullet = RSf$. This is true whenever $f \in C_b(X)$ takes values in $[0,1]$; as all the operators here are linear, it is true for every $f \in C_b(X)$.

491P Proposition Any probability algebra $(\mathfrak{A}, \bar\mu)$ of cardinal at most $\mathfrak{c}$ can be regularly embedded as a subalgebra of $\mathfrak{Z} = \mathcal{P}\mathbb{N}/\mathcal{Z}$ in such a way that $\bar\mu$ is identified with the restriction of the submeasure $\bar d^*$ to the image of $\mathfrak{A}$.

proof The usual measure of $\{0,1\}^{\mathfrak{c}}$ is a totally finite Radon measure, so is effectively regular (491Ma). It has an equidistributed sequence (491G), so its measure algebra $(\mathfrak{B}_{\mathfrak{c}}, \bar\nu_{\mathfrak{c}})$ can be regularly embedded in $\mathfrak{Z}$ in a way which matches $\bar\nu_{\mathfrak{c}}$ with $\bar d^*$ (491N). Now if $(\mathfrak{A}, \bar\mu)$ is any probability algebra of cardinal at most $\mathfrak{c}$, it can be regularly embedded (by a measure-preserving homomorphism) in $(\mathfrak{B}_{\mathfrak{c}}, \bar\nu_{\mathfrak{c}})$ (332N), and therefore in $(\mathfrak{Z}, \bar d^*)$. This completes the proof.

491Q Corollary Every Radon probability measure on $\{0,1\}^{\mathfrak{c}}$ has an equidistributed sequence.

proof Let μ be a Radon probability measure on $\{0,1\}^{\mathfrak{c}}$, and $(\mathfrak{A}, \bar\mu)$ its measure algebra. By 491P, there is a measure-preserving embedding $\pi : \mathfrak{A} \to \mathfrak{Z}$, and $\pi[\mathfrak{A}] \subseteq D$ as defined in 491K. For $\xi < \mathfrak{c}$ let $a_\xi \in \mathfrak{A}$ be the equivalence class of $\{x : x(\xi) = 1\}$, and let $I_\xi \subseteq \mathbb{N}$ be such that $I_\xi^\bullet = \pi a_\xi$ in $\mathfrak{Z}$. Define $x_n(\xi)$, for $n \in \mathbb{N}$ and $\xi < \mathfrak{c}$, by setting $x_n(\xi) = 1$ if $n \in I_\xi$, 0 otherwise. Now suppose that $E \subseteq \{0,1\}^{\mathfrak{c}}$ is a basic open set of the form $\{x : x(\xi) = 1 \text{ for } \xi \in K,\ 0 \text{ for } \xi \in L\}$, where K, $L \subseteq \mathfrak{c}$ are finite. Set $b = \pi E^\bullet$ in $\mathfrak{Z}$,

$$I = \{n : x_n \in E\} = \mathbb{N} \cap \textstyle\bigcap_{\xi\in K} I_\xi \setminus \bigcup_{\xi\in L} I_\xi.$$

Then

$$\begin{aligned} b = \pi E^\bullet &= \pi(\inf_{\xi\in K} a_\xi \setminus \sup_{\xi\in L} a_\xi) \\ &= \inf_{\xi\in K} \pi a_\xi \setminus \sup_{\xi\in L} \pi a_\xi = \inf_{\xi\in K} I_\xi^\bullet \setminus \sup_{\xi\in L} I_\xi^\bullet = I^\bullet. \end{aligned}$$

Since $b \in D$, $d(I)$ is defined and is equal to $\bar d^*(b) = \bar\mu E^\bullet = \mu E$.

If we now take E to be an open-and-closed subset of $\{0,1\}^{\mathfrak{c}}$, it can be expressed as a disjoint union of finitely many basic open sets of the type just considered; because d is additive on disjoint sets, $d(\{n : x_n \in E\})$ is defined and equal to μE. But this is enough to ensure that $\langle x_n\rangle_{n\in\mathbb{N}}$ is equidistributed, by 491Ch.

491X Basic exercises (a) (i) Show that if I, $J \in \mathcal{D} = \operatorname{dom} d$ as defined in 491A, then $I \cup J \in \mathcal{D}$ iff $I \cap J \in \mathcal{D}$ iff $I \setminus J \in \mathcal{D}$ iff $I \triangle J \in \mathcal{D}$. (ii) Show that if $\mathcal{E} \subseteq \mathcal{D}$ is an algebra of sets, then $d\restriction\mathcal{E}$ is additive. (iii) Find I, $J \in \mathcal{D}$ such that $I \cap J \notin \mathcal{D}$.

>(b) Suppose that $I \subseteq \mathbb{N}$ and that $f : \mathbb{N} \to \mathbb{N}$ is strictly increasing. Show that $d^*(f[I]) \leq d^*(I)d^*(f[\mathbb{N}])$, with equality if either I or $f[\mathbb{N}]$ has asymptotic density.

(c) Show that if $A \subseteq \mathbb{N}$ and $0 \leq \alpha \leq d^*(A)$ there is a $B \subseteq A$ such that $d^*(B) = \alpha$ and $d^*(A \setminus B) = d^*(A) - \alpha$.

(d) (i) Let $I \subseteq \mathbb{N}$ be such that $d(J) = d^*(J \cap I) + d^*(J \setminus I)$ for every $J \subseteq \mathbb{N}$ such that $d(J)$ is defined. Show that either $I \in \mathcal{Z}$ or $\mathbb{N} \setminus I \mathcal{Z}$. (ii) Show that for every $\epsilon > 0$ there is an $I \subseteq \mathbb{N}$ such that $d^*(I) = \epsilon$ but $d(J) = 1$ whenever $J \supseteq I$ and $d(J)$ is defined.

(e) Let $(X, \mathfrak{T}, \Sigma, \mu)$ be a compact Radon probability space. Take any point ∞ not belonging to X, and give $X \cup \{\infty\}$ the topology generated by $\{G \cup \{\infty\} : G \in \mathfrak{T}\}$. Show that $X \cup \{\infty\}$ is compact and that the image measure μ_∞ of μ under the identity map from X to $X \cup \{\infty\}$ is a quasi-Radon measure, inner regular with respect to the compact sets. Show that if we set $x_n = \infty$ for every n, then $\langle x_n \rangle_{n \in \mathbb{N}}$ is equidistributed for μ_∞.

>(f) (i) Show that a sequence $\langle t_n \rangle_{n \in \mathbb{N}}$ in $[0,1]$ is equidistributed with respect to Lebesgue measure iff $\lim_{n \to \infty} \frac{1}{n+1} \#(\{i : i \leq n, t_i \leq \beta\}) = \beta$ for every $\beta \in [0,1]$. (ii) Show that if $\alpha \in \mathbb{R}$ is irrational then the sequence $\langle <n\alpha> \rangle_{n \in \mathbb{N}}$ of fractional parts of multiples of α is equidistributed in $[0,1]$ with respect to Lebesgue measure. (*Hint*: 281Yi.)

(g) Show that the usual measure on the split interval (419L) has an equidistributed sequence.

>(h) Show that if X is a regular Hausdorff space and $f : \mathbb{N} \to X$ is injective, then there is an open set $G \subseteq X$ such that $f^{-1}[G]$ does not have asymptotic density.

>(i) Let Z, μ, $X = Z \times \{0,1\}$ and ν be as described in 439K, so that μ is a Radon probability measure on the compact metrizable space Z, X has a compact Hausdorff topology finer than the product topology, and ν is a measure on Z extending μ. (i) Show that if $f \in C(X)$, then $\{t : t \in Z, f(t,0) \neq f(t,1)\}$ is countable. (*Hint*: 4A2F(h-vii).) (ii) Show that $\int f(t,0)\mu(dt) = \int f(t,1)\nu(dt)$ for every $f \in C(X)$. (iii) Let λ be the measure νg^{-1}, where $g(t) = (t,1)$ for $t \in Z$. Show that there is a sequence $\langle x_n \rangle_{n \in \mathbb{N}}$ in $Z \times \{0\}$ such that $\int f d\lambda = \lim_{n \to \infty} \frac{1}{n+1} \sum_{i=0}^{n} f(x_i)$ for every $f \in C(X)$, but that $\langle x_n \rangle_{n \in \mathbb{N}}$ is not λ-equidistributed.

(j) Show that a function $f : [0,1] \to \mathbb{R}$ is Riemann integrable iff $\lim_{n \to \infty} \frac{1}{n+1} \sum_{i=0}^{n} f(x_i)$ is defined in $\mathbb{R}$ for every sequence $\langle x_n \rangle_{n \in \mathbb{N}}$ in $[0,1]$ which is equidistributed for Lebesgue measure.

(k) Let X be a metrizable space, and μ a quasi-Radon probability measure on X. (i) Show that there is an equidistributed sequence for μ. (ii) Show that if the support of μ is not compact, and $\langle x_n \rangle_{n \in \mathbb{N}}$ is an equidistributed sequence for μ, then there is a continuous integrable function $f : X \to \mathbb{R}$ such that $\lim_{n \to \infty} \frac{1}{n+1} \sum_{i=0}^{n} f(x_i) = \infty$.

(l) Let $\phi : \mathfrak{c} \to \mathcal{P}\mathbb{N}$ be an injective function. For each $n \in \mathbb{N}$ let λ_n be the uniform measure on $\mathcal{P}(\mathcal{P}n)$, giving measure 2^{-2^n} to each point. Define $\psi_n : \mathcal{P}(\mathcal{P}n) \to \{0,1\}^{\mathfrak{c}}$ by setting $\psi_n(\mathcal{I})(\xi) = 1$ if $\phi(\xi) \cap n \in \mathcal{I}$, 0 otherwise, and let ν_n be the image measure $\lambda_n \psi_n^{-1}$. Show that $\nu_n E$ is the usual measure of E whenever $E \subseteq \{0,1\}^{\mathfrak{c}}$ is determined by coordinates in a finite set on which the map $\xi \mapsto \phi(\xi) \cap n$ is injective. Use this with 491D to prove 491G.

>(m) (i) Let Z be the Stone space of the measure algebra of Lebesgue measure on $[0,1]$, with its usual measure. Show that there is no equidistributed sequence in Z. (*Hint*: meager sets in Z have negligible closures.) (ii) Show that Dieudonné's measure on ω_1 (411Q) has no equidistributed sequence. (iii) Show that if $\#(I) > \mathfrak{c}$ then the usual measure on $\{0,1\}^I$ has no equidistributed sequence. (*Hint*: if $\langle x_n \rangle_{n \in \mathbb{N}}$ is any sequence in $\{0,1\}^I$, there is an infinite $J \subseteq I$ such that $\langle x_n(\eta) \rangle_{n \in \mathbb{N}} = \langle x_n(\xi) \rangle_{n \in \mathbb{N}}$ for all $\eta, \xi \in J$.) (iv) Show that if X is a topological group with a Haar probability measure μ, and X is not separable, then μ has no equidistributed sequence. (*Hint*: use 443D to show that every separable subset is negligible.)

(n) Let X be a compact Hausdorff abelian topological group and μ its Haar probability measure. Show that a sequence $\langle x_n\rangle_{n\in\mathbb{N}}$ in X is equidistributed for μ iff $\lim_{n\to\infty}\frac{1}{n+1}\sum_{i=0}^{n}\chi(x_i)=0$ for every non-trivial character $\chi: X\to S^1$. (*Hint*: 281G.)

(o) Show that $\mathfrak{Z}$ is not Dedekind σ-complete. (*Hint*: 392Hc.)

(p) Let $\langle a_n\rangle_{n\in\mathbb{N}}$ be a non-decreasing sequence in $\mathfrak{Z}$. Show that there is an $a\in\mathfrak{Z}$ such that $a_n\subseteq a$ for every $n\in\mathbb{N}$ and $\bar{d}^*(a)=\sup_{n\in\mathbb{N}}\bar{d}^*(a_n)$.

(q) Let $\mathfrak{Z}$, $\bar{d}^*$ and D be as in 491K. Show that if $a\in D\setminus\{0\}$ and $\mathfrak{Z}_a$ is the principal ideal of $\mathfrak{Z}$ generated by a, then $(\mathfrak{Z}_a,\bar{d}^*\restriction\mathfrak{Z}_a)$ is isomorphic, up to a scalar multiple of the submeasure, to $(\mathfrak{Z},\bar{d}^*)$.

(r) Let (X,Σ,μ) be a semi-finite measure space and $\mathfrak{T}$ a topology on X. Show that μ is effectively regular iff whenever $E\in\Sigma$, $\mu E<\infty$ and $\epsilon>0$ there are a measurable open set G and a measurable closed set $F\supseteq G$ such that $\mu(F\setminus E)+\mu(E\setminus G)\leq\epsilon$.

(s) Let X be a normal topological space and μ a topological measure on X which is inner regular with respect to the closed sets and effectively locally finite. Show that μ is effectively regular.

(t) Let X be a topological space and μ an effectively regular measure on X. (i) Show that the completion and c.l.d. version of μ are also effectively regular. (ii) Show that if $Y\subseteq X$ then the subspace measure is again effectively regular. (iii) Show that any totally finite indefinite-integral measure over μ is effectively regular.

(u) (i) Let X_1, X_2 be topological spaces with effectively regular measures μ_1, μ_2. Show that the c.l.d. product measure on $X_1\times X_2$ is effectively regular with respect to the product topology. (*Hint*: 412R.) (ii) Let $\langle X_i\rangle_{i\in I}$ be a family of topological spaces and μ_i an effectively regular probability measure on X_i for each i. Show that the product probability measure on $\prod_{i\in I}X_i$ is effectively regular.

(v) Give $[0,1]$ the topology $\mathfrak{T}$ generated by the usual topology and $\{[0,1]\setminus A: A\subseteq\mathbb{Q}\}$. Let μ_L be Lebesgue measure on $[0,1]$, and Σ its domain. For $E\in\Sigma$ set $\mu E=\mu_L E+\#(E\cap\mathbb{Q})$ if $E\cap\mathbb{Q}$ is finite, ∞ otherwise. Show that μ is a σ-finite quasi-Radon measure with respect to the topology $\mathfrak{T}$, but is not effectively regular.

(w) Let (X,ρ) be a separable metric space and μ a Borel probability measure on X. (i) Show that there is an equidistributed sequence in X. (ii) Show that if $\langle x_n\rangle_{n\in\mathbb{N}}$ is an equidistributed sequence in X, and $\langle y_n\rangle_{n\in\mathbb{N}}$ is a sequence in X such that $\lim_{n\to\infty}\rho(x_n,y_n)=0$, then $\langle y_n\rangle_{n\in\mathbb{N}}$ is equidistributed. (iii) Show that if $f: X\to\mathbb{R}$ is a bounded function, then $\lim_{n\to\infty}\frac{1}{n+1}\sum_{i=0}^{n}f(x_i)-f(y_i)=0$ for all equidistributed sequences $\langle x_n\rangle_{n\in\mathbb{N}}$, $\langle y_n\rangle_{n\in\mathbb{N}}$ in X iff $\{x: f$ is continuous at $x\}$ is conegligible, and in this case $\lim_{n\to\infty}\frac{1}{n+1}\sum_{i=0}^{n}f(x_i)=\int f d\mu$ for every equidistributed sequence $\langle x_n\rangle_{n\in\mathbb{N}}$ in X. (*Hint*: $\{x: f$ is continuous at $x\}=\bigcap_{m\in\mathbb{N}}G_m$, where $G_m=\bigcup\{G: G\subseteq X$ is open, $\sup_{x,y\in G}|f(x)-f(y)|\leq 2^{-m}\}$.) Compare 134L.

(x) Let $(X,\mathfrak{T})$ be a topological space, μ a probability measure on X, and $\phi: X\to X$ an inverse-measure-preserving function. (i) Suppose that $\mathfrak{T}$ has a countable network consisting of measurable sets, and that ϕ is ergodic. Show that $\langle\phi^n(x)\rangle_{n\in\mathbb{N}}$ is equidistributed for almost every $x\in X$. (*Hint*: 372Qb.) (ii) Suppose that μ is *either* inner regular with respect to the closed sets *or* effectively regular, and that $\{x:\langle\phi^n(x)\rangle_{n\in\mathbb{N}}$ is equidistributed$\}$ is not negligible. Show that ϕ is ergodic.

(y) Let $\mathfrak{A}$ be a countable Boolean algebra and ν a finitely additive functional on $\mathfrak{A}$ such that $\nu 1=1$. Show that there is a Boolean homomorphism $\pi:\mathfrak{A}\to\mathcal{P}\mathbb{N}$ such that $d(\pi a)$ is defined and equal to νa for every $a\in\mathfrak{A}$ (i) from 491Xc (ii) from 393B, 491P and 341Xf.

(z) Let X be a dyadic space. (i) Show that there is a Radon probability measure on X with support X. (ii) Show that the following are equiveridical: (α) $w(X)\leq\mathfrak{c}$; (β) every Radon probability measure on X has an equidistributed sequence; (γ) X is separable. (*Hint*: 4A2Dd, 418L.)

491Y Further exercises (a) Show that every subset A of $\mathbb{N}$ is expressible in the form $I_A \triangle J_A$ where $d(I_A) = d(J_A) = \frac{1}{2}$ (i) by a direct construction, with $A \mapsto I_A$ a continuous function (ii) using 443D.

(b) Find a topological space X with a τ-additive probability measure μ on X, a sequence $\langle x_n \rangle_{n\in\mathbb{N}}$ in X and a base $\mathcal{G}$ for the topology of X, consisting of measurable sets and closed under finite intersections, such that $\mu G \leq \liminf_{n\to\infty} \frac{1}{n+1}\#(\{i : i \leq n, x_i \in G\})$ for every $G \in \mathcal{G}$ but $\langle x_n \rangle_{n\in\mathbb{N}}$ is not equidistributed. (*Hint*: take $\#(X) = 4$.)

(c) Let X be a compact Hausdorff space on which every Radon probability measure has an equidistributed sequence. Show that the cylindrical σ-algebra of $C(X)$ is the σ-algebra generated by sets of the form $\{f : f \in C(X), f(x) > \alpha\}$ where $x \in X$ and $\alpha \in \mathbb{R}$. (*Hint*: 436J, 491Cb.)

(d) Give ω_1+1 and $[0,1]$ their usual compact Hausdorff topologies. Let $\langle t_i \rangle_{i\in\mathbb{N}}$ be a sequence in $[0,1]$ which is equidistributed for Lebesgue measure μ_L, and set $Q = \{t_i : i \in \mathbb{N}\}$, $X = (\omega_1 \times ([0,1] \setminus Q)) \cup (\{\omega_1\} \times Q)$, with the subspace topology inherited from $(\omega_1 + 1) \times [0,1]$. (i) Set $F = \{\omega_1\} \times Q$. Show that F is a closed Baire set in the completely regular Hausdorff space X. (ii) Show that if $f \in C_b(X)$ then there are a $g_f \in C([0,1])$ and a $\zeta < \omega_1$ such that such that $f(\xi, t) = g_f(t)$ whenever $(\xi, t) \in X$ and $\zeta \leq \xi \leq \omega_1$. (iii) Show that there is a Baire measure μ on X such that $\int f d\mu = \int g_f d\mu_L$ for every $f \in C_b(X)$. (iv) Show that $\mu F = 0$. (v) Show that $\int f d\mu = \lim_{n\to\infty} \frac{1}{n+1} \sum_{i=0}^{n} f(\omega_1, t_i)$ for every $f \in C_b(X)$, but that $\langle (\omega_1, t_i) \rangle_{i\in\mathbb{N}}$ is not equidistributed with respect to μ.

(e) Let $(X, \mathfrak{T}, \Sigma, \mu)$ be a topological measure space. Let $\mathcal{E}$ be the Jordan algebra of X (411Yc). (i) Suppose that μ is a complete probability measure on X and $\langle x_n \rangle_{n\in\mathbb{N}}$ an equidistributed sequence in X. Show that the asymptotic density $d(\{n : x_n \in E\})$ is defined and equal to μE for every $E \in \mathcal{E}$. (ii) Suppose that μ is a probability measure on X and that $\langle x_n \rangle_{n\in\mathbb{N}}$ is a sequence in X such that $d(\{n : x_n \in E\})$ is defined and equal to μE for every $E \in \mathcal{E}$. Show that $\lim_{n\to\infty} \frac{1}{n+1} \sum_{i=0}^{n} f(x_i) = \int f d\mu$ for every $f \in C_b(X)$.

(f) Show that a sequence $\langle x_n \rangle_{n\in\mathbb{N}}$ in $[0,1]$ is equidistributed for Lebesgue measure iff there is some $r_0 \in \mathbb{N}$ such that $\lim_{n\to\infty} \frac{1}{n+1} \sum_{i=0}^{n} x_i^r = \frac{1}{r+1}$ for every $r \geq r_0$.

(g) Show that a Radon measure on an extremally disconnected compact Hausdorff space has an equidistributed sequence iff it is point-supported. (*Hint*: see the hint for 326Yo.)

(h) Show that there is a countable dense set $D \subseteq [0,1]^{\mathfrak{c}}$ such that no sequence in D is equidistributed for the usual measure on $[0,1]^{\mathfrak{c}}$.

(i) Let X be a compact Hausdorff topological group. Show that a sequence $\langle x_n \rangle_{n\in\mathbb{N}}$ in X is equidistributed for the Haar probability measure on X iff $\lim_{n\to\infty} \frac{1}{n+1} \sum_{i=0}^{n} \phi(x_i) = 0$ for every non-trivial finite-dimensional representation ϕ of X. (*Hint*: 446Yb.)

(j) Show that $\mathfrak{Z}$ is weakly σ-distributed.

(k) Show that $\mathfrak{Z} \cong \mathfrak{Z}^{\mathbb{N}}$.

(l) Show that $\mathfrak{Z}$ has the σ-interpolation property (definition: 466G).

(m) Let $\langle X_\xi \rangle_{\xi<\mathfrak{c}}$ be a family of topological spaces with countable networks consisting of Borel sets, and μ a τ-additive topological probability measure on $X = \prod_{\xi<\mathfrak{c}} X_\xi$. Show that μ has an equidistributed sequence.

491Z Problem It is known that for almost every $x > 1$ the sequence $\langle < x^n > \rangle_{n\in\mathbb{N}}$ of fractional parts of powers of x is equidistributed for Lebesgue measure on $[0,1]$ (Kuipers & Niederreiter 74, p. 35). But is $\langle < (\frac{3}{2})^n > \rangle_{n\in\mathbb{N}}$ equidistributed?

491 Notes and comments The notations d^*, d (491A) are standard, and usefully suggestive. But coming from measure theory we have to remember that d^*, although a submeasure, is not an outer measure, the domain of d is not an algebra of sets (491Xa), and d and d^* are related by only one of the formulae we expect to connect a measure with an outer measure (491Ac, 491Xd). The limits $\lim_{n\to\infty} \frac{1}{n}\sum_{i=0}^{n} f(x_i)$ are the **Cesaro means** of the sequences $\langle f(x_n)\rangle_{n\in\mathbb{N}}$. The delicacy of the arguments here arises from the fact that the family of (bounded) sequences with Cesaro means, although a norm-closed linear subspace of ℓ^∞, is neither a sublattice nor a subalgebra. When we turn to the quotient algebra $\mathfrak{Z} = \mathcal{P}\mathbb{N}/\mathcal{Z}$, we find ourselves with a natural submeasure to which we can apply results from §393 to good effect (491I). What is striking is that equidistributed sequences induce regular embeddings of measure algebras in $\mathfrak{Z}$ which can be thought of as measure-preserving (491N).

Most authors have been content to define an 'equidistributed sequence' to be one such that the integrals of bounded continuous functions are correctly specified (491Cf, 491Cg); that is, that the point-supported measures $\frac{1}{n+1}\sum_{i=0}^{n} \delta_{x_i}$ converge to μ in the vague topology on an appropriate class of measures (437J). I am going outside this territory in order to cover some ideas I find interesting. 491Xi shows that it makes a difference; there are Borel measures on compact Hausdorff spaces which have sequences which give the correct Cesaro means for continuous functions, but lie within negligible closed sets; and the same can happen with Baire measures (491Yd). It seems to be difficult, in general, to determine whether a topological probability space – even a compact Radon probability space – has an equidistributed sequence. In the proofs of 491D-491G I have tried to collect the principal techniques for showing that spaces do have equidistributed sequences. In the other direction, it is obviously impossible for a space to have an equidistributed sequence if every separable subspace is negligible (491Xm). For an example of a separable compact Hausdorff space with a Radon measure which does not have an equidistributed sequence, we seem to have to go deeper (491Yg).

491Z is a famous problem. It is not clear that it is a problem in measure theory, and there is no reason to suppose that any of the ideas of this treatise beyond 491Xf(i) are relevant. I mention it because I think everyone should know that it is there.

492 Combinatorial concentration of measures

'Concentration of measure' takes its most dramatic form in the geometrically defined notions of concentration explored in §476. But the phenomenon is observable in many other contexts, if we can devise the right abstract geometries to capture it. In this section I present one of Talagrand's theorems on the concentration of measure in product spaces, using the Hamming metric (492D), and Maurey's theorem on concentration of measure in permutation groups (492H).

492A Lemma Let (X, Σ, μ) be a totally finite measure space, $\alpha < \beta$ in $\mathbb{R}$, $\phi : [\alpha, \beta] \to \mathbb{R}$ a convex function, and $f : X \to [\alpha, \beta]$ a Σ-measurable function. Then

$$\int \phi(f(x))\mu(dx) \leq \tfrac{\phi(\beta)-\phi(\alpha)}{\beta-\alpha} \int f d\mu + \tfrac{\beta\phi(\alpha)-\alpha\phi(\beta)}{\beta-\alpha}\mu X.$$

proof If $t \in [\alpha, \beta]$ then $t = \frac{t-\alpha}{\beta-\alpha}\beta + \frac{\beta-t}{\beta-\alpha}\alpha$, so

$$\phi(t) \leq \tfrac{t-\alpha}{\beta-\alpha}\phi(\beta) + \tfrac{\beta-t}{\beta-\alpha}\phi(\alpha) = \tfrac{\phi(\beta)-\phi(\alpha)}{\beta-\alpha}t + \tfrac{\beta\phi(\alpha)-\alpha\phi(\beta)}{\beta-\alpha}.$$

Accordingly

$$\phi(f(x)) \leq \tfrac{\phi(\beta)-\phi(\alpha)}{\beta-\alpha}f(x) + \tfrac{\beta\phi(\alpha)-\alpha\phi(\beta)}{\beta-\alpha}$$

for every $x \in X$; integrating with respect to x, we have the result.

492B Corollary Let (X, Σ, μ) be a probability space and $f : X \to [\alpha, 1]$ a measurable function, where $0 < \alpha \leq 1$. Then $\int \frac{1}{f} d\mu \cdot \int f d\mu \leq \frac{(1+\alpha)^2}{4\alpha}$.

proof Set $\gamma = \int f d\mu$, so that $\alpha \leq \gamma \leq 1$. By 492A, with $\phi(t) = \frac{1}{t}$,

$$\int \frac{1}{f} d\mu \leq \frac{\gamma}{1-\alpha}(1 - \frac{1}{\alpha}) + \frac{1}{1-\alpha}(\frac{1}{\alpha} - \alpha) = \frac{1+\alpha-\gamma}{\alpha}.$$

Now $\frac{1+\alpha-\gamma}{\alpha} \cdot \gamma$ takes its maximum value $\frac{(1+\alpha)^2}{4\alpha}$ when $\gamma = \frac{1+\alpha}{2}$, so this is also the maximum possible value for $\int 1/f \cdot \int f$.

492C Lemma $\frac{1}{2}(1 + \cosh t) \leq e^{t^2/4}$ for every $t \in \mathbb{R}$.

proof For $k \geq 1$, $4^k k! \leq 2(2k)!$ (induce on k), so

$$1 + \cosh t = 2 + \sum_{k=1}^{\infty} \frac{t^{2k}}{(2k)!} \leq 2 + \sum_{k=1}^{\infty} \frac{2t^{2k}}{4^k k!} = 2e^{t^2/4}.$$

492D Theorem (TALAGRAND 95) Let $\langle (X_i, \Sigma_i, \mu_i) \rangle_{i<n}$ be a non-empty finite family of probability spaces with product (X, Λ, λ). Let ρ be the **normalized Hamming metric** on X defined by setting $\rho(x, y) = \frac{1}{n}\#(\{i : i < n, x(i) \neq y(i)\})$ for x, $y \in X$. If $W \in \Lambda$ and $\lambda W > 0$, then

$$\overline{\int} e^{t\rho(x,W)} \lambda(dx) \leq \frac{1}{\lambda W} e^{t^2/4n}$$

for every $t \geq 0$.

proof The formulae below will go much more smoothly if we work with the simple Hamming metric $\sigma(x, y) = \#(\{i : x(i) \neq y(i)\}$ instead of ρ. In this case, we can make sense of the case $n = 0$, and this will be useful. In terms of σ, our target is to prove that if $W \in \Lambda$ and $\lambda W > 0$, then

$$\overline{\int} e^{t\sigma(x,W)} \lambda(dx) \leq \frac{1}{\lambda W} e^{nt^2/4}$$

for every $t \geq 0$.

(a) To begin with, suppose that every $X_i = Z = \{0, 1\}^{\mathbb{N}}$, every μ_i is a Borel measure, and W is compact. Note that in this case λ is a Radon measure (because the X_i are compact and metrizable), and

$$\{x : \sigma(x, W) \leq m\} = \bigcup_{I \subseteq n, \#(I) \leq m} \{x : \exists\, y \in W,\, x\restriction n \setminus I = y\restriction n \setminus I\}$$

is compact for every m, so the function $x \mapsto \sigma(x, W)$ is measurable.

Induce on n. If $n = 0$ we must have $W = X = \{\emptyset\}$ and $\sigma(x, W) = 0$ for every x, so the result is trivial. For the inductive step to $n \geq 1$, we have $W \subseteq X \times X_n$, where $X = \prod_{i<n} X_i$, and we are looking at $\iint e^{t\sigma((x,\xi),W)} \lambda(dx) \mu_n(d\xi)$. Now, setting $V_\xi = \{x : (x, \xi) \in W\}$ for $\xi \in X_n$, $V = \{x : \exists\, \xi \in X_n,\, (x, \xi) \in W\}$, we have

$$\sigma((x, \xi), W) \leq \min(\sigma(x, V_\xi), 1 + \sigma(x, V))$$

for all x and ξ, counting $\sigma(x, \emptyset)$ as ∞ if V_ξ is empty. So, for any $\xi \in X_n$,

$$\begin{aligned}\int e^{t\sigma((x,\xi),W)} \lambda(dx) &\leq \min(\int e^{t\sigma(x,V_\xi)} \lambda(dx), e^t \int e^{t\sigma(x,V)} \lambda(dx)) \\ &\leq e^{nt^2/4} \min(\frac{1}{\lambda V_\xi}, \frac{e^t}{\lambda V})\end{aligned}$$

by the inductive hypothesis, counting $\min(\frac{1}{0}, \frac{e^t}{\lambda V})$ as $\frac{e^t}{\lambda V}$.

It follows that if we set $f(\xi) = \max(e^{-t}, \frac{\lambda V_\xi}{\lambda V})$ for $\xi \in X_n$,

$$\begin{aligned}(\lambda\times\mu_n)(W)\int e^{t\sigma((x,\xi),W)}\lambda(dx)\mu_n(d\xi)&\\ &\le \int \lambda V_\xi \mu_n(d\xi)\cdot e^{nt^2/4}\int \min(\tfrac{1}{\lambda V_\xi},\tfrac{e^t}{\lambda V})\mu_n(d\xi)\\ &= e^{nt^2/4}\int \tfrac{\lambda V_\xi}{\lambda V}\mu_n(d\xi)\cdot\int \min(e^t,\tfrac{\lambda V}{\lambda V_\xi})\mu_n(d\xi)\\ &\le e^{nt^2/4}\int f(\xi)\mu_n(d\xi)\cdot\int \tfrac{1}{f(\xi)}\mu_n(d\xi)\\ &\le e^{nt^2/4}\cdot\tfrac{(1+e^{-t})^2}{4e^{-t}}\end{aligned}$$

(492B)

$$= \tfrac{1}{2}e^{nt^2/4}(1+\cosh t)\le e^{(n+1)t^2/4}$$

by 492C, and

$$\int e^{t\sigma((x,\xi),W)}\lambda(dx)\mu_n(d\xi)\le \frac{1}{(\lambda\times\mu_n)(W)}e^{(n+1)t^2/4},$$

so the induction continues.

(b) Now turn to the general case. If $W\in\Lambda$, there is a $W_1\subseteq W$ such that $W_1\in\widehat{\bigotimes}_{i<n}\Sigma_i$ and $\lambda W_1=\lambda W$ (254Ff). There must be countably-generated σ-subalgebras Σ_i' of Σ_i such that $W_1\in\widehat{\bigotimes}_{i<n}\Sigma_i'$. For each $i<n$, let $\langle E_{ik}\rangle_{k\in\mathbb{N}}$ be a sequence in Σ_i generating Σ_i', and let $h_i:X_i\to Z$ be the corresponding Marczewski functional, so that $h_i(\xi)=\langle\chi E_{ik}(\xi)\rangle_{k\in\mathbb{N}}$ for $\xi\in X_i$. Let μ_i' be the Borel measure on Z defined by setting $\mu_i'F=\mu_i h_i^{-1}[F]$ for every Borel set $F\subseteq Z$, and let ν be the product of the measures μ_i' on $Y=Z^n$. If we set $h(x)=\langle h_i(x(i))\rangle_{i<n}$ for $x\in X$, then $h:X\to Y$ is inverse-measure-preserving for λ and ν (254H). Moreover, by the choice of the E_{ik}, $W_1=h^{-1}[V]$ for some Borel set $V\subseteq Y$.

Because Y is a compact metrizable space, ν is the completion of a Borel measure and is a Radon measure (433Cb). For each $I\subseteq n$, write ν_I for the product measure on Z^I, and set

$$V_I=\{u:u\in Z^{n\setminus I},\ \nu_I\{v:v\in Z^I,\ (u,v)\in V\}>0\},$$

$$V_I'=\{y:y\in Y,\ y\restriction n\setminus I\in V_I\}.$$

Then $\nu(V\setminus V_I')=0$ for every $I\subseteq n$, so if we set $V'=\bigcap_{I\subseteq n}V_I'$ then $\nu V'=\nu V$. (Of course $V'\subseteq V_\emptyset'=V$.)

Take any $\gamma\in\,]0,\lambda W[\,=\,]0,\nu V'[$. Let $K\subseteq V'$ be a compact set such that $\nu K\ge\gamma$. Set $g(y)=e^{t\sigma(y,K)}$ for $y\in Y$, where I write σ for the Hamming metric on Y (regarded as a product of n factor spaces). Then $g:Y\to\mathbb{R}$ is Borel measurable and $gh:X\to\mathbb{R}$ is Λ-measurable. Also, for any $x\in X$, $\sigma(x,W)\le\sigma(h(x),K)$. **P** Take $y\in K$ such that $\sigma(h(x),y)=\sigma(h(x),K)$, and set

$$I=\{i:h(x)(i))\ne y(i)\},\quad u=h(x)\restriction n\setminus I=y\restriction n\setminus I.$$

Because $y\in V'$, $u\in V_I$ and $\nu_I H>0$, where $H=\{v:v\in Z^I,\ (u,v)\in V\}$. But if we write λ_I for the product measure on $\prod_{i\in I}X_i$, and $h_I(z)=\langle h_i(z(i))\rangle_{i\in I}$ for $z\in\prod_{i\in I}X_i$, then h_I is inverse-measure-preserving for λ_I and ν_I; in particular, $h_I^{-1}[H]$ is non-empty. This means that we can find an $x'\in X$ such that $x'\restriction n\setminus I=x\restriction n\setminus I$ and $x'\restriction I\in h_I^{-1}[H]$. In this case, $h(x')\in V$, so $x'\in W_1\subseteq W$, and

$$\sigma(x,W)\le\sigma(x,x')\le\#(I)=\sigma(h(x),K).\ \textbf{Q}$$

Accordingly

$$e^{t\sigma(x,W)}\le e^{t\sigma(h(x),K)}=g(h(x))$$

for every $x\in X$, and

$$\overline{\int}e^{t\sigma(x,W)}\lambda(dx)\le\int gh\,d\lambda=\int g\,d\nu$$

(because g is ν-integrable and h is inverse-measure-preserving, see 235I)

$$\leq \frac{1}{\nu K} e^{nt^2/4}$$

(by (a))

$$\leq \frac{1}{\gamma} e^{nt^2/4}.$$

As γ is arbitrary,

$$\overline{\int} e^{t\sigma(x,W)} \lambda(dx) \leq \frac{1}{\lambda W} e^{nt^2/4},$$

as claimed.

492E Corollary (TALAGRAND 95) Let $\langle (X_i, \Sigma_i, \mu_i) \rangle_{i<n}$ be a non-empty finite family of probability spaces with product (X, Λ, λ).

(a) Let ρ be the normalized Hamming metric on X. If $W \in \Lambda$ and $\lambda W > 0$, then

$$\lambda^*\{x : \rho(x, W) \geq \gamma\} \leq \frac{1}{\lambda W} e^{-n\gamma^2}$$

for every $\gamma \geq 0$.

(b) If W, $W' \in \Lambda$ and $\gamma > 0$ are such that $e^{-n\gamma^2} < \lambda W \cdot \lambda W'$ then there are $x \in W$, $x' \in W'$ such that $\#(\{i : i < n, x(i) \neq x'(i)\}) < n\gamma$.

proof (a) Set $t = 2n\gamma$. By 492D, there is a measurable function $f : X \to \mathbb{R}$ such that $f(x) \geq e^{t\rho(x,W)}$ for every $x \in X$ and $\int f d\lambda \leq \frac{1}{\lambda W} e^{t^2/4n}$. Then

$$\begin{aligned}\lambda^*\{x : \rho(x, W) \geq \gamma\} &\leq \lambda\{x : f(x) \geq e^{t\gamma}\} \leq e^{-t\gamma} \int f d\lambda \\ &\leq \frac{1}{\lambda W} e^{-t\gamma + t^2/4n} = \frac{1}{\lambda W} e^{-n\gamma^2}.\end{aligned}$$

(b) By (a), $\lambda^*\{x : \rho(x, W') \geq \gamma\} < \lambda W$, so there must be an $x \in W$ such that $\rho(x, W') < \gamma$.

492F The next theorem concerns concentration of measure in permutation groups. I approach this through a general result about slowly-varying martingales (492G).

Lemma $e^t \leq t + e^{t^2}$ for every $t \in \mathbb{R}$.

proof If $t \geq 1$ then $t \leq t^2$ so

$$e^t \leq e^{t^2} \leq t + e^{t^2}.$$

If $0 \leq t \leq 1$ then

$$\begin{aligned}e^t = 1 + t + \sum_{n=2}^{\infty} \frac{t^n}{n!} &\leq 1 + t + \sum_{k=1}^{\infty} (\frac{1}{(2k)!} + \frac{1}{(2k+1)!}) t^{2k} \\ &\leq 1 + t + \sum_{k=1}^{\infty} \frac{t^{2k}}{k!} = t + e^{t^2}.\end{aligned}$$

If $t \leq 0$ then

$$\begin{aligned}e^t = 1 + t + \sum_{n=2}^{\infty} \frac{t^n}{n!} &\leq 1 + t + \sum_{k=1}^{\infty} \frac{t^{2k}}{(2k)!} \\ &\leq 1 + t + \sum_{k=1}^{\infty} \frac{t^{2k}}{k!} = t + e^{t^2}.\end{aligned}$$

492G Lemma (MILMAN & SCHECHTMAN 86) Let (X, Σ, μ) be a probability space, and $\langle f_n \rangle_{n\in\mathbb{N}}$ a martingale on X. Suppose that $f_n \in \mathcal{L}^\infty(\mu)$ for every n, and set $\alpha_n = \text{ess sup}\,|f_n - f_{n-1}|$ for $n \geq 1$. Then for any $n \geq 1$ and $\gamma \geq 0$,

$$\Pr(f_n - f_0 \geq \gamma) \leq \exp(-\gamma^2/4\textstyle\sum_{i=1}^n \alpha_i^2),$$

interpreting $\exp(-\gamma^2/0)$ as 0 if $f_n =_{\text{a.e.}} f_0$.

proof Let $\langle \Sigma_n \rangle_{n\in\mathbb{N}}$ be a non-decreasing sequence of σ-subalgebras of Σ to which $\langle f_n \rangle_{n\in\mathbb{N}}$ is a adapted. Extending the functions f_n if necessary, we may suppose that they are all defined on the whole of X.

(a) I show first that

$$\mathbb{E}(\exp(\lambda(f_n - f_0))) \leq \exp(\lambda^2 \textstyle\sum_{i=1}^n \alpha_i^2)$$

for any $n \geq 0$ and any $\lambda > 0$. **P** Induce on n. For $n = 0$, interpreting $\sum_{i=1}^0$ as 0, this is trivial. For the inductive step to $n+1$, set $g = f_n - f_{n-1}$ and let g_1, g_2 be conditional expectations of $\exp(\lambda g)$ and $\exp(\lambda^2 g^2)$ on Σ_{n-1}. Because $|g| \leq \alpha_n$ a.e., $\exp(\lambda^2 g^2) \leq \exp(\lambda^2 \alpha_n^2)$ a.e. and $g_2 \leq \exp(\lambda^2 \alpha_n^2)$ a.e. Because $\exp(\lambda g) \leq \lambda g + \exp(\lambda^2 g^2)$ wherever g is defined (492F), and 0 is a conditional expectation of g on Σ_{n-1}, $g_1 \leq g_2 \leq \exp(\lambda^2 \alpha_n^2)$ a.e.

Now observe that $f_{n-1} - f_0$ is Σ_{n-1}-measurable, so that $\exp(\lambda(f_{n-1} - f_0)) \times g_1$ is a conditional expectation of $\exp(\lambda(f_{n-1} - f_0)) \times \exp(\lambda g) = \exp(\lambda(f_n - f_0))$ on Σ_{n-1} (233Eg). Accordingly

$$\begin{aligned}
\mathbb{E}(\exp(\lambda(f_n - f_0))) &= \mathbb{E}(\exp(\lambda(f_{n-1} - f_0)) \times g_1) \\
&\leq \text{ess sup}\,|g_1| \cdot \mathbb{E}(\exp(\lambda(f_{n-1} - f_0))) \\
&\leq \exp(\lambda^2 \alpha_n^2) \exp(\lambda^2 \sum_{i=1}^{n-1} \alpha_i^2)
\end{aligned}$$

(by the inductive hypothesis)

$$= \exp(\lambda^2 \sum_{i=1}^{n} \alpha_i^2)$$

and the induction continues. **Q**

(b) Now take $n \geq 1$ and $\gamma \geq 0$. If $\sum_{i=1}^n \alpha_i^2 = 0$ then $f_n =_{\text{a.e.}} f_0$ and the result is trivial. Otherwise, set $\lambda = \gamma/2\sum_{i=1}^n \alpha_i^2$. Then

$$\begin{aligned}
\Pr(f_n - f_0 \geq \gamma) &= \Pr(\exp(\lambda(f_n - f_0)) \geq e^{\lambda\gamma}) \\
&\leq e^{-\lambda\gamma}\mathbb{E}(\exp(\lambda(f_n - f_0))) \leq e^{-\lambda\gamma} \exp(\lambda^2 \sum_{i=1}^{n} \alpha_i^2)
\end{aligned}$$

(by (a) above)

$$= e^{-\lambda\gamma/2} = \exp(-\gamma^2/4 \sum_{i=1}^{n} \alpha_i^2)$$

as claimed.

492H Theorem (MAUREY 79) Let X be a non-empty finite set and G the group of all permutations of X with the discrete topology. For π, $\phi \in G$ set

$$\rho(\pi, \phi) = \frac{\#(\{x : x \in X, \pi(x) \neq \phi(x)\})}{\#(X)}.$$

Then ρ is a metric on G. Give G its Haar probability measure, and let $f : G \to \mathbb{R}$ be a 1-Lipschitz function. Then

$$\Pr(f - \mathbb{E}(f) \geq \gamma) \leq \exp(-\frac{\gamma^2 \#(X)}{16})$$

for any $\gamma \geq 0$.

proof We may suppose that $X = n = \{0, \dots, n-1\}$ where $n = \#(X)$. For $m \leq n$, $p : m \to n$ set $A_p = \{\pi : \pi \in G, \pi\restriction m = p\}$, and let Σ_m be the subalgebra of $\mathcal{P}G$ generated by $\{A_p : p \in n^m\}$. Then

$$\{\emptyset, G\} = \Sigma_0 \subseteq \Sigma_1 \subseteq \ldots \subseteq \Sigma_{n-1} = \Sigma_n = \mathcal{P}G;$$

for $m > n$ set $\Sigma_m = \mathcal{P}G$. For each m let f_m be the (unique) conditional expectation of f on Σ_m, so that

$$f_m(\pi) = \frac{1}{\#(A_p)} \sum_{\phi \in A_p} f(\phi)$$

whenever $\pi \in G$ and $p = \pi\restriction m$. Now we find that $|f_m(\pi) - f_{m-1}(\pi)| \leq \frac{2}{n}$ for every $m \geq 1$ and $\pi \in G$. **P** If $m > n$ this is trivial. Otherwise, set $p = \pi\restriction m - 1$ and $k = \pi(m-1)$. Set $J = p[m-1] = \{\pi(i) : i < m-1\}$, and for $j \in n \setminus J$ let $p_j = p^\frown j$ be that function from m to n which extends p and takes the value j at $m-1$; let α_j be the common value of $f_m(\phi)$ for $\phi \in A_{p_j}$, so that $f_m(\pi) = \alpha_k$. Now, for each $j \in n \setminus (J \cup \{k\})$, the function $\phi \mapsto (\overleftarrow{j\,k})\phi$ is a bijection from A_{p_k} to A_{p_j}, where $(\overleftarrow{j\,k}) \in G$ is the transposition which exchanges j and k. But this means that

$$\begin{aligned}
|\alpha_j - \alpha_k| &= \big|\tfrac{1}{(n-m)!} \sum_{\phi \in A_{p_j}} f(\phi) - \tfrac{1}{(n-m)!} \sum_{\phi \in A_{p_k}} f(\phi)\big| \\
&= \tfrac{1}{(n-m)!}\big| \sum_{\phi \in A_{p_j}} f(\phi) - f((\overleftarrow{j\,k})\phi)\big| \\
&\leq \sup_{\phi \in A_{p_j}} \big|f(\phi) - f((\overleftarrow{j\,k})\phi)\big| \leq \frac{2}{n}
\end{aligned}$$

because f is 1-Lipschitz and $\rho(\phi, (\overleftarrow{j\,k})\phi) = \frac{2}{n}$ for every ϕ. And this is true for every $j \in n \setminus (J \cup \{k\})$.

Accordingly

$$\begin{aligned}
|f_{m-1}(\pi) - f_m(\pi)| &= \big|\tfrac{1}{(n-m+1)!} \sum_{\phi \in A_p} f(\phi) - \alpha_k\big| = \big|\tfrac{1}{n-m+1} \sum_{j \in n \setminus J} \alpha_j - \alpha_k\big| \\
&\leq \tfrac{1}{n-m+1} \sum_{j \in n \setminus J} |\alpha_j - \alpha_k| \leq \tfrac{1}{n-m+1} \sum_{j \in n \setminus J} \frac{2}{n} = \frac{2}{n},
\end{aligned}$$

as claimed. **Q**

(b) Now observe that $f = f_{n-1}$ and that f_0 is the constant function with value $\mathbb{E}(f)$, so that

$$\Pr(f - \mathbb{E}(f) \geq \gamma) = \Pr(f_{n-1} - f_0 \geq \gamma) \leq \exp(-\gamma^2/4 \sum_{i=1}^{n-1} (\frac{2}{n})^2)$$

(492G)

$$\leq \exp(-\frac{n\gamma^2}{16}),$$

which is what we were seeking to prove.

492I Corollary Let X be a non-empty finite set and G the group of all permutations of X; write $n = \#(X)$. Let μ be the Haar probability measure of G when given its discrete topology. Suppose that $A \subseteq G$ and $\mu A \geq \frac{1}{2}$. Then

$$\mu\{\pi : \pi \in G, \exists\, \phi \in A, \#(\{x : x \in X, \pi(x) \neq \phi(x)\}) \leq k\} \geq 1 - \exp(-\frac{k^2}{64n})$$

for every $k \leq n$.

proof If $\exp(-\frac{k^2}{64n}) \geq \frac{1}{2}$, this is trivial, since the left-hand-side of the inequality is surely at least $\frac{1}{2}$. Otherwise, set $g(\pi) = \frac{1}{n}\min_{\phi\in A}\#(\{x : x \in X, \pi(x) \neq \phi(x)\})$ for $\pi \in G$, so that g is 1-Lipschitz for the metric ρ of 492H. Applying 492H to $f = -g$, we see that

$$\Pr(\mathbb{E}(g) - g \geq \frac{k}{2n}) \leq \exp(-\frac{k^2}{64n}) < \frac{1}{2},$$

and there must be some $\pi \in A$ such that $\mathbb{E}(g) - g(\pi) < \frac{k}{2n}$, so that $\mathbb{E}(g) < \frac{k}{2n}$. This means that

$$\begin{aligned}\mu\{\pi : \pi \in G, \exists\, \phi \in A, \#(\{x : x \in X, \pi(x) \neq \phi(x)\}) \leq k\}&\\ &= 1 - \mu\{\pi : \pi \in G, g(\pi) > \frac{k}{n}\}\\ &\geq 1 - \Pr(g - \mathbb{E}(g) \geq \frac{k}{2n}) \geq 1 - \exp(-\frac{k^2}{64n}),\end{aligned}$$

applying 492H to g itself.

492X Basic exercises (a) Let (X, Σ, μ) be a probability space, and $\langle f_n\rangle_{n\in\mathbb{N}}$ a martingale on X. Suppose that $f_n \in \mathcal{L}^\infty(\mu)$ for every n, and that $\sigma = \sqrt{\sum_{n=1}^\infty \alpha_n^2}$ is finite and not zero, where $\alpha_n = \operatorname{ess\,sup}|f_n - f_{n-1}|$ for $n \geq 1$. Show that $f = \lim_{n\to\infty} f_n$ is defined a.e., and that $\Pr(f - f_0 \geq \gamma) \leq \exp(-\gamma^2/4\sigma^2)$ for every $\gamma \geq 0$. (*Hint*: show first that $\|f_n\|_1 \leq \|f_n\|_2 \leq \sigma + \|f_0\|_2$ for every n, so that we can apply 275G.)

(b) Let (X, ρ) be a metric space and μ a topological probability measure on X. Suppose that $\gamma, \epsilon > 0$ are such that $\Pr(f - \mathbb{E}(f) \geq \gamma) \leq \epsilon$ whenever $f : X \to [-\gamma, \gamma]$ is 1-Lipschitz. Show that if $\mu F \geq \frac{1}{2}$ then $\mu\{x : \rho(x, F) \geq 2\gamma\} \leq \epsilon$.

(c) Let (X, ρ) be a metric space and μ a topological probability measure on X. Suppose that $\gamma, \epsilon > 0$ are such that $\mu\{x : \rho(x, F) > \gamma\} \leq \epsilon$ whenever $\mu F \geq \frac{1}{2}$. Show that if $f : X \to [-1, 1]$ is a 1-Lipschitz function then $\Pr(f - \mathbb{E}(f) > 2\gamma + 2\epsilon) \leq \epsilon$.

(d) Use 492G to show that if $\langle(X_i, \Sigma_i, \mu_i)\rangle_{i<n}$ is a non-empty finite family of probability spaces with product (X, Λ, λ), and X is given its normalized Hamming metric, and $f \in \mathcal{L}^\infty(\lambda)$ is 1-Lipschitz, then $\Pr(f - \mathbb{E}(f) \geq \gamma) \leq e^{-n\gamma^2/4}$ for every $\gamma \geq 0$. (*Hint*: if $\Sigma_k \subseteq \Lambda$ is the σ-algebra of subsets of X determined by coordinates in k, and f_k is a conditional expectation of f on Σ_k, then $\operatorname{ess\,sup}|f_{k+1} - f_k| \leq \frac{1}{n}$.)

492 Notes and comments In metric spaces, we can say that a probability measure is 'concentrated' if every Lipschitz function f is almost constant in the sense that, for some α, the sets $\{x : |f(x) - \alpha| \geq \gamma\}$ have small measure. What is astonishing is that this does not mean that the measure itself is concentrated on a small set. In 492H, the measure is the Haar probability measure, spread as evenly as it well could be. Of course, when I say that $\{x : |f(x) - \alpha| \geq \gamma\}$ has 'small' measure, I have to let some other parameter – in 492H, the size of X – vary, while γ itself is fixed. Also the shapes of the formulae depend on which normalizations we choose (observe the effect of moving from ρ to σ in the proof of 492D). But the value of 492H is that it gives a strong bound which is independent of the particular function f, provided that it is 1-Lipschitz. This kind of concentration of measure can be described either in terms of the variation of Lipschitz functions from their means or in terms of the measures of neighbourhoods of sets of measure $\frac{1}{2}$ (492Xb-492Xc). The latter, in a more abstract context, is what is described by the concentration functions of measures on uniform spaces (493D).

The martingale method can be used to prove a version of 492E (492Xd). The method of 492D gives a better exponent ($e^{-n\gamma^2}$ in place of $e^{-n\gamma^2/4}$) and also information of a slightly different kind, in that it can be applied directly to sets W of small measure, at least provided that $\gamma > \frac{1}{\sqrt{n}}$ in 492E. We also need a little more measure theory here, since sets which are measured by product measures can be geometrically highly irregular, and our Lipschitz functions $x \mapsto \rho(x, W)$ need not be measurable.

In the proof of 492G we have an interesting application of the idea of 'martingale'. The inequality here is quite different from the standard martingale inequalities like 275D or 275F or 275Yc. It gives a very

strong inequality concerning the difference $f_n - f_0$, at the cost of correspondingly strong hypotheses on the differences $f_i - f_{i-1}$; but since we need control of $\sum_i \text{ess sup} |f_i - f_{i-1}|^2$, not of $\sum_i \text{ess sup} |f_i - f_{i-1}|$, there is scope for applications like 492H. What the inequality tells us is that most of the time the differences $f_i - f_{i-1}$ cancel out, just as in the Central Limit Theorem, and that once again we have a vaguely Gaussian sum $f_n - f_0$.

Concentration of measure, in many forms, has been studied intensively in the context of the geometry of normed spaces, as in MILMAN & SCHECHTMAN 86, from which 492F-492I are taken.

493 Extremely amenable groups

A natural variation on the idea of 'amenable group' (§449) is the concept of 'extremely amenable' group (493A). Expectedly, most of the ideas of 449C-449E can be applied to extremely amenable groups (493B-493C); unexpectedly, we find not only that there are interesting extremely amenable groups, but that we need some of the central ideas of measure theory to study them. I give a criterion for extreme amenability of a group in terms of the existence of suitably concentrated measures (493D) before turning to four examples: measure algebras under symmetric difference (493E), L^0 spaces (493F), automorphism groups of measure algebras (493H) and isometry groups of spheres in infinite-dimensional Hilbert spaces (493J).

493A Definition Let G be a topological group. Then G is **extremely amenable** or has the **fixed point on compacta property** if every continuous action of G on a compact Hausdorff space has a fixed point.

493B Proposition (a) Let G and H be topological groups such that there is a continuous surjective homomorphism from G onto H. If G is extremely amenable, so is H.

(b) Let G be a topological group and suppose that there is a dense subset A of G such that every finite subset of A is included in an extremely amenable subgroup of G. Then G is extremely amenable.

(c) Let G be a topological group with an extremely amenable normal subgroup H such that G/H is extremely amenable. Then G is extremely amenable.

(d) The product of any family of extremely amenable topological groups is extremely amenable.

proof We can use the same arguments as in 449C, with some simplifications.

(a) As in 449Ca, let $\phi : G \to H$ be a continuous surjective homomorphism, X a non-empty compact Hausdorff space and $\bullet : H \times X \to X$ a continuous action. Let $\bullet_1$ be the continuous action of G on X defined by the formula $a\bullet_1 x = \phi(a)\bullet x$. Then any fixed point for $\bullet_1$ is a fixed point for $\bullet$.

(b) Let X be a non-empty compact Hausdorff space and $\bullet$ a continuous action of G on X. For $I \in [A]^{<\omega}$ let H_I be an extremely amenable subgroup of G including I. The restriction of the action to $H_I \times X$ is a continuous action of H_I on X, so

$$\{x : a\bullet x = x \text{ for every } a \in I\} \supseteq \{x : a\bullet x = x \text{ for every } a \in I\}$$

is closed and non-empty. Because X is compact, there is an $x \in X$ such that $a\bullet x = x$ for every $a \in A$. Now $\{a : a\bullet x = x\}$ includes the dense set A, so is the whole of G, and x is fixed under the action of G. As X and $\bullet$ are arbitrary, G is extremely amenable.

(c) Let X be a compact Hausdorff space and $\bullet$ a continuous action of G on X. Set $Q = \{x : x \in X, a\bullet x = x \text{ for every } a \in H\}$; then Q is a closed subset of X and, because H is extremely amenable, is non-empty. Next, $b\bullet x \in Q$ for every $x \in Q$ and $b \in G$. **P** If $a \in H$, then

$$a\bullet(b\bullet x) = (ab)\bullet x = (bb^{-1}ab)\bullet x = b\bullet((b^{-1}ab)\bullet x) = b\bullet x,$$

because H is normal, so $b^{-1}ab \in H$. As a is arbitrary, $b\bullet x \in Q$. **Q** Accordingly we have a continuous action of G on the compact Hausdorff space Q.

If $b \in G$, $a \in H$ and $x \in Q$, then $(ba)\bullet x = b\bullet x$. So we have an action of G/H on Q defined by saying that $b^\bullet\bullet x = b\bullet x$ for every $b \in G$ and $x \in Q$, and this is continuous for the quotient topology on G/H, as in the proof of 449Cc. Because G/H is amenable, there is a point x of Q which is fixed under the action of G/H.

So $b\bullet x = b^\bullet\bullet x = x$ for every $b \in G$, and x is fixed under the action of G. As X and $\bullet$ are arbitrary, G is extremely amenable.

(d) By (c), the product of two extremely amenable topological groups is extremely amenable, since each can be regarded as a normal subgroup of the product. It follows that the product of finitely many extremely amenable topological groups is extremely amenable. Now let $\langle G_i\rangle_{i\in I}$ be any family of extremely amenable topological groups with product G. For finite $J \subseteq I$ let H_J be the set of those $a \in G$ such that $a(i)$ is the identity in G_i for every $i \in I \setminus J$. Then H_J is isomorphic (as topological group) to $\prod_{i\in J} G_i$, so is extremely amenable. Since $\{H_J : J \in [I]^{<\omega}\}$ is an upwards-directed family of subgroups of G with dense union, (b) tells us that G is extremely amenable.

493C Proposition Let G be a topological group. Then G is extremely amenable iff there is a point in the greatest ambit Z of G (definition: 449D) which is fixed by the action of G on Z.

proof Repeat the arguments of 449E(i) $\iff$ (ii), noting that if $z_0 \in Z$ is a fixed point under the action of G on Z, then its images under the canonical maps ϕ of 449Dd will be fixed for other actions.

493D Theorem Let G be a topological group, and $\mathcal{B}$ its Borel σ-algebra. Suppose that for every open neighbourhood V of the identity of G, $\epsilon > 0$, finite set $I \subseteq G$ and finite family $\mathcal{E}$ of zero sets in G there is a finitely additive functional $\nu : \mathcal{B} \to [0,1]$ such that $\nu G = 1$ and

(i) $\nu(VF) \geq 1 - \epsilon$ whenever $F \in \mathcal{E}$ and $\nu F \geq \frac{1}{2}$,

(ii) $|\nu(aF) - \nu F| \leq \epsilon$ for every $F \in \mathcal{E}$ and $a \in I$.

Then G is extremely amenable.

proof (a) Write M for the set of finitely additive functionals $\nu : \mathcal{B} \to [0,1]$ such that $\nu G = 1$. If V is an open neighbourhood of the identity e of G, $\epsilon > 0$, $I \in [G]^{<\omega}$ and $\mathcal{E}$ is a finite family of zero sets in G, let $A(V,\epsilon,I,\mathcal{E})$ be the set of those $\nu \in M$ satisfying (i) and (ii) above. Our hypothesis is that none of these sets $A(V,\epsilon,I,\mathcal{E})$ are empty; since $A(V,\epsilon,I,\mathcal{E}) \subseteq A(V',\epsilon',I',\mathcal{E}')$ whenever $V \subseteq V'$, $\epsilon \leq \epsilon'$, $I \supseteq I'$ and $\mathcal{E} \supseteq \mathcal{E}'$, there is an ultrafilter $\mathcal{F}$ on M containing all these sets.

Let U be the space of bounded real-valued functionals on G which are uniformly continuous for the right uniformity on G. If we identify $L^\infty(\mathcal{B})$ with the space of bounded Borel measurable real-valued functions on G (363Ha), then U is a Riesz subspace of $L^\infty(\mathcal{B})$. For each $\nu \in M$ we have a positive linear functional $\int d\nu : L^\infty(\mathcal{B}) \to \mathbb{R}$ (363L). For $f \in U$ set $z(f) = \lim_{\nu\to\mathcal{F}} \int f d\nu$.

(b) $z : U \to \mathbb{R}$ is a Riesz homomorphism, and $z(\chi G) = 1$. **P** Of course z is a positive linear functional taking the value 1 at χG, just because all the integrals $\int d\nu$ are. Now suppose that f_0, $f_1 \in U$ and $f_0 \wedge f_1 = 0$. Take any $\epsilon > 0$. Then there is an open neighbourhood V of e such that $|f_i(x) - f_i(y)| \leq \epsilon$ whenever $xy^{-1} \in V$ and $i \in \{0,1\}$. Set $F_i = \{x : f_i(x) = 0\}$, $E_i = VF_i$ for each i. Then $F_0 \cup F_1 = X$, so $\nu F_0 + \nu F_1 \geq 1$ for every $\nu \in M$, and there is a $j \in \{0,1\}$ such that $A_0 = \{\nu : \nu F_j \geq \frac{1}{2}\} \in \mathcal{F}$. Next,

$$A_1 = \{\nu\text{: if } \nu F_j \geq \frac{1}{2} \text{ then } \nu(VF_j) \geq 1-\epsilon\}$$

belongs to $\mathcal{F}$. Accordingly $\lim_{\nu\to\mathcal{F}} \nu E_j \geq 1 - \epsilon$. As $f_j(x) \leq \epsilon$ for every $x \in E_j$,

$$z(f_j) = \lim_{\nu\to\mathcal{F}} \int f_j d\nu \leq \epsilon(1 + \|f_j\|_\infty).$$

This shows that $\min(z(f_0), z(f_1)) \leq \epsilon(1 + \|f_1\|_\infty + \|f_2\|_\infty)$. As ϵ is arbitrary, $\min(z(f_0), z(f_1)) = 0$; as f_0 and f_1 are arbitrary, z is a Riesz homomorphism (352G(iv)). **Q**

Thus z belongs to the greatest ambit Z of G.

(c) $a\bullet z = z$ for every $a \in G$. **P** Take any non-negative $f \in U$. For $n \in \mathbb{N}$ set $F_n = \{x : x \in G, f(x) \geq n\epsilon\}$. Set $m = \lfloor \frac{1}{\epsilon}\|f\|_\infty \rfloor$, so that $F_n = \emptyset$ for every $n > m$. Because $\{\nu : |\nu(a^{-1}F_n) - \nu F_n| \leq \delta\} \in \mathcal{F}$ for every $n \in \mathbb{N}$ and every $\delta > 0$, $\lim_{\nu\to\mathcal{F}} \nu F_n = \lim_{\nu\to\mathcal{F}} \nu(a^{-1}F_n)$ for every n. Next, setting $g = \sum_{n=1}^m \epsilon\chi F_n$, we have $g \in L^\infty(\mathcal{B})$ and $g \leq f \leq g + \epsilon\chi G$. Since $a^{-1}\bullet g$ (in the language of 441Ac) is just $\sum_{n=1}^m \epsilon\chi(a^{-1}F_n)$, we have $\lim_{\nu\to\mathcal{F}} \int g\, d\nu = \lim_{\nu\to\mathcal{F}} \int (a^{-1}\bullet g) d\nu$. But also $a^{-1}\bullet g \leq a^{-1}\bullet f \leq a^{-1}\bullet g + \epsilon\chi G$. So

$$|\int f d\nu - \int g\, d\nu| \leq \epsilon, \quad |\int (a^{-1}\bullet f) d\nu - \int (a^{-1}\bullet g) d\nu| \leq \epsilon$$

for every $\nu \in M$. This means that

$$|\lim_{\nu\to\mathcal{F}}\int f d\nu - \lim_{\nu\to\mathcal{F}}\int (a^{-1}\bullet f)d\nu| \leq 2\epsilon.$$

As ϵ is arbitrary,

$$(a\bullet z)(f) = z(a^{-1}\bullet f) = \lim_{\nu\to\mathcal{F}}\int (a^{-1}\bullet f)d\nu = \lim_{\nu\to\mathcal{F}}\int f d\nu = z(f).$$

This is true for every non-negative $f \in U$; as both z and $a\bullet z$ are linear, $(a\bullet z)(f) = z(f)$ for every $f \in U$, and $a\bullet z = z$. **Q**

(d) Thus $z \in Z$ is fixed under the action of G on Z; by 493C, this is enough to ensure that G is extremely amenable.

493E I turn now to examples of extremely amenable groups. The first three are groups which we have already studied for other reasons.

Theorem Let $(\mathfrak{A}, \bar{\mu})$ be an atomless measure algebra. Then $\mathfrak{A}$, with the group operation $\triangle$ and the measure-algebra topology (definition: 323A), is an extremely amenable group.

proof (a) To begin with let us suppose that $(\mathfrak{A}, \bar{\mu})$ is a probability algebra; write σ for the measure metric of $\mathfrak{A}$, so that $\sigma(a, a') = \bar{\mu}(a \triangle a')$ for a, $a' \in \mathfrak{A}$. I seek to apply 493D.

(i) Let V be an open neighbourhood of 0 in $\mathfrak{A}$, $\epsilon > 0$, $I \in [\mathfrak{A}]^{<\omega}$ and $\mathcal{E}$ a finite family of zero sets in $\mathfrak{A}$. Let $\gamma > 0$ be such that $V \supseteq \{a : \bar{\mu}a \leq 2\gamma\}$. Let $\mathfrak{B}_0$ be the finite subalgebra of $\mathfrak{A}$ generated by I and B_0 the set of atoms in $\mathfrak{B}_0$. Set

$$t = \frac{1}{\gamma}\ln\frac{3}{\epsilon}, \quad n = \lceil \max(t^2, \sup_{b\in B_0}\frac{1}{\bar{\mu}b})\rceil.$$

Because $\mathfrak{A}$ is atomless, we can split any member of $\mathfrak{A}\setminus\{0\}$ into two parts of equal measure (331C); if, starting from the disjoint set B_0, we successively split the largest elements until we have a disjoint set B with just n elements, then we shall have $\bar{\mu}b \leq \frac{2}{n}$ for every $b \in B$. We have a natural identification between $\{0,1\}^B$ and the subalgebra $\mathfrak{B}$ of $\mathfrak{A}$ generated by B, matching $x \in \{0,1\}^B$ with $f(x) = \sup\{b : b \in B, x(b) = 1\}$. Writing ρ for the normalized Hamming metric on $\{0,1\}^B$ (492D), we have $\sigma(f(x), f(y)) \leq 2\rho(x, y)$ for all x, $y \in \{0,1\}^B$. **P** Set $J = \{b : b \in B, x(b) \neq y(b)\}$, so that

$$\sigma(f(x), f(y)) = \bar{\mu}(f(x) \triangle f(y)) = \bar{\mu}(\sup J) = \textstyle\sum_{b\in J}\bar{\mu}b \leq \frac{2}{n}\#(J) = 2\rho(x, y).$$ **Q**

(ii) Let λ be the usual measure on $\{0,1\}^B$ and set $\nu E = \lambda f^{-1}[E]$ for every Borel set $E \subseteq \mathfrak{A}$. Then ν is a probability measure. Note that $f : \{0,1\}^B \to \mathfrak{B}$ is a group isomorphism if we give $\{0,1\}^B$ the addition $+_2$ corresponding to its identification with $\mathbb{Z}_2^B$, and $\mathfrak{B}$ the operation $\triangle$. Because λ is translation-invariant for $+_2$, its copy, the subspace measure $\nu_{\mathfrak{B}}$ on the ν-conegligible finite set $\mathfrak{B}$, is translation-invariant for $\triangle$. But this means that $\nu\{b \triangle d : d \in F\} = \nu F$ whenever $b \in \mathfrak{B}$ and $F \subseteq \mathfrak{B}$, and therefore that $\nu\{b \triangle d : d \in F\} = \nu F$ whenever $b \in I$ and $F \in \mathcal{E}$. This shows that ν satisfies condition (ii) of 493D.

(iii) Now suppose that $F \in \mathcal{E}$ and that $\nu F \geq \frac{1}{2}$. Set $W = f^{-1}[F]$, so that $\lambda W \geq \frac{1}{2}$. By 492D,

$$\int e^{t\rho(x,W)}\lambda(dx) \leq 2e^{t^2/4n} \leq 2e^{1/4} \leq 3,$$

so

$$\lambda\{x : \rho(x, W) \geq \gamma\} = \lambda\{x : t\rho(x, W) \geq \ln\tfrac{3}{\epsilon}\} = \lambda\{x : e^{t\rho(x,W)} \geq \tfrac{3}{\epsilon}\} \leq \epsilon.$$

Accordingly

$$\begin{aligned}\nu\{a\triangle d : a \in V, d \in F\} &\geq \nu\{a : \sigma(a, F) \leq 2\gamma\} = \lambda\{x : \sigma(f(x), F) \leq 2\gamma\}\\ &\geq \lambda\{x : \sigma(f(x), f[W]) \leq 2\gamma\} \geq \lambda\{x : \rho(x, W) \leq \gamma\}\end{aligned}$$

(because f is 2-Lipschitz)

$$\geq 1 - \epsilon.$$

So ν also satisfies (i) of 493D.

(iv) Since V, ϵ, I and $\mathcal{E}$ are arbitrary, 493D tells us that $\mathfrak{A}$ is an extremely amenable group, at least when $(\mathfrak{A}, \bar{\mu})$ is an atomless probability algebra.

(b) For the general case, observe first that if $(\mathfrak{A}, \bar{\mu})$ is atomless and totally finite then $(\mathfrak{A}, \triangle)$ is an extremely amenable group; this is trivial if $\mathfrak{A} = \{0\}$, and otherwise there is a probability measure on $\mathfrak{A}$ which induces the same topology, so we can apply (a). For a general atomless measure algebra $(\mathfrak{A}, \bar{\mu})$, set $\mathfrak{A}^f = \{c : c \in \mathfrak{A}, \bar{\mu}c < \infty\}$ and for $c \in \mathfrak{A}^f$ let $\mathfrak{A}_c$ be the principal ideal generated by c. Then $\mathfrak{A}_c$ is a subgroup of $\mathfrak{A}$ and the measure-algebra topology of $\mathfrak{A}_c$, regarded as a measure algebra in itself, is the subspace topology induced by the measure-algebra topology of $\mathfrak{A}$. So $\{\mathfrak{A}_c : c \in \mathfrak{A}^f\}$ is an upwards-directed family of extremely amenable subgroups of $\mathfrak{A}$ with union which is dense in $\mathfrak{A}$, so $\mathfrak{A}$ itself is extremely amenable, by 493Bb. This completes the proof.

493F Theorem (PESTOV P01) Let (X, Σ, μ) be an atomless measure space. Then $L^0(\mu)$, with the group operation $+$ and the topology of convergence in measure, is an extremely amenable group.

proof It will simplify some of the formulae if we move at once to the space $L^0(\mathfrak{A})$, where $(\mathfrak{A}, \bar{\mu})$ is the measure algebra of (X, Σ, μ); for the identification of $L^0(\mathfrak{A})$ with $L^0(\mu)$ see 364Jc; for a note on convergence in measure in $L^0(\mathfrak{A})$, see 367M; of course $\mathfrak{A}$ is atomless if (X, Σ, μ) is (322Bg).

(a) I seek to prove that $S(\mathfrak{A})$, with the group operation of addition and the topology of convergence in measure, is extremely amenable. As in 493E, I start with the case in which $(\mathfrak{A}, \bar{\mu})$ is a probability algebra, and use 493D.

(i) Take an open neighbourhood V of 0 in $S(\mathfrak{A})$, an $\epsilon > 0$, a finite set $I \subseteq S(\mathfrak{A})$ and a finite family $\mathcal{E}$ of zero sets in $S(\mathfrak{A})$. Let $\gamma > 0$ be such that $u \in V$ whenever $u \in S(\mathfrak{A})$ and $\bar{\mu}[\![u \neq 0]\!] \leq 2\gamma$. Let $\mathfrak{B}_0$ be a finite subalgebra of $\mathfrak{A}$ such that I is included in the linear subspace of $S(\mathfrak{A})$ generated by $\{\chi b : b \in \mathfrak{B}_0\}$, and B_0 the set of atoms of $\mathfrak{B}_0$. As in the proof of 493E, set

$$t = \frac{1}{\gamma} \ln \frac{3}{\epsilon}, \quad n = \lceil \max(t^2, \sup_{b \in B_0} \frac{1}{\bar{\mu}b}) \rceil,$$

and let $B \subseteq \mathfrak{A} \setminus \{0\}$ be a partition of unity with n elements, refining B_0, such that $\bar{\mu}b \leq \frac{2}{n}$ for every $b \in B$. We have a natural identification between $\mathbb{R}^B$ and the linear subspace of $S(\mathfrak{A})$ generated by $\{\chi b : b \in B\}$, matching $x \in \mathbb{R}^B$ with $f(x) = \sum_{b \in B} x(b)\chi b$, which is continuous if $\mathbb{R}^B$ is given its product topology. Writing ρ for the normalized Hamming metric on $\mathbb{R}^B$, we have

$$\bar{\mu}[\![f(x) \neq f(y)]\!] = \sum_{x(b) \neq y(b)} \bar{\mu}b \leq \frac{2}{n} \#(\{b : x(b) \neq y(b)\}) = 2\rho(x, y)$$

for all x, $y \in \mathbb{R}^B$.

(ii) Set $\beta = \sup_{v \in I} \|v\|_\infty$ (if $I = \emptyset$, take $\beta = 0$). Let $M > 0$ be so large that $(M + \beta)^n \leq (1 + \frac{1}{2}\epsilon)M^n$. On $\mathbb{R}$, write μ_L for Lebesgue measure and μ'_L for the indefinite-integral measure over μ_L defined by the function $\frac{1}{2M}\chi[-M, M]$, so that $\mu'_L E = \frac{1}{2M}\mu_L(E \cap [-M, M])$ whenever $E \subseteq \mathbb{R}$ and $E \cap [-M, M]$ is Lebesgue measurable. Let λ, λ' be the product measures on $\mathbb{R}^B$ defined from μ_L and μ'_L. Let ν be the Borel probability measure on $S(\mathfrak{A})$ defined by setting $\nu F = \lambda' f^{-1}[F]$ for every Borel set $F \subseteq S(\mathfrak{A})$.

Now $|\nu(v + F) - \nu F| \leq \epsilon$ for every $v \in I$ and Borel set $F \subseteq S(\mathfrak{A})$. **P** Because B refines B_0, v is expressible as $f(y)$ for some $y \in \mathbb{R}^B$; because $\|v\|_\infty \leq \beta$, $|y(b)| \leq \beta$ for every $b \in B$. Because $f : \mathbb{R}^B \to S(\mathfrak{A})$ is linear, $f^{-1}[v + F] = y + f^{-1}[F]$. Now

$$\begin{aligned} |\nu(v + F) - \nu F| &= |\lambda' f^{-1}[v + F] - \lambda' f^{-1}[F]| \\ &= \frac{1}{(2M)^n} \big|\lambda(f^{-1}[v + F] \cap [-M, M]^n) - \lambda(f^{-1}[F] \cap [-M, M]^n)\big| \end{aligned}$$

(use 253I, or otherwise)

$$= \frac{1}{(2M)^n}\big|\lambda((y+f^{-1}[F])\cap[-M,M]^n) - \lambda(f^{-1}[F]\cap[-M,M]^n)\big|$$
$$= \frac{1}{(2M)^n}\big|\lambda(f^{-1}[F]\cap([-M,M]^n - y)) - \lambda(f^{-1}[F]\cap[-M,M]^n)\big|$$
$$\leq \frac{1}{(2M)^n}\lambda(([-M,M]^n - y)\triangle[-M,M]^n)$$
$$= \frac{2}{(2M)^n}\lambda(([-M,M]^n - y)\setminus[-M,M]^n)$$
$$\leq \frac{2}{(2M)^n}\lambda(([-M-\beta,M+\beta]^n\setminus[-M,M]^n)$$
$$= \frac{2}{M^n}((M+\beta)^n - M^n) \leq \epsilon. \blacksquare$$

So ν satisfies (ii) of 493D.

(iii) Now suppose that $F \in \mathcal{E}$ and $\nu F \geq \frac{1}{2}$. Set $W = f^{-1}[F]$, so that $\lambda' W \geq \frac{1}{2}$. Just as in the proof of 493E, $\int e^{t\rho(x,W)}\lambda'(dx) \leq 2e^{t^2/4n} \leq 3$, so

$$\lambda'\{x : \rho(x,W) \geq \gamma\} = \lambda'\{x : e^{t\rho(x,W)} \geq \tfrac{3}{\epsilon}\} \leq \epsilon,$$

and

$$\begin{aligned}\nu\{v+u : v \in V,\, u \in F\} &\geq \nu\{w : \exists\, u \in F,\, \bar\mu[\![u \neq w]\!] \leq 2\gamma\}\\ &\geq \lambda'\{x : \rho(x,W) \leq \gamma\} \geq 1-\epsilon.\end{aligned}$$

So ν also satisfies (i) of 493D.

(iv) Since V, ϵ, I and $\mathcal{E}$ are arbitrary, 493D tells us that $S(\mathfrak{A})$ is an extremely amenable group, at least when $(\mathfrak{A},\bar\mu)$ is an atomless probability algebra.

(b) The rest of the argument is straightforward, as in 493E. First, $S(\mathfrak{A})$ is extremely amenable whenever $(\mathfrak{A},\bar\mu)$ is an atomless totally finite measure algebra. For a general atomless measure algebra $(\mathfrak{A},\bar\mu)$, set $\mathfrak{A}^f = \{c : \bar\mu c < \infty\}$. For each $c \in \mathfrak{A}^f$, let $\mathfrak{A}_c$ be the corresponding principal ideal of $\mathfrak{A}$. Then we can identify $S(\mathfrak{A}_c)$, as topological group, with the linear subspace of $L^0(\mathfrak{A})$ generated by $\{\chi a : a \in \mathfrak{A}_c\}$, and it is extremely amenable. Since $\{S(\mathfrak{A}_c) : c \in \mathfrak{A}^f\}$ is an upwards-directed family of extremely amenable subgroups of $L^0(\mathfrak{A})$ with dense union in $L^0(\mathfrak{A})$, $L^0(\mathfrak{A})$ itself is extremely amenable, by 493Bb, as before.

493G I take the proof of the next theorem in two parts, the first being the leading special case.

Lemma Let κ be an infinite cardinal, λ the usual measure on $\{0,1\}^\kappa$ and $(\mathfrak{B},\bar\lambda)$ its measure algebra with its measure metric. Let $\mathrm{Aut}_{\bar\lambda}\mathfrak{B}$ be the group of measure-preserving automorphisms of $\mathfrak{B}$ with the topology $\mathfrak{T}$ of pointwise convergence inherited from the isometry group of $\mathfrak{B}$ (441G). Then $\mathrm{Aut}_{\bar\lambda}\mathfrak{B}$ is extremely amenable.

proof (a) For each $I \in [\kappa]^{<\omega}$, let H_I be the group of bijections from $\{0,1\}^I$ to itself. For $q \in H_I$ let $f_q : \{0,1\}^\kappa \to \{0,1\}^\kappa$ be the measure space automorphism defined by saying that

$$f_q(x)\restriction\kappa\setminus I = x\restriction\kappa\setminus I, \quad f_q(x)\restriction I = q(x\restriction I)$$

for every $x \in \{0,1\}^\kappa$, and ψ_q the member of $\mathrm{Aut}_{\bar\lambda}\mathfrak{B}$ defined by the formula

$$\psi_q(E^\bullet) = f_q[E]^\bullet \text{ for every measurable } E \subseteq \{0,1\}^\kappa.$$

Note that $f_{qq'} = f_q f_{q'}$ for all q, $q' \in H_I$, so that $q \mapsto \psi_q : H_I \to \mathrm{Aut}_{\bar\lambda}\mathfrak{B}$ is a group homomorphism. Set $G_I = \{\psi_q : q \in H_I\}$, so that G_I is a subgroup of $\mathrm{Aut}_{\bar\lambda}\mathfrak{B}$.

If $I \subseteq J \in [\kappa]^{<\omega}$ then $G_I \subseteq G_J$. **P** For any $q \in H_I$ we can define $q' \in H_J$ by setting

$$q'(z)\restriction J\setminus I = z\restriction J\setminus I, \quad q'(z)\restriction I = q(z\restriction I)$$

for every $z \in \{0,1\}^J$; then $f_{q'} = f_q$ so $\psi_{q'} = \psi_q$. As q is arbitrary, $G_I \subseteq G_J$. $\blacksquare$

Set $G = \bigcup\{G_I : I \in [\kappa]^{<\omega}\}$, so that G is a subgroup of $\mathrm{Aut}_{\bar\lambda}\mathfrak{B}$.

(b) Let V be a neighbourhood of the identity of G (with the subspace topology inherited from $\mathrm{Aut}_{\bar\lambda}\mathfrak{B}$), $\epsilon > 0$ and $K \subseteq G$ a finite set. Then there is a (purely atomic) Borel probability measure ν on G such that

(i) $\nu(\pi B) = \nu B$ for every $B \subseteq G$ and every $\pi \in K$,

(ii) $\nu(VB \cap G) \geq 1 - \epsilon$ whenever $B \subseteq G$ and $\nu B \geq \frac{1}{2}$.

P There are a finite set $A \subseteq \mathfrak{B}$ and a $\delta > 0$ such that $\pi \in V$ whenever $\pi \in G$ and $\bar\lambda(a \triangle \pi a) \leq \delta$ for every $a \in A$. Let $I \in [\kappa]^{<\omega}$ be such that $K \subseteq G_I$ and $2^n\delta - 1 \geq \sqrt{2^{n+6}\ln\frac{1}{\epsilon}}$, where $n = \#(I)$. (This is where we need to know that κ is infinite.) Let ν be the Borel probability measure on G such that $\nu\{\psi_q\} = 1/(2^n)!$ for every $q \in H_I$. Since ν acts on G_I as its Haar probability measure,

$$\nu(\pi B) = \nu(G_I \cap \pi B) = \nu(\pi(G_I \cap B)) = \nu(G_I \cap B) = \nu B$$

for every $B \subseteq G$ and every $\pi \in K \subseteq G_I$.

Now suppose that $B \subseteq G$ and $\nu B \geq \frac{1}{2}$. Set $C = \{q : q \in H_I, \psi_q \in B\}$, so that $\#(C) \geq \frac{1}{2}\#(H_I) = \frac{1}{2}(2^n)!$. Set $r = \lfloor 2^n\delta \rfloor$, so that $\exp(-r^2/2^{n+6}) \leq \epsilon$. Let $\tilde C$ be the set of those $\tilde q \in H_I$ such that there is some $q \in C$ with $\#(\{z : z \in \{0,1\}^I, \tilde q(z) \neq q(z)\}) \leq r$; then

$$\#(\tilde C) \geq (1 - \exp(-r^2/2^{n+6}))(2^n)! \geq (1-\epsilon)(2^n)!$$

by 492I. Writing $B' = \{\psi_q : q \in \tilde C\}$, $\nu B' \geq 1 - \epsilon$. Now if $\pi \in B'$, there are $\tilde q \in \tilde C$, $q \in C$ such that $\pi = \psi_{\tilde q}$ and $\#(\{z : z \in \{0,1\}^I, \tilde q(z) \neq q(z)\}) \leq r$. But this means that $\psi_q \in B$, while

$$\#(\{z : q^{-1}(z) \neq \tilde q^{-1}(z)\}) = \#(\{z : \tilde q q^{-1}(z) \neq q q^{-1}(z)\}) = \#(\{z : \tilde q(z) \neq q(z)\}) \leq r.$$

Setting

$$E_0 = \{x : x \in \{0,1\}^\kappa, \tilde q^{-1}(x\restriction I) \neq q^{-1}(x\restriction I)\},$$

we see that $\lambda E_0 \leq 2^{-n}r \leq \delta$ and $f_q^{-1}(x) = f_{\tilde q}^{-1}(x)$ for every $x \in \{0,1\}^\kappa \setminus E_0$, so that $f_q[E] \triangle f_{\tilde q}[E] \subseteq E_0$ for every $E \subseteq \{0,1\}^\kappa$. Accordingly $\pi a \triangle \psi_q a \subseteq E_0^\bullet$ for every $a \in \mathfrak{B}$, and

$$\bar\lambda(a \triangle \pi\psi_{q^{-1}}a) = \bar\lambda(\pi(\psi_{q^{-1}}a) \triangle \psi_q(\psi_{q^{-1}}a)) \leq \bar\lambda E_0^\bullet \leq \delta$$

for every $a \in A$. This shows that $\pi\psi_q^{-1} \in V$ so that $\pi \in VB$. As π is arbitrary, $B' \subseteq VB$ and $\nu(G \cap VB) \geq \nu B' \geq 1 - \epsilon$. As B is arbitrary, ν satisfies the condition (ii). **Q**

(c) By 493D, G is extremely amenable. Now G is dense in $\mathrm{Aut}_{\bar\lambda}\mathfrak{B}$. **P** Take any $\pi \in \mathrm{Aut}_{\bar\lambda}\mathfrak{B}$ and any neighbourhood V of π in $\mathrm{Aut}_{\bar\lambda}\mathfrak{B}$. Then there are $a_0, \ldots, a_k \in \mathfrak{B}$ and $\epsilon > 0$ such that

$$V' = \{\psi : \psi \in \mathrm{Aut}_{\bar\lambda}\mathfrak{B}, \bar\lambda(\psi a_i \triangle \pi a_i) \leq \epsilon \text{ for every } i \leq k\}$$

is included in V. Let $b_0, \ldots, b_m$ be the atoms of the finite subalgebra of $\mathfrak{B}$ generated by $\{a_i : i \leq k\} \cup \{\pi a_i : i \leq k\}$. Set $\delta = \epsilon/12(m+1)(2m+1) > 0$. For $j \leq m$, let $E_j, F_j \subseteq \{0,1\}^\kappa$ be such that $E_j^\bullet = b_j$ and $F_j^\bullet = \pi b_j$; let E_j', F_j' be open-and-closed sets such that $\lambda(E \triangle E_j') + \lambda(F_j \triangle F_j') \leq \delta$. Let $I \subseteq \kappa$ be a finite set such that E_j' and F_j' are determined by coordinates in I for every $j \leq m$. For each $j \leq m$, set $E_j'' = E_j' \setminus \bigcup_{i<j} E_i'$ and $F_j'' = F_j' \setminus \bigcup_{i<j} F_i'$, so that E_j'' and F_j'' are still determined by coordinates in I; finally, let $\tilde E_j \subseteq E_j''$ and $\tilde F_j \subseteq F_j''$ be sets determined by coordinates in I such that $\lambda\tilde E_j = \lambda\tilde F_j = \min(\lambda E_j'', \lambda F_j'')$.

For each $j \leq m$, we have $\lambda(E_j \triangle E_j') \leq \delta$; since $\lambda(E_i \cap E_j) = 0$ if $i < j$, $\lambda(E_i' \cap E_j') \leq 2\delta$ if $i < j$, and $\lambda(E_j' \setminus E_j'') \leq 2m\delta$; accordingly $\lambda(E_j \triangle E_j'') \leq (2m+1)\delta$, for every $j \leq m$. Similarly $\lambda(F_j \triangle F_j'') \leq (2m+1)\delta$; because $\lambda E_j = \lambda F_j$,

$$\lambda(E_j'' \setminus \tilde E_j) \leq |\lambda E_j'' - \lambda F_j''| \leq 4(m+1)\delta, \quad \lambda(E_j \triangle \tilde E_j) \leq 6(m+1)\delta$$

for each j. Similarly $\lambda(F_j \triangle \tilde F_j) \leq 6(m+1)\delta$ for each j.

Because $\tilde E_j$ is determined by coordinates in I, it is of the form $\{x : x\restriction I \in C_j\}$ for some $C_j \subseteq \{0,1\}^I$. Because $\tilde E_0, \ldots, \tilde E_m$ are disjoint, so are $C_0, \ldots, C_m$. Similarly, $\tilde F_j$ can be expressed as $\{x : x\restriction I \in D_j\}$ where $D_0, \ldots, D_m \subseteq \{0,1\}^I$ are disjoint. Because $\lambda\tilde E_j = \lambda\tilde F_j$, $\#(C_j) = \#(D_j)$ for each j. There is therefore a $q \in H_I$ such that $q[C_j] = D_j$ for each j. Now $\psi_q\tilde E_j^\bullet = \tilde F_j^\bullet$, so

$$\begin{aligned}\bar\lambda(\psi_q b_j \triangle \pi b_j) &\leq \bar\lambda(\psi_q b_j \triangle \tilde F_j^\bullet) + \bar\lambda(\tilde F_j^\bullet \triangle F_j^\bullet)\\ &= \bar\lambda(b_j \triangle \tilde E_j^\bullet) + \lambda(\tilde F_j \triangle F_j)\\ &\leq \lambda(E_j \triangle \tilde E_j) + 6(2m+1)\delta \leq 12(2m+1)\delta\end{aligned}$$

for each j. Since every a_i is a union of some of the b_j,

$$\bar\lambda(\psi_q a_i \triangle \pi a_i) \leq 12(2m+1)(m+1)\delta = \epsilon$$

for every $i \leq k$, and $\psi_q \in V' \subseteq V$. Thus $G \cap V \neq \emptyset$; as V is arbitrary, G is dense in $\mathrm{Aut}_{\bar\lambda}\mathfrak{B}$. **Q**

(d) By 493Bb, with $\mathcal{H} = \{G\}$, $\mathrm{Aut}_{\bar\lambda}\mathfrak{B}$ is extremely amenable.

493H Theorem (Giordano & Pestov 02) Let $(\mathfrak{A}, \bar\mu)$ be an atomless measure algebra, and set $\mathfrak{A}^f = \{a : \bar\mu a < \infty\}$. Let $\mathrm{Aut}_{\bar\mu}\mathfrak{A}$ be the group of measure-preserving automorphisms of $\mathfrak{A}$. For π, $\phi \in \mathrm{Aut}_{\bar\mu}\mathfrak{A}$ and $c \in \mathfrak{A}^f$, set $\sigma_c(\pi,\phi) = \bar\mu(\pi c \triangle \phi c)$. Then $\{\sigma_c : c \in \mathfrak{A}^f\}$ is a family of pseudometrics on $\mathrm{Aut}_{\bar\mu}\mathfrak{A}$. Under the topology it induces, $\mathrm{Aut}_{\bar\mu}\mathfrak{A}$ is an extremely amenable topological group.

proof (a) It is elementary to check that every σ_c is a pseudometric. To see that the topology $\mathfrak{T}$ generated by these pseudometrics is compatible with the group structure, recall that $(a,b) \mapsto \bar\mu(a \triangle b)$ is a metric on $\mathfrak{A}^f$ (323Ae). Now if we set $\theta(\pi) = \pi\restriction\mathfrak{A}^f$, then θ is a group homomorphism from $\mathrm{Aut}_{\bar\mu}\mathfrak{A}$ to the isometry group $\mathrm{Isom}(\mathfrak{A}^f)$ of $\mathfrak{A}^f$, and $\mathfrak{T}$ is just $\{\theta^{-1}[V] : V \in \mathfrak{S}\}$, where $\mathfrak{S}$ is the topology of pointwise convergence in $\mathrm{Isom}(\mathfrak{A}^f)$. Since $(\mathrm{Isom}(\mathfrak{A}^f), \mathfrak{S})$ is a topological group (441Ga), so is $(\mathrm{Aut}_{\bar\mu}\mathfrak{A}, \mathfrak{T})$.

(b) For $a \in \mathfrak{A}$ write $\mathfrak{A}_a$ for the principal ideal of $\mathfrak{A}$ generated by a and G_a for the subgroup of those $\pi \in \mathrm{Aut}_{\bar\mu}\mathfrak{A}$ which are supported by a (definition: 381Ba), so that G_a is isomorphic (as topological group) to the group of measure-preserving automorphisms of $\mathfrak{A}_a$.

(c) Let A be the set of those $a \in \mathfrak{A}^f$ such that $\mathfrak{A}_a$ is homogeneous. Then G_a is extremely amenable for every $a \in A$. **P** If $a = 0$ this is trivial, since G_a has just one element. Otherwise, $\mathfrak{A}_a$ is isomorphic, up to a scalar multiple of the measure, to the measure algebra $\mathfrak{B}$ of the usual measure λ on $\{0,1\}^\kappa$ where κ is infinite, by Maharam's theorem (331L). So G_a is isomorphic, as topological group, to $\mathrm{Aut}_{\bar\lambda}\mathfrak{B}$, which is extremely amenable, by 493G. **Q**

(d) Set $I = \{a_0 \cup \ldots \cup a_n : a_0, \ldots, a_n \in A\}$. Then G_b is extremely amenable for every $b \in I$. **P** Since $\mathfrak{A}_{a\cup b}$ is homogeneous whenever $\mathfrak{A}_a$, $\mathfrak{A}_b$ are homogeneous and of the same infinite Maharam type, we can express b as $a_0 \cup \ldots \cup a_n$ where all the $\mathfrak{A}_{a_i}$ are homogeneous and have different Maharam types. (This is really where I use the hypothesis that $\mathfrak{A}$ is atomless.) In this case, G_b will be isomorphic (as topological group) to $\prod_{i=0}^k G_{a_i}$, so is extremely amenable (493Bd). **Q**

Note that as $\pi a \in A$ whenever $a \in A$ and $\pi \in \mathrm{Aut}_{\bar\mu}\mathfrak{A}$, $\pi b \in I$ whenever $b \in I$ and $\pi \in \mathrm{Aut}_{\bar\mu}\mathfrak{A}$. Also $a' \in A$ whenever $a \in A$ and $a' \subseteq a$, so I is an ideal of $\mathfrak{A}$.

(e) Set $G = \bigcup_{b\in I} G_b$. Then G is dense in $\mathrm{Aut}_{\bar\mu}\mathfrak{A}$. **P** Suppose that $\pi \in \mathrm{Aut}_{\bar\mu}\mathfrak{A}$, $a_0, \ldots, a_n \in \mathfrak{A}^f$ and $\epsilon > 0$. Set $c = \sup_{i\leq n} a_i$. By 332A, there is a $b_0 \in I$ such that $b_0 \subseteq c$ and $\bar\mu(c \setminus b_0) \leq \frac{1}{2}\epsilon$. Set $b = b_0 \cup \pi b_0 \in I$. Then there is a $\phi \in G_b$ such that $\phi d = \pi d$ for every $d \subseteq b_0$ (332L). Now

$$\phi a_i \triangle \pi a_i \subseteq \phi(a_i \setminus b_0) \cup \pi(a_i \setminus b_0)$$

has measure at most $2\bar\mu(c \setminus b_0) \leq \epsilon$ for every $i \leq n$. As π, $a_0, \ldots, a_n$ and ϵ are arbitrary, G is dense in $\mathrm{Aut}_{\bar\mu}\mathfrak{A}$. **Q**

(f) Thus $\{G_b : b \in I\}$ is an upwards-directed family of extremely amenable subgroups of $\mathrm{Aut}_{\bar\mu}\mathfrak{A}$ with dense union. By 493Bb, $\mathrm{Aut}_{\bar\mu}\mathfrak{A}$ is extremely amenable.

493I Returning to the ideas of §476, we find another remarkable example of an extremely amenable topological group. I recall the notation of 476M. Let X be a (real) inner product space. S_X will be the unit sphere $\{x : x \in X, \|x\| = 1\}$. Let H_X be the isometry group of S_X with its topology of pointwise convergence. When X is finite-dimensional, it is isomorphic, as inner product space, to $\mathbb{R}^r$, where $r = \dim X$. In this case S_X is compact, so (if $r \geq 1$) has a unique H_X-invariant Radon probability measure ν_X, which is

strictly positive, and is a multiple of $(r-1)$-dimensional Hausdorff measure; also H_X is compact (441Gb), so has a unique Haar probability measure λ_X.

Lemma For any $m \in \mathbb{N}$ and any $\epsilon > 0$, there is an $r(m,\epsilon) \geq \max(2,m)$ such that whenever X is a finite-dimensional inner product space of dimension at least $r(m,\epsilon)$, $x_0, \ldots, x_{m-1} \in S_X$, Q_1, $Q_2 \subseteq H_X$ are closed sets and $\min(\lambda_X Q_1, \lambda_X Q_2) \geq \epsilon$, then there are $f_1 \in Q_1$, $f_2 \in Q_2$ such that $\|f_1(x_i) - f_2(x_i)\| \leq \epsilon$ for every $i < m$.

proof Induce on m. For $m = 0$, the result is trivial. For the inductive step to $m+1$, take $r(m+1,\epsilon) > r(m, \frac{1}{3}\epsilon)$ such that whenever $r(m+1,\epsilon) \leq \dim X < \omega$ and A_1, $A_2 \subseteq S_X$ and $\min(\nu_X^* A_1, \nu_X^* A_2) \geq \frac{1}{2}\epsilon$ then there are $x \in A_1$, $y \in A_2$ such that $\|x - y\| \leq \frac{1}{3}\epsilon$; this is possible by 476P.

Now take any inner product space X of finite dimension $r \geq r(m+1,\epsilon)$, closed sets Q_1, $Q_2 \subseteq H_X$ such that $\min(\lambda_X Q_1, \lambda_X Q_2) \geq \epsilon$, and orthonormal $x_0, \ldots, x_m \in S_X$. Let Y be the $(r-1)$-dimensional subspace $\{x : x \in X, (x|x_m) = 0\}$, so that $\dim Y \geq r(m, \frac{1}{3}\epsilon)$, and for $i < m$ let $y_i \in Y$ be a unit vector such that x_i is a linear combination of y_i and x_m. Set $H'_Y = \{f : f \in H_X, f(x_m) = x_m\}$; then $f \mapsto f{\restriction}S_Y$ is a topological group isomorphism from H'_Y to H_Y. **P** (i) If $f \in H'_Y$ and $x \in S_X$, then

$$x \in S_Y \iff (x|x_m) = 0 \iff (f(x)|f(x_m)) = 0 \iff f(x) \in S_Y,$$

so $f{\restriction}S_Y$ is a bijection from S_Y to itself and belongs to H_Y. (ii) If $g \in H_Y$, we can define $f \in H'_Y$ by setting $f(\alpha x + \beta x_m) = \alpha g(x) + \beta x_m$ whenever $x \in S_Y$ and $\alpha^2 + \beta^2 = 1$, and $f{\restriction}S_Y = g$. (iii) Note that H'_Y is a closed subgroup of H_X, so in itself is a compact Hausdorff topological group. Since the map $f \mapsto f{\restriction}S_Y : H'_Y \to H_Y$ is a bijective continuous group homomorphism between compact Hausdorff topological groups, it is a topological group isomorphism. **Q**

Let λ'_Y be the Haar probability measure of H'_Y. Then $\lambda_X Q_1 = \int \lambda'_Y(H'_Y \cap f^{-1}Q_1)\lambda_X(df)$ (443Te), so $\lambda'_X Q_1 \geq \frac{1}{2}\epsilon$, where $Q'_1 = \{f : \lambda'_Y(H'_Y \cap f^{-1}Q_1) \geq \frac{1}{2}\epsilon\}$. Similarly, setting $Q'_2 = \{f : \lambda'_Y(H'_Y \cap f^{-1}Q_2) \geq \frac{1}{2}\epsilon\}$, $\lambda_X Q'_2 \geq \frac{1}{2}\epsilon$. Next, setting $\theta(f) = f(x_m)$ for $f \in H_X$, $\lambda_X\theta^{-1}$ is an X-invariant Radon probability measure on S_X (443Ta), so must be equal to ν_X. Accordingly

$$\nu_X(\theta[Q'_j]) = \lambda_X(\theta^{-1}[\theta[Q'_j]]) \geq \lambda_X Q'_j \geq \frac{1}{2}\epsilon$$

for both j.

We chose $r(m+1,\epsilon)$ so large that we can be sure that there are $z_1 \in \theta[Q'_1]$, $z_2 \in \theta[Q'_2]$ such that $\|z_1 - z_2\| \leq \frac{1}{3}\epsilon$. Let $h_1 \in Q'_1$, $h_2 \in Q'_2$ be such that $h_1(x_m) = \theta(h_1) = z_1$ and $h_2(x_m) = z_2$. Let $h \in H_X$ be such that $h(z_1) = z_2$ and $\|h(x) - x\| \leq \frac{1}{3}\epsilon$ for every $x \in S_X$ (4A4Jf). Set $\tilde{h}_2 = hh_1$, so that $\tilde{h}_2(x_m) = z_2$ and $\|h_1(x) - \tilde{h}_2(x)\| \leq \frac{1}{3}\epsilon$ for every $x \in S_X$. Note that $\tilde{h}_2^{-1}h_2 \in H'_Y$, so that $\tilde{h}_2$ and h_2 belong to the same left coset of H'_Y, and

$$\lambda'_Y(H'_Y \cap \tilde{h}_2^{-1}Q_2) = \lambda'_Y(H'_Y \cap h_2^{-1}Q_2) \geq \frac{1}{2}\epsilon$$

by 443Pa.

At this point, recall that $\dim Y \geq r(m, \frac{1}{3}\epsilon)$, and that λ'_Y is a copy of λ_Y. So we have $g_1 \in H'_Y \cap h_1^{-1}Q_1$, $g_2 \in H'_Y \cap \tilde{h}_2^{-1}Q_2$ such that $\|g_1(y_i) - g_2(y_i)\| \leq \frac{1}{3}\epsilon$ for every $i < m$. We have $f_1 = h_1 g_1 \in Q_1$ and $f_2 = \tilde{h}_2 g_2 \in Q_2$. For any $i < m$,

$$\begin{aligned}\|f_1(y_i) - f_2(y_i)\| &\leq \|h_1 g_1(y_i) - h_1 g_2(y_i)\| + \|h_1 g_2(y_i) - \tilde{h}_2 g_2(y_i)\| \\ &\leq \|g_1(y_i) - g_2(y_i)\| + \tfrac{1}{3}\epsilon \leq \tfrac{2}{3}\epsilon.\end{aligned}$$

Also $g_1(x_m) = g_2(x_m) = x_m$, so

$$\|f_1(x_m) - f_2(x_m)\| = \|h_1(x_m) - \tilde{h}_2(x_m)\| \leq \tfrac{1}{3}\epsilon.$$

If $i < m$, then $x_i = (x_i|x_m)x_m + (x_i|y_i)y_i$, so $f_j(x_i) = (x_i|x_m)f_j(x_m) + (x_i|y_i)f_j(y_i)$ for both j (476N) and

$$\|f_1(x_i) - f_2(x_i)\| \leq \tfrac{1}{3}\epsilon|(x_i|x_m)| + \tfrac{2}{3}\epsilon|(x_i|y_i)|$$
$$\leq \sqrt{(\tfrac{1}{3}\epsilon)^2 + (\tfrac{2}{3}\epsilon)^2}\sqrt{(x_i|x_m)^2 + (x_i|y_i)^2} \leq \epsilon.$$

So f_1 and f_2 witness that the induction proceeds.

493J Theorem Let X be an infinite-dimensional inner product space. Then the isometry group H_X of its unit sphere S_X, with its topology of pointwise convergence, is extremely amenable.

proof I use the same approach as in 493G.

(a) Let $\mathcal{Y}$ be the family of finite-dimensional subspaces of X. For $Y \in \mathcal{Y}$, write $Y^\perp$ for the orthogonal complement of Y, so that $X = Y \oplus Y^\perp$ (4A4Je). For $q \in H_Y$ define $\theta_Y(q) : S_X \to S_X$ by saying that $\theta_Y(q)(\alpha y + \beta z) = \alpha q(y) + \beta z$ whenever $y \in S_Y$, $z \in S_{Y^\perp}$ and $\alpha^2 + \beta^2 = 1$. Then $\theta_Y : H_Y \to H_X$ is a injective group homomorphism. Also it is continuous, because $q \mapsto \alpha q(y) + \beta z$ is continuous for all relevant α, β, y and z.

If Y, $W \in \mathcal{Y}$ and $Y \subseteq W$ then $\theta_Y[H_Y] \subseteq \theta_W[H_W]$. **P** For any $q \in H_Y$ we can define $q' \in H_W$ by saying that $q'(\alpha y + \beta x) = \alpha q(y) + \beta x$ whenever $y \in S_Y$, $x \in S_{W \cap Y^\perp}$ and $\alpha^2 + \beta^2 = 1$. Now $\theta_Y(q) = \theta_W(q') \in \theta_W[H_W]$. **Q**

Set $G^* = \bigcup_{Y \in \mathcal{Y}} \theta_Y[H_Y]$, so that G^* is a subgroup of H_X.

(b) Let V be an open neighbourhood of the identity in G^* (with the subspace topology inherited from the topology of pointwise convergence on H_X), $\epsilon > 0$ and $I \subseteq G^*$ a finite set. Then there is a Borel probability measure λ on G^* such that

(i) $\lambda(fQ) = \lambda Q$ for every $f \in I$ and every closed set $Q \subseteq G^*$,

(ii) $\lambda(VQ) \geq 1 - \epsilon$ whenever $Q \subseteq G^*$ is closed and $\lambda Q \geq \frac{1}{2}$.

P We may suppose that $\epsilon \leq \frac{1}{2}$. Let $J \in [S_X]^{<\omega}$ and $\delta > 0$ be such that $f \in V$ whenever $f \in G^*$ and $\|f(x) - x\| \leq \delta$ for every $x \in J$. We may suppose that J is non-empty; set $m = \#(J)$. Let $Y \in \mathcal{Y}$ be such that $J \subseteq Y$ and $I \subseteq \theta_Y[H_Y]$ and $\dim Y = r \geq r(m, \epsilon)$, as chosen in 493I. (This is where we need to know that X is infinite-dimensional.) Set $\lambda F = \lambda_Y \theta_Y^{-1}[F]$ for every Borel set $F \subseteq G^*$.

If $f \in I$ and $F \subseteq G^*$ is closed, then

$$\lambda(fF) = \lambda_Y \theta_Y^{-1}[fF] = \lambda_Y(\theta_Y^{-1}(f)\theta_Y^{-1}[F]) = \lambda_Y \theta_Y^{-1}[F] = \lambda F.$$

So λ satisfies condition (i).

? Suppose, if possible, that $Q_1 \subseteq G^*$ is a closed set such that $\lambda Q_1 \geq \frac{1}{2}$ and $\lambda(VQ_1) < 1 - \epsilon$; set $Q_2 = G^* \setminus VQ_1$. Then $\theta_Y^{-1}[Q_1]$ and $\theta_Y^{-1}[Q_2]$ are subsets of H_Y both of measure at least ϵ. Set $R_j = \{q : q \in H_Y, q^{-1} \in \theta_Y^{-1}[Q_j]\}$ for each j; because H_Y is compact, therefore unimodular,

$$\lambda_Y R_j = \lambda_Y \theta_Y^{-1}[Q_j] = \lambda Q_j \geq \epsilon$$

for both j. Because $\dim Y \geq r(m, \epsilon)$, there are $q_1 \in R_1$, $q_2 \in R_2$ such that $\|q_1(x) - q_2(x)\| \leq \epsilon$ for $x \in J$. Set $f = \theta_Y(q_2^{-1}q_1)$. If $x \in J$, then

$$\|f(x) - x\| = \|q_2^{-1}q_1(x) - x\| = \|q_1(x) - q_2(x)\| \leq \epsilon.$$

As this is true for every $x \in J$, $f \in V$. On the other hand, $\theta_Y(q_1^{-1}) \in Q_1$ and $\theta_Y(q_2^{-1}) \in Q_2$ and $f\theta_Y(q_1^{-1}) = \theta_Y(q_2^{-1})$, so $\theta_Y(q_2^{-1}) \in VQ_1 \cap Q_2$, which is impossible. **X**

Thus λ satisfies (ii). **Q**

(c) By 493D, G^* is extremely amenable. But G^* is dense in H_X. **P** If $f \in H_X$ and $I \subseteq S_X$ is finite and not empty, let Y_1 be the linear subspace of X generated by I, and let $(y_1, \ldots, y_m)$ be an orthonormal basis of Y_1. Set $z_j = f(y_j)$ for each j, so that $(z_1, \ldots, z_m)$ is orthonormal (476N); let Y be the linear subspace of X generated by $y_1, \ldots, y_m, z_1, \ldots, z_m$. Set $r = \dim Y$ and extend the orthonormal sets $(y_1, \ldots, y_m)$ and $(z_1, \ldots, z_m)$ to orthonormal bases $(y_1, \ldots, y_r)$ and $(z_1, \ldots, z_r)$ of Y. Then we have an isometric linear operator $T : Y \to Y$ defined by saying that $Ty_i = z_i$ for each i; set $q = T \upharpoonright S_Y \in H_Y$. By 476N, $q(x) = f(x)$ for every $x \in I$, so $\theta_Y(q)$ agrees with f on I, while $\theta_Y(q) \in G^*$. As f and I are arbitrary, G^* is dense in G. **Q**

So 493Bb tells us that H_X is extremely amenable, and the proof is complete.

493K The following result shows why extremely amenable groups did not appear in Chapter 44.

Theorem (VEECH 77) If G is a locally compact Hausdorff topological group with more than one element, it is not extremely amenable.

proof If G is compact, this is trivial, since the left action of G on itself has no fixed point; so let us assume henceforth that G is not compact.

(a) Let Z be the greatest ambit of G, $a \mapsto \hat{a} : G \to Z$ the canonical map, and U the space of bounded right-uniformly continuous real-valued functions on G. (I aim to show that the action of G on Z has no fixed point.) Take any $z^* \in Z$. Let V_0 be a compact neighbourhood of the identity e in G, and let $B_0 \subseteq G$ be a maximal set such that $V_0 b \cap V_0 c = \emptyset$ for all distinct b, $c \in B_0$. Then for any $a \in G$ there is a $b \in B_0$ such that $V_0 a \cap V_0 b \neq \emptyset$, that is, $a \in V_0^{-1} V_0 B_0$. So if we set $Y_0 = \overline{\{\hat{b} : b \in B\}} \subseteq Z$, $\{a \bullet y : a \in V_0^{-1}V_0,\ y \in Y_0\}$ is a compact subset of Z including $\{\hat{a} : a \in G\}$, and is therefore the whole of Z (449Dc). Let $a_0 \in V_0^{-1}V_0$, $y_0 \in Y_0$ be such that $a_0 \bullet y_0 = z^*$, and set $B_1 = a_0 B_0$, $V_1 = a_0 V_0 a_0^{-1}$; then $z^* \in \overline{\{\hat{b} : b \in B_1\}}$ and $V_1 b \cap V_1 c = \emptyset$ for all distinct b, $c \in B_1$.

(b) Because V_1 is compact and G is not compact, there is an $a_1 \in G \setminus V_1$. Let $V_2 \subseteq V_1$ be a neighbourhood of e such that $a_1^{-1} V_2 V_2^{-1} a_1 \subseteq V_1$. Then we can express B_1 as $D_0 \cup D_1 \cup D_2$ where $a_1 D_i \cap V_2 D_i = \emptyset$ for all i. **P** Consider $\{(b, c) : b,\ c \in B_1,\ a_1 b \in V_2 c\}$. Because $V_2 c \cap V_2 c' \subseteq V_1 c \cap V_1 c' = \emptyset$ for all distinct c, $c' \in B_1$, this is the graph of a function $h : D \to B_1$ for some $D \subseteq B_1$. **?** If h is not injective, we have distinct b, $c \in B_1$ and $d \in B_1$ such that $a_1 b$ and $a_1 c$ both belong to $V_2 d$. But in this case b and c both belong to $a_1^{-1} V_2 d$ and $bc^{-1} \in a_1^{-1} V_2 d d^{-1} V_2^{-1} a_1 \subseteq V_1$ and $b \in V_1 c$, which is impossible. **X** At the same time, if $b \in B_1$, then $a_1 b \notin V_2 b$ because $a_1 \notin V_2$, so $h(b) \neq b$ for every $b \in D$.

Let $D_0 \subseteq D$ be a maximal set such that $h[D_0] \cap D_0 = \emptyset$, and set $D_1 = h[D_0]$, $D_2 = B_1 \setminus (D_0 \cup D_1)$. Then $h[D_0] \cap D_0 = \emptyset$ by the choice of D_0; $h[D \cap D_1] \cap D_1 = \emptyset$ because h is injective and $D_1 \subseteq h[D \setminus D_1]$; and $h[D \cap D_2] \subseteq D_0$ because if $b \in D \cap D_2$ there must have been some reason why we did not put b into D_0, and it wasn't because $b \in h[D_0]$ or because $h(b) = b$. So $h[D_i] \cap D_i = \emptyset$ for all i, which is what was required. **Q**

(c) Since $z^* \in \overline{\{\hat{b} : b \in B_1\}}$, there must be some $j \leq 2$ such that $z^* \in \overline{\{\hat{b} : b \in D_j\}}$. Now recall that the right uniformity on G, like any uniformity, can be defined by some family of pseudometrics (4A2Ja). There is therefore a pseudometric ρ on G such that $W_\epsilon = \{(a, b) : a,\ b \in G,\ \rho(a, b) \leq \epsilon\}$ is a member of the right uniformity on G for every $\epsilon > 0$ and $W_1 \subseteq \{(a, b) : ab^{-1} \subseteq V_2\}$. If now we set

$$f(a) = \min(1, \rho(a, D_j)) = \min(1, \inf\{\rho(a, b) : b \in D_j\})$$

for $a \in G$, $f : G \to \mathbb{R}$ is bounded and uniformly continuous for the right uniformity, so belongs to U. On the other hand, if b, $c \in D_j$, then $a_1 b \notin V_2 c$, that is, $a_1 b c^{-1} \notin V_2$ and $\rho(a_1 b, c) > 1$; as c is arbitrary, $f(a_1 b) = 1$.

(d) Now $\hat{b}(f) = f(b) = 0$ for every $b \in D_j$, so $z^*(f) = 0$. On the other hand, because $z \mapsto a_1 \bullet z$ is continuous,

$$a_1 \bullet z^* \in \overline{\{a_1 \bullet \hat{b} : b \in D_j\}} = \overline{\{\widehat{a_1 b} : b \in D_j\}},$$

so

$$(a_1 \bullet z^*)(f) \geq \inf_{b \in D_j} \widehat{a_1 b}(f) = \inf_{b \in D_j} f(a_1 b) = 1,$$

so $a_1 \bullet z^* \neq z^*$. As z^* is arbitrary, this shows that the action of G on Z has no fixed point, and G is not extremely amenable.

493X Basic exercises (a) Show that a dense subgroup of an extremely amenable topological group is extremely amenable.

(b) Let G be a Hausdorff topological group, and $\widehat{G}$ its completion with respect to its bilateral uniformity. Show that G is extremely amenable iff $\widehat{G}$ is.

>(c) Let X be a set with more than one member and ρ the metric on X such that $\rho(x, y) = 1$ for all distinct x, $y \in X$. Let G be the isometry group of X with the topology of pointwise convergence. Show that G is not extremely amenable. (*Hint*: give X a total ordering $\leq$, and let x, y be any two points of X.

For $a \in G$ set $f(a) = 1$ if $a^{-1}(x) < a^{-1}(y)$, -1 otherwise. Show that, in the language of 449D, $f \in U$. Show that if $(\overleftarrow{x\,y})$ is the transposition exchanging x and y then $(\overleftarrow{x\,y})\bullet f = -f$, while $|z(f)| = 1$ for every z in the greatest ambit of G.) (Compare 449Xc.)

(d) Show that under the conditions of 493D (i) there is a finitely additive functional $\nu : \mathcal{B} \to [0,1]$ such that $\nu(aF) = \nu F$ for every $a \in G$ and every zero set $F \subseteq G$, while $\nu(VF) = 1$ whenever V is a neighbourhood of the identity, F is a zero set and $\nu F > \frac{1}{2}$ (ii) there is a positive linear functional $p : C_b(G) \to \mathbb{R}$ such that $p(a\bullet f) = p(f)$ for every $f \in C_b(G)$ and $a \in G$.

(e) Let $(\mathfrak{A}, \bar{\mu})$ be a σ-finite measure algebra of countable Maharam type. Show that $\mathrm{Aut}_{\bar{\mu}}\mathfrak{A}$, with the topology described in 493H, is a Polish group. (*Hint*: 441Xm.)

(f) Let X be any inner product space. Show that the isometry group of X, with its topology of pointwise convergence, is amenable. (*Hint*: 449Cd.)

(g) Let X be a separable Hilbert space. Show that the isometry group of its unit sphere, with its topology of pointwise convergence, is a Polish group.

(h) Let G be a topological group carrying Haar measures. Show that it is extremely amenable iff its topology is the indiscrete topology. (*Hint*: 443L.)

493Y Further exercises (a) For a Boolean algebra $\mathfrak{A}$ and a group G with identity e, write $S(\mathfrak{A}; G)$ for the set of partitions of unity $\langle a_g\rangle_{g\in G}$ in $\mathfrak{A}$ such that $\{g : a_g \neq e\}$ is finite. For $\langle a_g\rangle_{g\in G}$, $\langle b_g\rangle_{g\in G} \in S(A)$, write $\langle a_g\rangle_{g\in G} \cdot \langle b_g\rangle_{g\in G} = \langle c_g\rangle_{g\in G}$ where $c_g = \sup\{a_h \cap b_{h^{-1}g} : h \in G\}$ for $g \in G$. (i) Show that under this operation $S(\mathfrak{A}; G)$ is a group. (ii) Show that if we write $h\chi a$ for the member $\langle a_g\rangle_{g\in G}$ of $S(\mathfrak{A}; G)$ such that $a_h = a$ and $a_g = 0$ for other $g \in G$, then $g\chi a \cdot h\chi b = (gh)\chi(a \cap b)$, and $S(\mathfrak{A}; G)$ is generated by $\{g\chi a : g \in G, a \in \mathfrak{A}\}$. (iii) Show that if $\mathfrak{A} = \Sigma/\mathcal{I}$ where Σ is an algebra of subsets of a set X and $\mathcal{I}$ is an ideal of Σ, then $S(\mathfrak{A}; G)$ can be identified with a space of equivalence classes in a suitable subgroup of G^X. (iv) Devise a universal mapping theorem for the construction $S(\mathfrak{A}; G)$ to match 361F in the case $(G, \cdot) = (\mathbb{R}, +)$. (v) Now suppose that $(\mathfrak{A}, \bar{\mu})$ is a measure algebra and that G is a topological group. Show that we have a topology on $S(\mathfrak{A}, G)$, making it a topological group, for which basic neighbourhoods of the identity $e\chi 1$ are of the form $V(c, \epsilon, U) = \{\langle a_g\rangle_{g\in G} : \bar{\mu}(c \cap \sup_{g\in G\setminus U} a_g) \leq \epsilon\}$ with $\bar{\mu}c < \infty$, $\epsilon > 0$ and U a neighbourhood of the identity in G. (vi) Show that if G is an amenable locally compact Hausdorff group and $(\mathfrak{A}, \bar{\mu})$ is an atomless measure algebra, then $S(\mathfrak{A}; G)$ is extremely amenable. (*Hint*: Pestov p01.) *(vi) Explore possible constructions of spaces $L^0(\mathfrak{A}; G)$. (See Hartman & Mycielski 58.)

(b) Let $(\mathfrak{A}, \bar{\mu})$ be an atomless totally finite measure algebra; give $\mathfrak{A}$ its measure metric. Show that the isometry group of $\mathfrak{A}$, with its topology of pointwise convergence, is extremely amenable. (*Hint*: every isometry of $\mathfrak{A}$ is of the form $a \mapsto c \triangle \pi a$, where $c \in \mathfrak{A}$ and $\pi \in \mathrm{Aut}_{\bar{\mu}}\mathfrak{A}$; now use 493Bc.)

(c) Let $(\mathfrak{A}, \bar{\mu})$ be an atomless probability algebra and $\pi : \mathfrak{A} \to \mathfrak{A}$ an ergodic measure-preserving automorphism. (i) Show that for any $n \geq 1$ there is a periodic measure-preserving automorphism ϕ of period n and support 1 such that the support of $\phi^{-1}\pi$ has measure at most $\frac{2}{n}$. (*Hint*: 386C.) (ii) Show that $\{\phi\pi\phi^{-1} : \phi \in \mathrm{Aut}_{\bar{\mu}}\mathfrak{A}\}$ is dense in $\mathrm{Aut}_{\bar{\mu}}\mathfrak{A}$ with its pointwise topology as described in 493H. (*Hint*: any two automorphisms with period n and support 1 are conjugate.)

(d) Let $(\mathfrak{A}, \bar{\mu})$ be the measure algebra of Lebesgue measure on $[0,1]$, and $\mathrm{Aut}_{\bar{\mu}}\mathfrak{A}$ the Polish group of measure-preserving automorphisms of $\mathfrak{A}$ (493Xe). (i) Show that the entropy function h of 385M is Borel measurable. (*Hint*: 385Xr.) (ii) Show that the set of ergodic measure-preserving automorphisms is a G_δ set in $\mathrm{Aut}_{\bar{\mu}}\mathfrak{A}$. (*Hint*: let $D \subseteq \mathfrak{A}$ be a countable dense set. Show that $\pi \in \mathrm{Aut}_{\bar{\mu}}\mathfrak{A}$ is ergodic iff $\lim_{n\to\infty} \|\frac{1}{n+1}\sum_{i=0}^{n} \chi(\pi^i d) - \bar{\mu}d \cdot \chi d\|_1 = 0$ for every $d \in D$.)

493 Notes and comments In writing this section I have relied heavily on PESTOV 99 and PESTOV P01, where you may find many further examples of extremely amenable groups. It is a striking fact that while the theories of locally compact groups and extremely amenable groups are necessarily almost entirely separate (493K), both are dependent on measure theory. Curiously, what seems to have been the first non-trivial extremely amenable group to be described was found in the course of investigating the Control Measure Problem (HERER & CHRISTENSEN 75).

The theory of locally compact groups has for seventy years now been a focal point for measure theory. Extremely amenable groups have not yet had such an influence. But they encourage us to look again at concentration-of-measure theorems, which are of the highest importance for quite separate reasons. In all four of the principal examples of this section we need concentration of measure in product spaces (493E-493F), permutation groups (493H) or on spheres in Euclidean space (493J). 493E and 493F are special cases of a general result in PESTOV P01 (493Ya(vi)) which itself extends an idea from GLASNER 98. I note that 493E needs only concentration of measure in $\{0,1\}^I$, while 493F demands something rather closer to the full strength of Talagrand's theorem 492D.

I have expressed 493J as a theorem about the isometry groups of spheres in infinite-dimensional inner product spaces; of course these are isomorphic to the orthogonal groups of the whole spaces with their strong operator topologies (476Xi). Adapting the basic concentration-of-measure theorem 476O to the required lemma 493I involves an instructive application of ideas from §443.

494 Cubes in product spaces

I offer a brief note on a special property of (Radon) product measures.

494A Proposition Let $(\mathfrak{A},\bar\mu)$ be a semi-finite measure algebra with its measure-algebra topology (323A). Suppose that $A\subseteq\mathfrak{A}$ is an uncountable analytic set. Then there is a compact set $L\subseteq A$, homeomorphic to $\{0,1\}^{\mathbb{N}}$, such that $\inf L\neq 0$ in $\mathfrak{A}$.

proof $A\setminus\{0\}$ is still an uncountable analytic subset of $\mathfrak{A}$. By 423J, it has a subset homeomorphic to $\{0,1\}^{\mathbb{N}}\cong\mathcal{P}\mathbb{N}$; let $f:\mathcal{P}\mathbb{N}\to A\setminus\{0\}$ be an injective continuous function. Because $(\mathfrak{A},\bar\mu)$ is semi-finite, there is an $a\subseteq f(\emptyset)$ such that $0<\bar\mu a<\infty$; set $\delta=\bar\mu a$. Note that $(I,J)\mapsto\bar\mu(a\cap f(I)\setminus f(J)):(\mathcal{P}\mathbb{N})^2\to\mathbb{R}$ is continuous. Choose a sequence $\langle k_n\rangle_{n\in\mathbb{N}}$ in $\mathbb{N}$ inductively, as follows. Given $\langle k_i\rangle_{i<n}$, set $K_n=\{k_i:i<n\}$. For each $J\subseteq K_n$ we have $\lim_{r\to\infty}\bar\mu(a\cap f(J)\setminus f(J\cup\{r\}))=0$, so there is a k_n, greater than k_i for every $i<n$, such that $\bar\mu(a\cap f(J)\setminus f(J\cup\{k_n\}))\leq 2^{-2n-2}\delta$ for every $J\subseteq K_n$; continue.

Now

$$\bar\mu(a\cap\inf_{J\subseteq K_n}f(J))\geq\delta(\tfrac12+2^{-n-1})$$

for every $n\in\mathbb{N}$. **P** Induce on n. If $n=0$, then $a\cap\inf_{J\subseteq K_n}f(J)=a\cap f(\emptyset)$ has measure $\delta=\delta(\frac12+2^{-1})$. For the inductive step to $n+1\geq 1$, observe that

$$\begin{aligned}\bar\mu(a\cap\inf_{J\subseteq K_{n+1}}f(J))&=\bar\mu(a\cap\inf_{J\subseteq K_n}f(J)\cap f(J\cup\{k_n\}))\\&\geq\bar\mu(a\cap\inf_{J\subseteq K_n}f(J))-\sum_{J\subseteq K_n}\bar\mu(a\cap f(J)\setminus f(J\cup\{k_n\}))\\&\geq\delta(\tfrac12+2^{-n-1})-\sum_{J\subseteq K_n}2^{-2n-2}\delta\end{aligned}$$

(by the inductive hypothesis and the choice of k_n)

$$=\delta(\tfrac12+2^{-n-2}).$$

So the induction proceeds. **Q**

Set $K=\{k_i:i\in\mathbb{N}\}$, $c=\inf\{f(J):J\subseteq K\text{ is finite}\}$. Then

$$\bar\nu(a\cap c)=\inf_{n\in\mathbb{N}}\bar\mu(a\cap\inf_{J\subseteq K_n}f(J))\geq\tfrac{1}{2}\delta,$$

and $c\neq 0$. But now observe that $L=f[\mathcal{P}K]$ is a subset of A homeomorphic to $\mathcal{P}K$ and therefore to $\{0,1\}^{\mathbb{N}}$. Also $\{b:b\supseteq c\}$ is closed (323D(d-i)), so $C=\{J:f(J)\supseteq c\}$ is closed in $\mathcal{P}K$; as it includes the dense set $[K]^{<\omega}$, $C=\mathcal{P}K$ and $\inf L\supseteq c$ is non-zero.

494B Proposition (see Brodskiĭ 49, Eggleston 54) Let $(X,\mathfrak{T},\Sigma,\mu)$ be an atomless Radon measure space, $(Y,\mathfrak{S},\mathrm{T},\nu)$ an effectively locally finite τ-additive topological measure space, and $\tilde\lambda$ the τ-additive product measure on $X\times Y$ (417G). Then if $W\subseteq X\times Y$ and $\tilde\lambda W>0$ there are a non-scattered compact set $K\subseteq X$ and a set $F\subseteq Y$ of positive measure such that $K\times F\subseteq W$.

proof (a) To begin with (down to the end of (c)), let us suppose that both μ and ν are totally finite. Let $(\mathfrak{B},\bar\nu)$ be the measure algebra of ν. Because $\tilde\lambda$ is inner regular with respect to the closed sets, we may suppose that W is closed. In this case, writing λ for the c.l.d. product measure on $X\times Y$, there is a $W'\supseteq W$ such that $\lambda W'$ is defined and equal to $\tilde\lambda W$ (417C(iv)). By 418Tb, there is a μ-conegligible set X_0 such that $W'[\{x\}]\in\mathrm{T}$ for every $x\in X_0$, $B=\{W'[\{x\}]^\bullet:x\in X_0\}$ is separable for the measure-algebra topology of $\mathfrak{B}$, and $x\mapsto W'[\{x\}]^\bullet:X_0\to\mathfrak{B}$ is measurable. Now Fubini's theorem, applied in the form of 252D to λ and in the form of 417Ha to $\tilde\lambda$, tells us that

$$\int\nu W'[\{x\}]\mu(dx)=\lambda W'=\tilde\lambda W=\int\nu W[\{x\}]\mu(dx).$$

So $X_1=\{x:x\in X_0,\ W'[\{x\}]^\bullet=W[\{x\}]^\bullet\}$ is μ-conegligible. Since the topology of $\mathfrak{B}$ is metrizable (323Ad), B is separable and metrizable, and $x\mapsto W[\{x\}]^\bullet:X_1\to B$ is almost continuous (418J, applied to the subspace measure on X_1). Let $K^*\subseteq X_1$ be a compact set of non-zero measure such that $x\mapsto W[\{x\}]^\bullet:K^*\to\mathfrak{B}$ is continuous.

(b) There is a non-zero $c\in\mathfrak{B}$ such that $K_c=\{x:x\in K^*,\ c\subseteq W[\{x\}]^\bullet\}$ is compact and not scattered. **P** Because $x\mapsto W[\{x\}]^\bullet$ is continuous on K^*, $B^*=\{W[\{x\}]^\bullet:x\in K^*\}$ is compact and every K_c is compact. (i) If B^* is countable, then $K^*=\bigcup_{b\in B^*}K_b$, so there is some $c\in B^*$ such that $\mu K_c>0$. Let E be a non-negligible self-supporting subset of K_c; then (because μ is atomless, therefore zero on singletons) E has no isolated points. So K_c is not scattered. (ii) If B^* is uncountable, then by 494A there is a set $D\subseteq B^*$, homeomorphic to $\{0,1\}^{\mathbb{N}}$, with a non-zero lower bound c in $\mathfrak{B}$. Now $\{W[\{x\}]^\bullet:x\in K_c\}$ includes D, so $\{0,1\}^{\mathbb{N}}$ and therefore $[0,1]$ are continuous images of closed subsets of K_c and K_c is not scattered (4A2G(i-iv)). **Q**

(c) Set $K=K_c$. Then 414Ac tells us that

$$(\textstyle\bigcap_{x\in K}W[\{x\}])^\bullet=\inf_{x\in K}W[\{x\}]^\bullet\supseteq c$$

is non-zero, so $F=\bigcap_{x\in K}W[\{x\}]$ is non-negligible; while $K\times F\subseteq W$. So we have found appropriate sets K and F, at least when μ and ν are totally finite.

(d) For the general case, we need observe only that by 417C(iii) there are $X'\in\Sigma$ and $Y'\in\mathrm{T}$, both of finite measure, such that $\tilde\lambda(W\cap(X'\times Y'))>0$. Now the subspace measure $\mu_{X'}$ on X' is atomless and Radon (214Ja, 416Rb), the subspace measure $\nu_{Y'}$ on Y' is τ-additive (414K), and the τ-additive product of $\mu_{X'}$ and $\nu_{Y'}$ is the subspace measure on $X'\times Y'$ induced by $\tilde\lambda$ (417I). So we can apply (a)-(c) to $\mu_{X'}$ and $\nu_{Y'}$ to see that there are a non-scattered compact set $K\subseteq X'$ and a non-negligible measurable set $F\subseteq Y'$ such that $K\times F\subseteq W$.

494C Proposition (see Ciesielski & Pawlikowski 03) Let $\langle(X_i,\mathfrak{T}_i,\Sigma_i,\mu_i)\rangle_{i\in I}$ be a countable family of atomless Radon probability spaces, and $\tilde\lambda$ the product Radon probability measure on $X=\prod_{i\in I}X_i$. If $W\subseteq X$ and $\tilde\lambda W>0$, there is a family $\langle K_i\rangle_{i\in I}$ such that $K_i\subseteq X_i$ is a non-scattered compact set for each $i\in I$ and $\prod_{i\in I}K_i\subseteq W$.

proof (a) To begin with, let us suppose that $I=\mathbb{N}$. For each $n\in\mathbb{N}$, set $Y_n=\prod_{i\geq n}X_i$ and let $\tilde\lambda_n$ be the product Radon probability measure on Y_n, so that $\tilde\lambda_0=\tilde\lambda$ and $\tilde\lambda_n$ can be identified with the product of μ_n and $\tilde\lambda_{n+1}$ (417J). Using 494B repeatedly, we can find non-scattered compact sets $K_n\subseteq X_n$ and closed non-negligible sets $W_n\subseteq Y_n$ such that $W_0\subseteq W$ and $K_n\times W_{n+1}\subseteq W_n$ for every n. In this case,

$\prod_{i<n} K_i \times W_n \subseteq W_0$ for every n. If $x \in \prod_{i\in\mathbb{N}} K_i$, then there is for each $n \in \mathbb{N}$ an $x_n \in \prod_{i<n} K_i \times W_n$ such that $x_n{\restriction}n = x{\restriction}n$, just because W_n is not empty. But now every $x_n \in W_0$ and

$$x = \lim_{n\to\infty} x_n \in W_0 \subseteq W.$$

As x is arbitrary, $\prod_{i\in\mathbb{N}} K_i \subseteq W$.

(b) For the general case, we may suppose that $I \subseteq \mathbb{N}$. For $i \in \mathbb{N} \setminus I$, take $(X_i, \mathfrak{T}_i, \Sigma_i, \mu_i)$ to be $[0,1]$ with Lebesgue measure. Set $\tilde{W} = \{x : x \in \prod_{i\in\mathbb{N}} X_i,\ x{\restriction}I \in W\}$. By (a), there are non-scattered compact sets $K_i \subseteq X_i$ such that $\prod_{i\in\mathbb{N}} K_i \subseteq \tilde{W}$, in which case $\prod_{i\in I} K_i \subseteq W$, as required.

494X Basic exercises (a) Let $(X, \mathfrak{T}, \Sigma, \mu)$ be a Radon measure space, $(Y, \mathfrak{S}, \mathrm{T}, \nu)$ an effectively locally finite τ-additive topological measure space, and $\tilde{\lambda}$ the τ-additive product measure on $X \times Y$. Show that if $W \subseteq X \times Y$ and $\tilde{\lambda}W > 0$ there are a compact set $K \subseteq X$ and a set $F \subseteq Y$ of positive measure such that $K \times F \subseteq W$ and K is either non-scattered or non-negligible.

(b) Let $(X, \mathfrak{T}, \Sigma, \mu)$ be an atomless Radon measure space, (Y, T, ν) any measure space, and λ the c.l.d. product measure on $X \times Y$. Show that if $W \subseteq X \times Y$ and $\lambda W > 0$ there are a non-scattered compact set $K \subseteq X$ and a set $F \subseteq Y$ of positive measure such that $K \times F \subseteq W$. (*Hint*: reduce to the case in which ν is totally finite and T is countably generated, so that the completion of ν is a quasi-Radon measure for an appropriate second-countable topology.)

(c) Let $\langle (X_i, \mathfrak{T}_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be any family of atomless Radon probability spaces, and λ the ordinary product measure on $X = \prod_{i\in I} X_i$. Show that if $W \subseteq X$ and $\lambda W > 0$ then there are non-scattered compact sets $K_i \subseteq X_i$ for $i \in I$ such that $\prod_{i\in I} K_i \subseteq W$.

(d) Let $\langle (X_i, \mathfrak{T}_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a countable family of atomless Radon probability spaces, and $W \subseteq \prod_{i\in I} X_i$ a set with positive measure for the Radon product of $\langle \mu_i\rangle_{i\in I}$. Show that there are atomless Radon probability measures ν_i on X_i such that W is conegligible for the Radon product of $\langle \nu_i\rangle_{i\in I}$. (*Hint*: 439Xh(vii).)

494Y Further exercises (a) Let $\langle (X_i, \mathfrak{T}_i, \Sigma_i, \mu_i)\rangle_{i\in I}$ be a family of atomless perfect probability spaces, and λ the ordinary product measure on $X = \prod_{i\in I} X_i$. Show that if $W \subseteq X$ and $\lambda W > 0$ then there are sets $K_i \subseteq X_i$ for $i \in I$, all of cardinal $\mathfrak{c}$, such that $\prod_{i\in I} K_i \subseteq W$.

494 Notes and comments I have already noted (325Yc) that a set W of positive measure in a product space need not include the product of two sets of positive measure; this fact is also the basis of 419E. Here, however, we see that if one of the factors is a Radon measure space then W does include the product of a non-trivial compact set and a set of positive measure. There are many possible variations on the result, corresponding to different product measures (494B, 494Xb) and different notions of 'non-trivial' (494Xa, 494Ya). The most important of the latter seems to be the idea of a 'non-scattered' compact set K; this is a quick way of saying that $[0,1]$ is a continuous image of K, which is a little stronger than saying that $\#(K) \geq \mathfrak{c}$, and arises naturally from the proof of 494B.

495 Poisson point processes

A classical challenge in probability theory is to formulate a consistent notion of 'random set'. Simple geometric considerations lead us to a variety of measures which are both interesting and important. All these are manifestly special constructions. Even in the most concrete structures, we have to make choices which come to seem arbitrary as soon as we are conscious of the many alternatives. There is however one construction which has a claim to pre-eminence because it is both robust under the transformations of abstract measure theory and has striking properties when applied to familiar measures (to the point, indeed, that it is relevant to questions in physics and chemistry). This gives the 'Poisson point processes' of 495D-495E. In this section I give a brief introduction to the measure-theoretic aspects of this construction.

495A Poisson distributions We need a little of the elementary theory of Poisson distributions.

(a) The **Poisson distribution** with parameter $\gamma > 0$ is the point-supported Radon probability measure ν_γ on $\mathbb{R}$ such that $\nu_\gamma\{n\} = \frac{\gamma^n}{n!}e^{-\gamma}$ for every $n \in \mathbb{N}$. (See 285Q and 285Xo.) Its expectation is $\sum_{n=1}^\infty \frac{\gamma^n}{(n-1)!}e^{-\gamma} = \gamma$. Since $\nu_\gamma\mathbb{N} = 1$, ν_γ can be identified with the corresponding subspace measure on $\mathbb{N}$. It will be convenient to allow $\gamma = 0$, so that the probability measure on $\mathbb{R}$ or $\mathbb{N}$ with support $\{0\}$ is a 'Poisson distribution with expectation 0'.

(b) The convolution of two Poisson distributions is a Poisson distribution. **P** If α, $\beta > 0$ then

$$(\nu_\alpha * \nu_\beta)(\{n\}) = \int \nu_\beta(\{n\} - t)\nu_\alpha(dt)$$

(444A)

$$= \sum_{i=0}^n \frac{\beta^{n-i}}{(n-i)!}e^{-\beta} \cdot \frac{\alpha^i}{i!}e^{-\alpha}$$

$$= e^{-\alpha-\beta}\frac{1}{n!}\sum_{i=0}^n \frac{n!}{i!(n-i)!}\alpha^i\beta^{n-i} = \frac{(\alpha+\beta)^n}{n!}e^{-\alpha-\beta}$$

for every $n \in \mathbb{N}$, so $\nu_\alpha * \nu_\beta = \nu_{\alpha+\beta}$. **Q** So if f and g are independent random variables with Poisson distributions then $f + g$ has a Poisson distribution (272S).

(c) If $\langle f_i\rangle_{i\in I}$ is a countable independent family of random variables with Poisson distributions, and $\alpha = \sum_{i\in I}\mathbb{E}(f_i)$ is finite, then $f = \sum_{i\in I} f_i$ is defined a.e. and has a Poisson distribution with expectation α. **P** For finite I we can induce on $\#(I)$, using (b) (and 272L) for the inductive step. For the infinite case we can suppose that $I = \mathbb{N}$. In this case $f_i \geq 0$ a.e. for each i so $f = \sum_{i=0}^\infty f_i$ is defined a.e. and has expectation α, by B.Levi's theorem. Setting $g_n = \sum_{i=0}^n f_i$ for each n, so that g_n has a Poisson distribution with expectation $\beta_n = \sum_{i=0}^n \alpha_i$, we have

$$\Pr(f \leq \gamma) = \lim_{n\to\infty}\Pr(g_n \leq \gamma) = \lim_{n\to\infty}\sum_{i=0}^{\lfloor\gamma\rfloor}\frac{\beta_n^i}{i!}e^{-\beta_n} = \sum_{i=0}^{\lfloor\gamma\rfloor}\frac{\alpha^i}{i!}e^{-\alpha}$$

for every $\gamma \geq 0$, so f has a Poisson distribution with expectation α. **Q**

495B Theorem Let (X, Σ, μ) be a measure space. Set $\Sigma^f = \{E : E \in \Sigma, \mu E < \infty\}$. Then for any $\gamma > 0$ there are a probability space $(\Omega, \Lambda, \lambda)$ and a family $\langle g_E\rangle_{E\in\Sigma^f}$ of random variables on Ω such that

(i) for every $E \in \Sigma^f$, g_E has a Poisson distribution with expectation $\gamma\mu E$;

(ii) whenever $\langle E_i\rangle_{i\in I}$ is a disjoint family in Σ^f, then $\langle g_{E_i}\rangle_{i\in I}$ is stochastically independent;

(iii) whenever $\langle E_i\rangle_{i\in\mathbb{N}}$ is a disjoint sequence in Σ^f with union $E \in \Sigma^f$, then $g_E =_{\text{a.e.}} \sum_{i=0}^\infty g_{E_i}$.

proof (a) Let $\mathcal{H} \subseteq \{H : H \in \Sigma, 0 < \mu H < \infty\}$ be a maximal family such that $H \cap H'$ is negligible for all distinct H, $H' \in \mathcal{H}$. For $H \in \mathcal{H}$, let μ'_H be the normalized subspace measure defined by setting $\mu'_H E = \mu E/\mu H$ for $E \in \Sigma \cap \mathcal{P}H$, and λ_H the corresponding product probability measure on $H^{\mathbb{N}}$. Next, for $H \in \mathcal{H}$, let ν_H be the Poisson distribution with expectation $\gamma\mu H$, regarded as a probability measure on $\mathbb{N}$. Let λ be the product measure on $\Omega = \prod_{H\in\mathcal{H}}(\mathbb{N} \times H^{\mathbb{N}})$, giving each $\mathbb{N} \times H^{\mathbb{N}}$ the product measure $\nu_H \times \lambda_H$. For $\omega \in \Omega$, write $m_H(\omega)$, $x_{Hj}(\omega)$ for its coordinates, so that $\omega = \langle(m_H(\omega), \langle x_{Hj}(\omega)\rangle_{j\in\mathbb{N}})\rangle_{H\in\mathcal{H}}$.

(b) For $H \in \mathcal{H}$ and $E \in \Sigma$, set $g_{HE}(\omega) = \#(\{j : j < m_H(\omega), x_{Hj}(\omega) \in E\})$. Then g_{HE} is measurable and has a Poisson distribution with expectation $\gamma\mu(H \cap E)$; moreover, if $E_0, \ldots, E_r \in \Sigma$ are disjoint, then $g_{HE_0}, \ldots, g_{HE_r}$ are independent. **P** It is enough to examine the case in which the E_i cover X. Then for any $n_0, \ldots, n_r \in \mathbb{N}$ with sum n,

$$\begin{aligned}
&\lambda\{\omega : g_{HE_i}(\omega) = n_i \text{ for every } i \le r\}\\
&\quad = \lambda\{\omega : \#(\{j : j < m_H(\omega),\, x_{Hj} \in E_i\}) = n_i \text{ for every } i \le r\}\\
&\quad = \lambda\{\omega : m_H(\omega) = n,\, \#(\{j : j < n,\, x_{Hj} \in E_i\}) = n_i \text{ for every } i \le r\}\\
&\quad = \sum_{\substack{J_0,\dots,J_r \text{ partition } n\\ \#(J_i)=n_i \text{ for each } i\le r}} \lambda\{\omega : m_H(\omega) = n,\, x_{Hj} \in E_i \text{ whenever } i \le r,\, j \in I_i\}\\
&\quad = \sum_{\substack{J_0,\dots,J_r \text{ partition } n\\ \#(J_i)=n_i \text{ for each } i\le r}} \frac{(\gamma\mu H)^n}{n!} e^{-\gamma\mu H} \prod_{i=0}^{r} \big(\frac{\mu(H\cap E_i)}{\mu H}\big)^{n_i}\\
&\quad = \frac{n!}{n_0!\dots n_r!}\frac{1}{n!} e^{-\gamma\mu H} \prod_{i=0}^{r} (\gamma\mu(H\cap E_i))^{n_i}\\
&\quad = \prod_{i=0}^{r} \frac{(\gamma\mu(H\cap E_i))^{n_i}}{n_i!} e^{-\gamma\mu(H\cap E_i)},
\end{aligned}$$

which is just what we wanted to know. **Q**

Obviously $g_{HE} = \sum_{i=0}^{\infty} g_{HE_i}$ whenever $\langle E_i\rangle_{i\in\mathbb{N}}$ is a sequence in Σ with union E.

(c) Suppose that $H_0, \dots, H_n \in \mathcal{H}$ are distinct and $E_0, \dots, E_r \in \Sigma$ are disjoint. Then the random variables $g_{H_jE_i}$ are independent. **P** For each $j \le n$, $g_{H_jE_i}$ is Λ_{H_j}-measurable, where Λ_{H_j} is the σ-algebra of subsets of Ω which are measured by λ and determined by the single coordinate H_j in the product $\prod_{H\in\mathcal{H}}(\mathbb{N}\times H^{\mathbb{N}})$. Now the σ-algebras Λ_{H_j} are independent (272Ma). So if we have any family $\langle n_{ij}\rangle_{i\le r, j\le n}$ in $\mathbb{N}$,

$$\begin{aligned}
&\lambda\{\omega : g_{H_jE_i}(\omega) = n_{ij} \text{ for every } i \le r, j \le n\}\\
&\qquad = \prod_{j=0}^{n} \lambda\{\omega : g_{H_jE_i}(\omega) = n_{ij} \text{ for every } i \le r\}\\
&\qquad = \prod_{j=0}^{n}\prod_{i=0}^{r} \lambda\{\omega : g_{H_jE_i}(\omega) = n_{ij}\}
\end{aligned}$$

by (b); and this is what we need to know. **Q**

(d) For $E \in \Sigma^f$, set $\mathcal{H}_E = \{H : H \in \mathcal{H},\, \mu(E\cap H) > 0\}$; then $\mathcal{H}_E$ is countable, because $\mathcal{H}$ is almost disjoint, and $\mu E = \sum_{H\in\mathcal{H}_E} \mu(H\cap E)$, because $\mathcal{H}$ is maximal. Set $g_E(\omega) = \sum_{H\in\mathcal{H}_E} g_{HE}(\omega)$ when this is finite. Then g_E is defined a.e. and has a Poisson distribution with expectation $\gamma\mu E$ (495Ac). Also $\langle g_{E_i}\rangle_{i\in I}$ are independent whenever $\langle E_i\rangle_{i\in I}$ is a disjoint family in Σ. **P** It is enough to deal with the case of finite I (272Bb). Set $\mathcal{H}^* = \bigcup_{i\in I}\mathcal{H}_{E_i}$, so that $\mathcal{H}^*$ is countable, and for $i \in I$ set $g_i' = \sum_{H\in\mathcal{H}^*} g_{HE_i}$. Then each g_i' is equal almost everywhere to the corresponding g_{E_i}, and $\langle g_i'\rangle_{i\in I}$ is independent, by 272K. (The point is that each g_i' is Λ_i^*-measurable, where Λ_i^* is the σ-algebra generated by $\{g_{HE_i} : H \in \mathcal{H}\}$, and 272K assures us that the Λ_i^* are independent.) It follows at once that $\langle g_{E_i}\rangle_{i\in I}$ is independent (272H). **Q** This proves (i) and (ii).

(e) Similarly, if $\langle E_i\rangle_{i\in\mathbb{N}}$ is a disjoint sequence in Σ^f with union $E \in \Sigma^f$, set $\mathcal{H}^* = \mathcal{H}_E \cup \bigcup_{i\in\mathbb{N}}\mathcal{H}_{E_i}$. For each $i \in \mathbb{N}$, set $g_i' = \sum_{H\in\mathcal{H}^*} g_{HE_i}$; then $g_i' =_{\text{a.e.}} g_{E_i}$. Now

$$\sum_{i=0}^{\infty} g_{E_i} =_{\text{a.e.}} \sum_{i=0}^{\infty} g_i' = \sum_{H\in\mathcal{H}^*}\sum_{i=0}^{\infty} g_{HE_i} = \sum_{H\in\mathcal{H}^*} g_{HE} =_{\text{a.e.}} g_E,$$

as required by (iii).

495C Lemma Let X be a set and $\mathcal{E}$ a subring of the Boolean algebra $\mathcal{P}X$. Let $\mathcal{H}$ be the family of sets of the form

$$\{S : S \subseteq X, \#(S \cap E_i) = n_i \text{ for every } i \in I\}$$

where $\langle E_i\rangle_{i\in I}$ is a finite disjoint family in $\mathcal{E}$ and $n_i \in I$ for every $i \in I$. Then the Dynkin class $\mathrm{T} \subseteq \mathcal{P}(\mathcal{P}X)$ generated by $\mathcal{H}$ is the σ-algebra of subsets of $\mathcal{P}X$ generated by $\mathcal{H}$.

proof Let Q be the set of functions q from finite subsets of $\mathcal{E}$ to $\mathbb{N}$, and for $q \in Q$ set

$$H_q = \{S : S \subseteq X, \#(S \cap E) = q(E) \text{ for every } E \in \operatorname{dom} q\}.$$

Our family $\mathcal{H}$ is just $\{H_q : q \in Q, \operatorname{dom} q \text{ is disjoint}\}$.

If $q \in Q$ and $\operatorname{dom} q$ is a subring of $\mathcal{E}$, then $H_q \in \mathrm{T}$. **P** Being a finite Boolean ring, $\operatorname{dom} q$ is a Boolean algebra; let $\mathcal{A}$ be the set of its atoms. Then H_q is either empty or equal to $H_{q\restriction\mathcal{A}}$; in either case it belongs to T. **Q**

If q is any member of Q, then $H_q \in \mathrm{T}$. **P** Let $\mathcal{E}$ be the subring of $\mathcal{P}X$ generated by $\operatorname{dom} q$. Then $H_q = \bigcup_{q\subseteq q'\in Q, \operatorname{dom} q' = \mathcal{E}} H_{q'}$ is the union of a finite disjoint family in T, so belongs to T. **Q**

Now observe that $\mathcal{H}_1 = \{H_q : q \in Q\} \cup \{\emptyset\}$ is a subset of T closed under finite intersections, so by the Monotone Class Theorem (136B) T includes the σ-algebra generated by $\mathcal{H}_1$, and must be precisely the σ-algebra generated by $\mathcal{H}$.

495D Theorem Let (X, Σ, μ) be an atomless measure space. Set $\Sigma^f = \{E : E \in \Sigma, \mu E < \infty\}$; for $E \in \Sigma^f$, set $f_E(S) = \#(S \cap E)$ when $S \subseteq X$ meets E in a finite set. Let T be the σ-algebra of subsets of $\mathcal{P}X$ generated by sets of the form $\{S : f_E(S) = n\}$ where $E \in \Sigma^f$ and $n \in \mathbb{N}$. Then for any $\gamma > 0$ there is a unique probability measure ν with domain T such that

(i) for every $E \in \Sigma^f$, f_E is measurable and has a Poisson distribution with expectation $\gamma\mu E$;

(ii) whenever $\langle E_i\rangle_{i\in I}$ is a disjoint family in Σ^f, then $\langle f_{E_i}\rangle_{i\in I}$ is stochastically independent.

proof (a) Let $\mathcal{H}$, $\langle\nu_H\rangle_{H\in\mathcal{H}}$, $\langle\mu_H\rangle_{H\in\mathcal{H}}$, $\langle\mu'_H\rangle_{H\in\mathcal{H}}$, $\langle\lambda_H\rangle_{H\in\mathcal{H}}$, Ω, λ, $\langle\mathcal{H}_E\rangle_{E\in\Sigma^f}$ and $\langle g_E\rangle_{E\in\Sigma^f}$ be as in the proof of 495B. Note that all the μ'_H are atomless (234Ff). Define $\phi : \Omega \to \mathcal{P}X$ by setting

$$\phi(\omega) = \{x_{Hj}(\omega) : H \in \mathcal{H}, j < m_H(\omega)\}$$

for $\omega \in \Omega$.

(b) For $E \in \Sigma^f$, let A_E be the set of those $\omega \in \Omega$ such that

either there are $H \in \mathcal{H} \setminus \mathcal{H}_E$, $j \in \mathbb{N}$ such that $x_{Hj}(\omega) \in E$

or there are distinct H, $H' \in \mathcal{H}_E$ and $j \in \mathbb{N}$ such that $x_{Hj}(\omega) \in H'$

or there is an $H \in \mathcal{H}$ such that the $x_{Hj}(\omega)$, for $j \in \mathbb{N}$, are not all distinct.

Then for any sequence $\langle E_i\rangle_{i\in\mathbb{N}}$ in Σ^f, $\lambda_*(\bigcup_{i\in\mathbb{N}} A_{E_i}) = 0$. **P** Set $\mathcal{H}^* = \bigcup_{i\in\mathbb{N}} \mathcal{H}_{E_i}$, so that $\mathcal{H}^*$ is a countable subset of $\mathcal{H}$. For $H \in \mathcal{H}$, set

$$F_H = H \setminus (\bigcup\{E_i : i \in \mathbb{N}, H \cap E_i \text{ is negligible}\} \cup \bigcup\{H' : H' \in \mathcal{H}^*, H' \neq H\}),$$

$$W_H = \{\boldsymbol{x} : \boldsymbol{x} \in H^{\mathbb{N}} \text{ is injective}\},$$

so that F_H is μ'_H-conegligible and W_H is λ_H-conegligible (because μ'_H is atomless, see 254V). Now

$$\Omega \setminus \bigcup_{k\in\mathbb{N}} A_{E_k} \supseteq \prod_{H\in\mathcal{H}} (\mathbb{N} \times (W_H \cap F_H^{\mathbb{N}}))$$

has full outer measure in Ω, by 254Lb, and its complement has zero inner measure (413Ec). **Q**

It follows that there is a probability measure $\tilde\lambda$ on Ω, extending λ, such that $\tilde\lambda A_E = 0$ for every $E \in \Sigma^f$ (417A). Let ν_0 be the image measure $\tilde\lambda\phi^{-1}$.

(c) If $E \in \Sigma^f$ and $\omega \in \Omega \setminus A_E$, then $f_E(\phi(\omega)) = g_E(\omega)$ if either is defined. **P** If $H \in \mathcal{H}$, then all the $x_{Hj}(\omega)$ are distinct; if $H \in \mathcal{H} \setminus \mathcal{H}_E$, no $x_{Hj}(\omega)$ can belong to E; if H, $H' \in \mathcal{H}_E$ are distinct, then no $x_{Hj}(\omega)$ can belong to H'. So all the $x_{Hj}(\omega)$, $x_{H'k}(\omega)$ for H, $H' \in \mathcal{H}_E$ and j, $k \in \mathbb{N}$ must be distinct, and

$$\begin{aligned} f_E(\phi(\omega)) &= \#(\{x_{Hj}(\omega) : H \in \mathcal{H},\, j < m_H(\omega),\, x_{Hj}(\omega) \in E\}) \\ &= \#(\{(H,j) : H \in \mathcal{H}_E,\, j < m_H(\omega),\, x_{Hj}(\omega) \in E\}) \\ &= \sum_{H \in \mathcal{H}_E} g_{HE}(\omega) = g_E(\omega) \end{aligned}$$

if any of these is finite. **Q** It follows at once that if $E_0, \dots, E_r \in \Sigma^f$ are disjoint, then $\{\omega : f_{E_i}(\phi(\omega)) = g_{E_i}(\omega)$ for every $i \le r\}$ is $\tilde{\lambda}$-conegligible, so that if $n_0, \dots, n_r \in \mathbb{N}$ then

$$\begin{aligned} \nu_0\{S : f_{E_i}(S) = n_i \text{ for every } i \le r\} &= \tilde{\lambda}\{\omega : f_{E_i}(\phi(\omega)) = n_i \text{ for every } i \le r\} \\ &= \tilde{\lambda}\{\omega : g_{E_i}(\omega) = n_i \text{ for every } i \le r\} \\ &= \prod_{i=0}^{r} \frac{(\gamma\mu E_i)^{n_i}}{n_i!} e^{-\gamma\mu E_i}. \end{aligned}$$

Thus every f_{E_i} is finite ν_0-a.e., belongs to $\mathcal{L}^0(\nu_0)$ and has a Poisson distribution with the appropriate expectation, and they are independent.

(d) As T is defined to be the σ-algebra generated by the family $\{f_E : E \in \Sigma^f\}$, it is included in the domain of ν_0. Set $\nu = \nu_0 \restriction \mathrm{T}$; then ν has the properties (i) and (ii). To see that it is unique, observe that if ν' also has these properties, then $\{A : \nu A = \nu' A\}$ is a Dynkin class containing every set of the form

$$\{S : f_{E_i}(S) = n_i \text{ for } i \le r\}$$

where $E_0, \dots, E_r \in \Sigma^f$ are disjoint and $n_0, \dots, n_r \in \mathbb{N}$. By 495C it contains the σ-algebra generated by this family, which is T. So ν and ν' agree on T, and are equal.

495E Definition In the context of 495D, I will call the completion of ν the **Poisson point process** on X with density γ.

Note that the Poisson point process on (X, μ) with density $\gamma > 0$ is identical with the Poisson point process on $(X, \gamma\mu)$ with density 1. There would therefore be no real loss of generality in the main theorems of this section if I spoke only of point processes with density 1. I retain the extra parameter because applications frequently demand it, and the formulae will be more useful with the γs in their proper places; moreover, there are important ideas associated with variations in γ, as in 495Xd.

495F Proposition Let (X, Σ, μ) be a perfect atomless measure space, and $\gamma > 0$. Then the Poisson point process on X with density γ is a perfect probability measure.

proof I refer to the construction in 495B-495D. In (b) of the proof of 495D, use the construction set out in the proof of 417A, so that the domain $\tilde{\Lambda}$ of $\tilde{\lambda}$ is precisely the family of sets of the form $W \triangle A$ where W belongs to the domain Λ of the product measure λ and A belongs to the σ-ideal $\mathcal{A}^*$ generated by $\{A_E : E \in \Sigma^f\}$. Then $\tilde{\lambda}$ is perfect. **P** Let $h : \Omega \to \mathbb{R}$ be a $\tilde{\Lambda}$-measurable function and $W \in \tilde{\Lambda}$ a set of non-zero measure. Then there are a $W' \in \Lambda$ and an $A \in \mathcal{A}^*$ such that $W \triangle W' \subseteq A$ and $h \restriction \Omega \setminus A$ is Λ-measurable; let $\langle E_n \rangle_{n \in \mathbb{N}}$ be a sequence in Σ^f such that $A \subseteq \bigcup_{n \in \mathbb{N}} A_{E_n}$, and $h_1 : \Omega \to \mathbb{R}$ a Λ-measurable function agreeing with h on $\Omega \setminus A$. Set $\mathcal{H}^* = \bigcup_{n \in \mathbb{N}} \mathcal{H}_{E_n}$, so that $\mathcal{H}^*$ is countable. As in the proof of 495D, set

$$F_H = H \setminus (\bigcup\{E_n : n \in \mathbb{N},\, H \cap E_n \text{ is negligible}\} \cup \bigcup\{H' : H' \in \mathcal{H}^*,\, H' \ne H\}),$$

$$W_H = \{\boldsymbol{x} : \boldsymbol{x} \in H^{\mathbb{N}} \text{ is injective}\},$$

for $H \in \mathcal{H}$, so that $W'_H = W_H \cap F_H^{\mathbb{N}}$ is λ_H-conegligible. Set $\Omega' = \prod_{H \in \mathcal{H}} (\mathbb{N} \times W'_H)$. This is disjoint from every A_{E_n} (as in 495D) and therefore from A. The subspace measure $\lambda_{\Omega'}$ on Ω' induced by λ is just the product of the measures on $\mathbb{N} \times W'_H$ (254La). All of these are perfect (451Jc, 451Dc), so $\lambda_{\Omega'}$ is also perfect (451Jc again). Now

$$\lambda_{\Omega'}(W \cap \Omega') = \lambda_{\Omega'}(W' \cap \Omega') = \lambda W' = \tilde{\lambda} W > 0.$$

It follows that there is a compact set $K \subseteq h_1[W \cap \Omega']$ such that $\lambda_{\Omega'}(h_1^{-1}[K] \cap \Omega') > 0$. As h and h_1 agree on Ω', $K \subseteq h[W]$, while

$$\tilde{\lambda}h^{-1}[K] = \tilde{\lambda}h_1^{-1}[K]$$

(because $\tilde{\lambda}A = 0$)

$$= \lambda h_1^{-1}[K] = \lambda_{\Omega'}(h^{-1}[K] \cap \Omega') > 0.$$

As W and h are arbitrary, $\tilde{\lambda}$ is perfect. **Q**

It follows at once that the image measure $\tilde{\lambda}\phi^{-1}$ and its restriction to T are perfect (451Ea); finally, the completion is perfect, by 451Gc.

495G Proposition Let (X_1, Σ_1, μ_1) and (X_2, Σ_2, μ_2) be atomless measure spaces, and $f : X_1 \to X_2$ an inverse-measure-preserving function. Let $\gamma > 0$, and let ν_1, ν_2 be the Poisson point processes on X_1, X_2 respectively with density γ. Then $S \mapsto f[S] : \mathcal{P}X_1 \to \mathcal{P}X_2$ is inverse-measure-preserving for ν_1 and ν_2; in particular, $\mathcal{P}A$ has full outer measure for ν_2 whenever $A \subseteq X_2$ has full outer measure for μ_2.

proof Set $\psi(S) = f[S]$ for $S \subseteq X_1$.

(a) If $F \in \Sigma_2^f$, then $\{S : S \subseteq X_1,\ f\restriction f^{-1}[F] \cap S \text{ is not injective}\}$ is ν_1-negligible. **P** Let $n \in \mathbb{N}$. Set $\alpha = \frac{1}{n+1}\mu_2 F$. Because μ_2 is atomless, we can find a partition of F into sets $F_0, \dots, F_n$ of measure α. Now

$$\{S : f\restriction f^{-1}[F] \cap S \text{ is not injective}\} \subseteq \bigcup_{i \le n} \{S : \#(S \cap f^{-1}[F_i]) > 1\}$$

has ν_1-outer measure at most

$$(n+1)(1 - e^{-\gamma\alpha}(1 + \gamma\alpha)) \le (n+1)\alpha^2\gamma^2 = \frac{1}{n+1}(\gamma\mu_2 F)^2.$$

As n is arbitrary, $\{S : f\restriction f^{-1}[F] \cap S \text{ is not injective}\}$ is negligible. **Q**

(b) It follows that, for any $F \in \Sigma_2^f$ and $n \in \mathbb{N}$,

$$\{S : \#(f[S] \cap F) = n\} \triangle \{S : \#(S \cap f^{-1}[F]) = n\}$$

is ν_1-negligible and $\{S : \#(f[S] \cap F) = n\}$ is measured by ν_1. So if T_2 is the σ-algebra of subsets of $\mathcal{P}X_2$ generated by sets of the form $\{T : \#(F \cap T) = n\}$ for $F \in \Sigma_2^f$ and $n \in \mathbb{N}$, then ν_1 measures $\psi^{-1}[H]$ for every $H \in \mathrm{T}_2$. Next, if $\langle F_i \rangle_{i \in I}$ is a finite disjoint family in Σ_2^f and $n_i \in \mathbb{N}$ for $i \in I$,

$$\begin{aligned}\nu_1\{S : \#(f[S] \cap F_i) = n_i \text{ for every } i \in I\} &= \nu_1\{S : \#(S \cap f^{-1}[F_i]) = n_i \text{ for every } i \in I\} \\ &= \prod_{i \in I} \frac{(\gamma\mu_1 f^{-1}[F_i])^n}{n!} e^{-\gamma\mu_1 f^{-1}[F_i]}\end{aligned}$$

(because $\langle f^{-1}[F_i] \rangle_{i \in I}$ is a disjoint family in Σ_1^f)

$$= \prod_{i \in I} \frac{(\gamma\mu_2 F_i)^n}{n!} e^{-\gamma\mu_2 F_i}.$$

So the image measure $\nu_1\psi^{-1}$ satisfies (i) and (ii) of 495D, and must agree with ν_2 on T_2; that is, ψ is inverse-measure-preserving for ν_1 and $\nu_2\restriction \mathrm{T}_2$. As ν_1 is complete, ψ is inverse-measure-preserving for ν_1 and ν_2 (235Hc).

(c) If $A \subseteq X_2$ has full outer measure, then we can take μ_1 to be the subspace measure on $X_1 = A$ and $f(x) = x$ for $x \in A$. In this case, $\mathcal{P}A = \psi[\mathcal{P}A]$ must have full outer measure for ν_2.

495H Lemma Let $(\tilde{X}, \tilde{\Sigma}, \tilde{\mu})$ be an atomless σ-finite measure space, and $\gamma > 0$. Write μ_L for Lebesgue measure on $[0,1]$, μ' for the product measure on $X' = \tilde{X} \times [0,1]$, and λ' for the product measure on $\Omega' = [0,1]^{\tilde{X}}$. Let $\tilde{\nu}$, ν' be the Poisson point processes on $\tilde{X}$, X' respectively with density γ. For $T \subseteq \tilde{X}$

define $\psi_T : \Omega' \to \mathcal{P}X'$ by setting $\psi_T(z) = \{(t, z(t)) : t \in T\}$ for $z \in \Omega'$; let ν'_T be the image measure $\lambda'\psi_T^{-1}$ on $\mathcal{P}X'$. Then $\langle \nu'_T \rangle_{T \subseteq \tilde{X}}$ is a disintegration of ν' over $\tilde{\nu}$ (definition: 452E).

proof (a) Let $E \subseteq X'$ be a measurable set with finite measure, and write $H_E = \{S : S \cap E \neq \emptyset\}$. Then $\nu' H_E = 1 - e^{-\gamma\mu' E} \leq \gamma\mu' E$; but also $\overline{\int} \nu'_T(H_E)\tilde{\nu}(dT) \leq 2\gamma\mu' E$. **P** We know that $\int \mu_L E[\{t\}]\tilde{\mu}(dt) = \mu' E$ (252D). Let $Y \subseteq \tilde{X}$ be a conegligible set such that $E[\{t\}]$ is measurable for every $t \in Y$ and $t \mapsto \mu_L E[\{t\}] : Y \to [0,1]$ is measurable. Set $F_i = \{t : t \in Y,\ 2^{-i-1} < \mu_L E[\{t\}] \leq 2^{-i}\}$ for each $i \in \mathbb{N}$; let $\langle F'_i \rangle_{i \in \mathbb{N}}$ be a sequence of sets of finite measure with union $\tilde{X} \setminus \bigcup_{i \in \mathbb{N}} F_i$. Let W be the set of those $T \subseteq \tilde{X}$ such that $T \cap (\tilde{X} \setminus Y)$ is empty and $T \cap F_i$, $T \cap F'_i$ are finite for every $i \in \mathbb{N}$; then W is $\tilde{\nu}$-conegligible.

For any $T \in W$,

$$\begin{aligned}\psi_T^{-1}[H_E] &= \{z : \psi_T(z) \cap E \neq \emptyset\} \\ &= \bigcup_{i \in \mathbb{N}} \bigcup_{t \in T \cap F_i} \{z : z(t) \in E[\{t\}]\} \cup \bigcup_{i \in \mathbb{N}} \bigcup_{t \in T \cap F'_i} \{z : z(t) \in E[\{t\}]\}\end{aligned}$$

is measured by λ' and has measure at most $\sum_{i=0}^{\infty} 2^{-i} \#(T \cap F_i)$, because $\mu_L E[\{t\}]$ has measure at most 2^{-i} if $t \in T \cap F_i$, and is zero if $t \in T \cap F'_i$. So

$$\begin{aligned}\overline{\int} \nu'_T(H_E)\tilde{\nu}(dT) &= \overline{\int} \lambda'\psi_T^{-1}[H_E]\tilde{\nu}(dT) \leq \int \sum_{i=0}^{\infty} 2^{-i} \#(T \cap F_i)\tilde{\nu}(dT) \\ &= \sum_{i=0}^{\infty} 2^{-i} \int \#(T \cap F_i)\tilde{\nu}(dT) = \sum_{i=0}^{\infty} 2^{-i}\gamma\tilde{\mu}F_i\end{aligned}$$

(because $T \mapsto \#(T \cap F_i)$ has expectation $\gamma\tilde{\mu}F_i$)

$$\leq 2\gamma \int \mu_L E[\{t\}]\tilde{\nu}(dt) = 2\gamma\mu' E. \ \textbf{Q}$$

(b) Suppose that $\langle F_j \rangle_{j<s}$, $\langle C_{ij} \rangle_{i<r, j<s}$ and $\langle n_{ij} \rangle_{i<r, j<s}$ are such that
r, $s \in \mathbb{N}$,
$n_{ij} \in \mathbb{N}$ for $i < r$, $j < s$,
$\langle F_j \rangle_{j<s}$ is a disjoint family of subsets of $\tilde{X}$ with finite measure,
for each $j < s$, $\langle C_{ij} \rangle_{i<r}$ is a disjoint family of measurable subsets of $[0,1]$.
Set $E_{ij} = F_j \times C_{ij}$ for $i < r$ and $j < s$, and $H = \{S : S \subseteq X',\ \#(S \cap E_{ij}) = n_{ij}$ for every $i < r$, $j < s\}$. Then $\int \nu'_T(H)\tilde{\nu}(dT) = \nu' H$.

P (i) To begin with, suppose that $\bigcup_{i<r} C_{ij} = [0,1]$ for every j. Set $n_j = \sum_{i=0}^{r-1} n_{ij}$ for each j, and let W be the set of those $T \subseteq \tilde{X}$ such that $\#(T \cap F_j) = n_j$ for every j. Then $\tilde{\nu}W = \prod_{j=0}^{s-1} \frac{(\gamma\tilde{\mu}F_j)^{n_j}}{n_j!} e^{-\gamma\tilde{\mu}F_j}$. If $T \subseteq \tilde{X}$ and $z \in \psi_T^{-1}[H]$, then for each $j < s$ we must have

$$\begin{aligned}\#(T \cap F_j) &= \#(\{t : t \in T \cap F_j,\ z(t) \in \bigcup_{i<r} C_{ij}\}) \\ &= \sum_{i=0}^{r-1} \#(\{t : t \in T \cap F_j,\ z(t) \in C_{ij}\}) \\ &= \sum_{i=0}^{r-1} \#(\psi_T(z) \cap E_{ij}) = \sum_{i=0}^{r-1} n_{ij} = n_j.\end{aligned}$$

Turning this round, we see that if $T \notin W$ then $\psi_T^{-1}[H] = \emptyset$ and $\nu'_T H = 0$.

If $T \in W$, let Q be the set of all $q = \langle q(i,j) \rangle_{i<r, j<s}$ such that $\langle q(i,j) \rangle_{i<r}$ is a disjoint family of subsets of $T \cap F_j$ for each j and $\#(q(i,j)) = n_{ij}$ for all i and j. Then $\#(Q) = \prod_{j=0}^{s-1} \frac{n_j!}{\prod_{i=0}^{r-1} n_{ij}!}$. Accordingly

$$\begin{aligned}\nu'_T H &= \lambda'\{z : \psi_T(z) \in H\}\\ &= \lambda'\{z : \#(\{t : t \in T \cap F_j,\, z(t) \in C_{ij}\}) = n_{ij} \text{ for all } i,\, j\}\\ &= \sum_{q\in Q} \lambda\{z : z(t) \in C_{ij} \text{ whenever } i < r,\, j < s,\, t \in q(i,j)\}\\ &= \sum_{q\in Q} \prod_{\substack{i<r, j<s\\ t\in q(i,j)}} \mu_L C_{ij} = \sum_{q\in Q} \prod_{i<r, j<s} (\mu_L C_{ij})^{n_{ij}} = \prod_{j=0}^{s-1}(n_j! \prod_{i=0}^{r-1} \frac{(\mu_L C_{ij})^{n_{ij}}}{n_{ij}!}).\end{aligned}$$

It follows that

$$\begin{aligned}\int \nu'_T(H)\tilde\nu(dT) &= \tilde\nu W \cdot \prod_{j=0}^{s-1}(n_j! \prod_{i=0}^{r-1} \frac{(\mu_L C_{ij})^{n_{ij}}}{n_{ij}!})\\ &= \prod_{j=0}^{s-1} \frac{(\gamma\tilde\mu F_j)^{n_j}}{n_j!} e^{-\gamma\tilde\mu F_j} \cdot \prod_{j=0}^{s-1}(n_j! \prod_{i=0}^{r-1} \frac{(\mu_L C_{ij})^{n_{ij}}}{n_{ij}!})\\ &= \prod_{j=0}^{s-1} (\gamma\tilde\mu F_j)^{n_j} e^{-\gamma\tilde\mu F_j} \prod_{i=0}^{r-1} \frac{(\mu_L C_{ij})^{n_{ij}}}{n_{ij}!}\\ &= \prod_{j=0}^{s-1}\prod_{i=0}^{r-1} e^{-\gamma\mu' E_{ij}} \frac{(\gamma\mu' E_{ij})^{n_{ij}}}{n_{ij}!} = \nu' H,\end{aligned}$$

as required.

(ii) For the general case, set $C_{rj} = [0,1] \setminus \bigcup_{i<r} C_{ij}$, $E_{rj} = F_j \times C_{rj}$ for each $j < s$. For $\sigma \in \mathbb{N}^s$, set $H_\sigma = \{S : S \in H,\, \#(S \cap E_{rj}) = \sigma(j) \text{ for every } j < s\}$; then (i) tells us that $\nu' H_\sigma = \int \nu'_T(H_\sigma)\tilde\nu(dT)$ for every σ, so that

$$\nu' H = \textstyle\sum_{\sigma\in\mathbb{N}^s} \nu' H_\sigma = \sum_{\sigma\in\mathbb{N}^s} \int \nu'_T(H_\sigma)\tilde\nu(dT) = \int \nu'_T(H)\tilde\nu(dT),$$

as required. **Q**

(c) Suppose that $\langle E_i\rangle_{i<r}$ is a disjoint family in $\tilde\Sigma \otimes \Sigma_L$ such that all the projections of the E_i onto $\tilde X$ have finite measure, and $n_i \in \mathbb{N}$ for each $i < r$. Set $H = \{S : S \subseteq X',\, \#(S \cap E_i) = n_i \text{ for every } i < r\}$. Then $\int \nu'_T(H)\tilde\nu(dT) = \nu' H$.

P Let $\mathcal{E}$ be a finite subalgebra of $\tilde\Sigma$ such that every E_i belongs to $\mathcal{E} \otimes \Sigma_L$, and let $\langle F_j\rangle_{j<s}$ enumerate the atoms of $\mathcal{E}$ of finite measure; extend this to an enumeration $\langle F_j\rangle_{j<s'}$ of all the atoms of $\mathcal{E}$. Then we can express each E_i as $\bigcup_{j<s'} F_j \times C_{ij}$ where each $C_{ij} \in \Sigma_L$; but as the projection of E_i has finite measure, C_{ij} must be empty for every $j \geq s$, so $E_i = \bigcup_{j<s} F_j \times C_{ij}$. Let Q be the set of all $q \in \mathbb{N}^{r\times s}$ such that $\sum_{j=0}^{s-1} q(i,j) = n_i$ for every $i < r$. For $q \in Q$ set

$$H_q = \{S : S \subseteq X',\, \#(S \cap (F_j \times C_{ij})) = q(i,j) \text{ for every } i < r,\, j < s\}.$$

Then $\langle H_q\rangle_{q\in Q}$ is disjoint and has union H, so

$$\textstyle\int \nu'_T(H)\tilde\nu(dT) = \sum_{q\in Q} \int \nu'_T(H_q)\tilde\nu(dT) = \sum_{q\in Q} \nu' H_q = \nu' H,$$

using (b) for the middle equality. **Q**

(d) Now let $\langle E_i\rangle_{i<r}$ be a finite disjoint family of subsets of X' of finite measure, and $\langle n_i\rangle_{i<r}$ a family in $\mathbb{N}$. Set $H = \{S : S \subseteq X',\, \#(S \cap E_i) = n_i \text{ for every } i < r\}$. Then $\int \nu'_T(H)\tilde\nu(dT)$ is defined and equal to $\nu' H$.

P Let $\epsilon > 0$. For each $i < r$ we can find an $E'_i \in \tilde\Sigma \otimes \Sigma_L$ such that $\mu'(E_i \triangle E'_i) \leq \epsilon$ (251Ie). Discarding a negligible set from E'_i if necessary, we may suppose that the projection of E'_i on $\tilde X$ has finite measure. Set $\hat E_i = E'_i \setminus \bigcup_{k<i} E'_k$ for each i, so that $\langle \hat E_i\rangle_{i<r}$ is a disjoint family in $\tilde\Sigma \otimes \Sigma_L$, and the projections of the $\hat E_i$

are still of finite measure. Set $\hat{H} = \{S : S \subseteq X', \#(S \cap \hat{E}_i) = n_i \text{ for every } i < r\}$. Then (c) tells us that $\int \nu'_T(\hat{H})\tilde{\nu}(dT) = \nu'\hat{H}$.

Set $E = \bigcup_{i<r}(E_i \triangle E'_i)$. Then $\mu' E \leq r\epsilon$, while E includes $E_i \triangle \hat{E}_i$ for every i, so

$$\hat{H} \setminus H_E \subseteq H \subseteq \hat{H} \cup H_E,$$

where $H_E = \{S : S \cap E \neq \emptyset\}$ as in (a). Accordingly

$$\begin{aligned}
\nu'H - 3r\gamma\epsilon &\leq \nu'\hat{H} - 2r\gamma\epsilon \\
&\text{(by (a))} \\
&= \int \nu'_T(\hat{H})\tilde{\nu}(dT) - 2r\gamma\epsilon \\
&\text{(by (c))} \\
&\leq \int \nu'_T(\hat{H}) - \nu'_T(H_E)\tilde{\nu}(dT) \\
&\text{(by the other part of (a))} \\
&\leq \underline{\int}(\nu'_T)_*(H)\tilde{\nu}(dT) \leq \overline{\int}(\nu'_T)^*(H)\tilde{\nu}(dT) \\
&\leq \overline{\int} \nu'_T(\hat{H}) + \nu'_T(H_E)\tilde{\nu}(dT) \leq \nu'\hat{H} + 2r\gamma\epsilon \leq \nu'H + 3r\gamma\epsilon.
\end{aligned}$$

As ϵ is arbitrary,

$$\nu'H = \underline{\int}(\nu'_T)_*(H)\tilde{\nu}(dT) = \overline{\int}(\nu'_T)^*(H)\tilde{\nu}(dT).$$

In particular, $(\nu'_T)_*(H) = (\nu'_T)^*(H)$ for almost every T; since ν'_T is the image of the complete measure λ, it is complete (212Bd), and H is measured by almost every ν'_T; finally, $\int \nu'_T(H)\tilde{\nu}(dT)$ is defined and equal to $\nu'H$. **Q**

(e) So if we write $\mathcal{H}$ for the family of subsets H of $\mathcal{P}X'$ such that $\int \nu'_T(H)\tilde{\nu}(dT)$ is defined and equal to $\nu'H$, and $\mathcal{H}_0$ for the family of sets of the form $H = \{S : S \subseteq X', \#(S \cap \hat{E}_i) = n_i \text{ for every } i < r\}$ where $\langle E_i\rangle_{i<r}$ is a disjoint family of sets of finite measure and $n_i \in \mathbb{N}$ for $i < r$, we have $\mathcal{H} \supseteq \mathcal{H}_0$. But $\mathcal{H}$ is a Dynkin class, so includes the σ-algebra T generated by $\mathcal{H}_0$, by 495C. Since every ν'-negligible set is included in a ν'-negligible member of T′, $\mathcal{H}$ contains every ν'-negligible set, and therefore every set measured by ν'; which is what we need to know.

495I Theorem Let (X, Σ, μ) and $(\tilde{X}, \tilde{\Sigma}, \tilde{\mu})$ be atomless σ-finite measure spaces and $\gamma > 0$. Let ν, $\tilde{\nu}$ be the Poisson point processes on X, $\tilde{X}$ respectively with density γ. Suppose that $f : X \to \tilde{X}$ is inverse-measure-preserving and that $\langle\mu_t\rangle_{t\in\tilde{X}}$ is a disintegration of μ over $\tilde{\mu}$ consistent with f (definition: 452E) such that every μ_t is a probability measure. Write λ for the product measure $\prod_{t\in\tilde{X}} \mu_t$ on $\Omega = X^{\tilde{X}}$, and for $T \subseteq \tilde{X}$ define $\phi_T : \Omega \to \mathcal{P}X$ by setting $\phi_T(z) = z[T]$ for $z \in \Omega$; let ν_T be the image measure $\lambda\phi_T^{-1}$ on $\mathcal{P}X$. Then $\langle\nu_T\rangle_{T\subseteq\tilde{X}}$ is a disintegration of ν over $\tilde{\nu}$. Moreover

(i) setting $\tilde{f}(S) = f[S]$ for $S \subseteq X$, $\langle\nu_T\rangle_{T\subseteq\tilde{X}}$ is consistent with $\tilde{f} : \mathcal{P}X \to \mathcal{P}\tilde{X}$;

(ii) if μ is strongly consistent with f, then $\langle\nu_T\rangle_{T\subseteq\tilde{X}}$ is strongly consistent with $\tilde{f}$.

proof (a) For $T \subseteq \tilde{X}$ let V_T be the set of those $z \in \Omega$ such that $fz\restriction T$ is injective. We need to know that

$$W = \{T : T \subseteq \tilde{X}, T \text{ is countable}, V_T \text{ is } \lambda\text{-conegligible}\}$$

is $\tilde{\nu}$-conegligible. **P** Write $\tilde{\Sigma}^f = \{F : F \in \tilde{\Sigma}, \tilde{\mu}F < \infty\}$. Because $\tilde{\mu}$ is atomless and σ-finite, there is a countable subalgebra $\mathcal{E}$ of $\tilde{\Sigma}$ such that for every $\epsilon > 0$ there is a cover of $\tilde{X}$ by members of $\mathcal{E}$ of measure at most ϵ. Set

$$Y = \{t : t \in \tilde{X}, \mu_t f^{-1}[F] = (\chi F)(t) \text{ for every } F \in \mathcal{E}\},$$

so that Y is $\tilde{\mu}$-conegligible and $\mathcal{P}Y$ is $\tilde{\nu}$-conegligible. For $F \in \mathcal{E}$, let W_F be the set of those $T \subseteq Y$ such that for every $t \in T \cap F$ there is an $F' \in \mathcal{E}$ such that $T \cap F' = \{t\}$. Now, given $F \in \mathcal{E} \cap \tilde{\Sigma}^f$ and $\epsilon > 0$, there is a partition $\langle F_i \rangle_{i \in I}$ of F into members of $\mathcal{E}$ of measure at most ϵ. Then

$$\begin{aligned}\tilde{\nu}^*(\mathcal{P}Y \setminus W_F) &\leq \tilde{\nu}\{T : \#(T \cap F_i) > 1 \text{ for some } i \in I\} \\ &\leq \sum_{i \in I} 1 - e^{-\gamma\tilde{\mu}F_i}(1 + \gamma\tilde{\mu}F_i) \leq \sum_{i \in I} (\gamma\tilde{\mu}F_i)^2 \leq \epsilon\gamma^2 \sum_{i \in I} \tilde{\mu}F_i = \epsilon\gamma^2\tilde{\mu}F.\end{aligned}$$

As ϵ is arbitary, W_F is $\tilde{\nu}$-conegligible; accordingly $W' = \bigcap\{W_F : F \in \mathcal{E} \cap \tilde{\Sigma}^f\}$ is $\tilde{\nu}$-conegligible.

Now suppose that $T \in W'$. Because $\tilde{X}$ is covered by $\mathcal{E} \cap \tilde{\Sigma}^f$, we see that for every $t \in T$ there is an $F \in \mathcal{E} \cap \tilde{\Sigma}^f$ containing t, and now there is an $F' \in \mathcal{E}$ such that $T \cap F' = \{t\}$. In particular, T is countable, so

$$U_T = \{z : z(t) \in f^{-1}[F] \text{ whenever } F \in \mathcal{E} \text{ and } t \in T \cap F\}$$

is λ-conegligible. Take $z \in U_T$. If t, t' are distinct points of T, there is an $F \in \mathcal{E}$ containing t but not t', and now F contains $f(z(t))$ but not $f(z(t'))$. So $z \restriction T$ is injective. Thus $U_T \subseteq V_T$ and V_T is λ-conegligible. This is true for every $T \in W'$, so $W \supseteq W'$ is $\tilde{\nu}$-conegligible. **Q**

(b) Suppose that $\langle E_i \rangle_{i<r}$ is a disjoint family of subsets of X with finite measure, and $n_i \in \mathbb{N}$ for $i < r$. Set $H = \{S : S \subseteq X, \#(S \cap E_i) = n_i \text{ for every } i < r\}$. Then $\int \nu_T(H)\tilde{\nu}(dT)$ is defined and equal to νH. **P** As in 495H, set $X' = \tilde{X} \times [0,1]$ with the product measure μ', and write λ' for the product measure on $\Omega' = [0,1]^{\tilde{X}}$. Let ν' be the Poisson point process on X' with density γ. For $T \subseteq \tilde{X}$ define $\psi_T : \Omega' \to \mathcal{P}X'$ by setting $\psi_T(z) = \{(t, z(t)) : t \in T\}$ for $z \in \Omega'$ and let ν'_T be the image measure $\lambda\psi_T^{-1}$ on $\mathcal{P}X'$.

For each $i < r$, $\int \mu_t(E_i)\tilde{\mu}(dt) = \mu E_i$; set $Y_1 = \{t : \mu_t E_i \text{ is defined for every } i < r\}$, so that $Y_1 \subseteq \tilde{X}$ is $\tilde{\nu}$-conegligible. Set $f_i(t) = \sum_{j<i} \mu_t E_j$ for $t \in Y_1$ and $i < r$, and

$$E'_i = \{(t, \alpha) : t \in Y_1,\ f_i(t) \leq \alpha < f_{i+1}(t)\}$$

for $i < r$. Then $\mu' E'_i = \int f_{i+1} - f_i \, d\tilde{\nu} = \mu E_i$ for each i, by 252N.

Set

$$H' = \{S : S \subseteq X', \#(S' \cap E'_i) = n_i \text{ for every } i < r\},$$

$$W_1 = \{T : T \in W,\ T \subseteq Y_1,\ \nu'_T H' \text{ is defined}\},$$

so that W_1 is $\tilde{\nu}$-conegligible. Let T be any member of W_1. Let Q be the set of partitions $q = \langle q(i) \rangle_{i \leq r}$ of T such that $\#(q(i)) = n_i$ for every $i < r$; because T is countable, so is Q. Set $E_r = X \setminus \bigcup_{i<r} E_i$ and $E'_r = X' \setminus \bigcup_{i<r} E'_i$. Then $\mu_t E_r = 1 - \sum_{i=0}^{r-1} \mu_t E_i = \mu_L E'_r[\{t\}]$ for every $t \in Y_1$. Now

$$\begin{aligned}\nu'_T H' &= \lambda'\{z : z \in \Omega',\ \psi_T(z) \in H'\} \\ &= \lambda'\{z : z \in \Omega',\ \#(\{t : t \in T,\ z(t) \in E'_i[\{t\}]\}) = n_i \text{ for every } i < r\} \\ &= \sum_{q \in Q} \lambda'\{z : z \in \Omega',\ z(t) \in E'_i[\{t\}] \text{ whenever } i \leq r \text{ and } t \in q(i)\} \\ &= \sum_{q \in Q} \prod_{i=0}^{r} \prod_{t \in q(i)} \mu_L E'_i[\{t\}] \\ &= \sum_{q \in Q} \prod_{i=0}^{r} \prod_{t \in q(i)} \mu_t E_i \\ &= \sum_{q \in Q} \lambda\{z : z \in \Omega,\ z(t) \in E_i \text{ whenever } i \leq r \text{ and } t \in q(i)\} \\ &= \lambda\{z : z \in \Omega,\ \#(\{t : t \in T,\ z(t) \in E_i\}) = n_i \text{ for every } i < r\} \\ &= \lambda\{z : z \in V_T,\ \#(\{t : t \in T,\ z(t) \in E_i\}) = n_i \text{ for every } i < r\} \\ &= \lambda\{z : z \in V_T,\ \#(z[T] \cap E_i) = n_i \text{ for every } i < r\} \\ &= \lambda\{z : z \in V_T,\ \phi_T(z) \in H\} = \nu_T H.\end{aligned}$$

Since this is true for $\tilde{\nu}$-almost every T,

$$\int \nu_T(H)\tilde{\nu}(dT) = \int \nu'_T(H')\tilde{\nu}(dT) = \nu'H'$$

(495H)

$$= \prod_{i<r} \frac{(\gamma\mu' E'_i)^{n_i}}{n_i!} e^{-\gamma\mu' E'_i} = \prod_{i<r} \frac{(\gamma\mu E_i)^{n_i}}{n_i!} e^{-\gamma\mu E_i} = \nu H. \text{ Q}$$

Now, just as in part (e) of the proof of 495H, 495C tells us that $\int \nu_T(H)\tilde{\nu}(dT) = \nu H$ whenever ν measures H, so that $\langle \nu_T \rangle_{T\subseteq\tilde{X}}$ is a disintegration of ν over $\tilde{\nu}$.

(c) Let $\langle F_i \rangle_{i<r}$ be a disjoint family in $\tilde{\Sigma}^f$, and take $n_i \in \mathbb{N}$ for $i < r$. Set

$$F_r = \tilde{X} \setminus \bigcup_{i<r} F_i,$$

$$Y_2 = \{t : t \in \tilde{X},\ \mu_t f^{-1}[F_i] = (\chi F_i)(t) \text{ for every } i \leq r\},$$

$$W_2 = \{T : T \in W,\ T \subseteq Y_2\},$$

so that Y_2 is $\tilde{\mu}$-conegligible and W_2 is $\tilde{\nu}$-conegligible. Set

$$\tilde{H} = \{T : T \in W_2,\ \#(T \cap F_i) = n_i \text{ for every } i < r\}, \quad H = \tilde{f}^{-1}[\tilde{H}] = \{S : S \subseteq X,\ f[S] \in \tilde{H}\}.$$

Then $\nu_T H = \chi\tilde{H}(T)$ for every $T \in W_2 \cap \tilde{H}$. **P** For $i \leq r$ and $t \in T \cap F_i$, we have

$$\lambda\{z : z(t) \in f^{-1}[F_i]\} = \mu_t f^{-1}[F_i] = 1$$

because $T \subseteq Y_2$. So

$$V = \{z : z \in V_T,\ f(z(t)) \in F_i \text{ whenever } i \leq r \text{ and } t \in T \cap F_i\}$$

is λ-conegligible. But if $z \in V$ then $fz\restriction T$ is injective, so

$$\#(f[z[T]] \cap F_i) = \#(T \cap (fz)^{-1}[F_i]) = \#(T \cap F_i)$$

for every $i < r$, and $z[T] \in H$ iff $T \in \tilde{H}$. Thus

$$\nu_T H = \lambda\{z : z[T] \in H\} = \lambda V = 1 \text{ if } T \in \tilde{H},$$
$$= \lambda(X^{\tilde{X}} \setminus V) = 0 \text{ otherwise. } \text{Q}$$

Setting

$$\mathcal{H} = \{\tilde{H} : \tilde{H} \subseteq \tilde{X},\ \nu_T \tilde{f}^{-1}[\tilde{H}] = \chi\tilde{H}(T) \text{ for } \tilde{\nu}\text{-almost every } T \in \tilde{H}\},$$

it is easy to check that $\mathcal{H}$ is a Dynkin class containing all sets of the form $\{T : T \subseteq \tilde{X},\ \#(T \cap F_i) = n_i \text{ for every } i < r\}$ where $\langle F_i \rangle_{i<r}$ is a disjoint family in $\tilde{\Sigma}^f$, and therefore including the σ-algebra generated by such sets, by 495C. But as $\mathcal{H}$ also contains any subset of a negligible set belonging to $\mathcal{H}$ (remember that all the ν_T are complete probability measures, like λ), it includes the domain of $\tilde{\nu}$, and $\langle \nu_T \rangle_{T\subseteq\tilde{X}}$ is consistent with $\tilde{f}$.

(d) Now suppose that $\langle \mu_t \rangle_{t\in\tilde{X}}$ is strongly consistent with f. Set $Y_3 = \{t : \mu_t f^{-1}[\{t\}] = 1\}$ and $W_3 = \{T : T \in W,\ T \subseteq Y_3\}$. Then $\nu_T \tilde{f}^{-1}[\{T\}] = 1$ for every $T \in W_3$. **P** Set $V'_T = \{z : z \in X^{\tilde{X}},\ f(z(t)) = t \text{ for every } t \in T\}$. For each $t \in T$,

$$\lambda\{z : f(z(t)) = t\} = \mu_t f^{-1}[\{t\}] = 1,$$

because $T \subseteq W_3$. As T is countable, V'_T is λ-conegligible. But now

$$\nu_T \tilde{f}^{-1}[\{T\}] = \lambda\{z : f[z[T]] = T\} = \lambda V'_T = 1. \text{ Q}$$

As W_3 is $\tilde{\nu}$-conegligible, $\langle \nu_T \rangle_{T\subseteq\tilde{X}}$ is strongly consistent with $\tilde{f}$.

495J Proposition Let $(\mathfrak{A},\bar\mu)$ be a measure algebra, and $\gamma>0$. Then there are a probability algebra $(\mathfrak{B},\bar\lambda)$ and a function $\theta:\mathfrak{A}\to\mathfrak{B}$ such that

(i) $\theta(\sup A)=\sup\theta[A]$ for every non-empty $A\subseteq\mathfrak{A}$ such that $\sup A$ is defined in $\mathfrak{A}$;

(ii) $\bar\lambda\theta(a)=1-e^{-\gamma\bar\mu a}$ for every $a\in\mathfrak{A}$, interpreting $e^{-\infty}$ as 0;

(iii) whenever $\langle a_i\rangle_{i\in I}$ is a disjoint family in $\mathfrak{A}$ and $\mathfrak{C}_i$ is the closed subalgebra of $\mathfrak{B}$ generated by $\{\theta(a):a\subseteq a_i\}$ for each i, then $\langle\mathfrak{C}_i\rangle_{i\in I}$ is stochastically independent.

proof (a) We may suppose that $(\mathfrak{A},\bar\mu)$ is the measure algebra of a measure space (X,Σ,μ) (321J). Set $\Sigma^f=\{E:E\in\Sigma,\ \mu E<\infty\}$ and $\mathfrak{A}^f=\{a:a\in\mathfrak{A},\ \bar\mu a<\infty\}$. Let (Ω,Λ,λ) and $\langle g_E\rangle_{E\in\Sigma^f}$ be as in 495B, and take $(\mathfrak{B},\bar\lambda)$ to be the measure algebra of (Ω,Λ,λ). Note that if E, $F\in\Sigma^f$ and $\mu(E\triangle F)=0$, then $g_{E\setminus F}$ and $g_{F\setminus E}$ have Poisson distributions with expectation 0, so are zero almost everywhere, while $g_E=_{\text{a.e.}}g_{E\cap F}+g_{E\setminus F}$ and $g_F=_{\text{a.e.}}g_{E\cap F}+g_{F\setminus E}$; so that $g_E=_{\text{a.e.}}g_F$. This means that we can define $\theta:\mathfrak{A}^f\to\mathfrak{B}$ by setting $\theta(E^\bullet)=\{\omega:g_E(\omega)\neq0\}^\bullet$ whenever $E\in\Sigma^f$, and we shall have $\bar\lambda(\theta a)=1-e^{-\gamma\bar\mu a}$ because g_E has a Poisson distribution with expectation $\bar\mu a$ whenever $E\in\Sigma^f$ and $E^\bullet=a$. For $a\in\mathfrak{A}\setminus\mathfrak{A}^f$ set $\theta(a)=1_{\mathfrak{B}}$.

(b) If a, $b\in\mathfrak{A}^f$ are disjoint, they can be represented as $E^\bullet$, $F^\bullet$ where E, $F\in\Sigma^f$ are disjoint. In this case, $g_{E\cup F}=_{\text{a.e.}}g_E+g_F$, so $\theta(a\cup b)=\theta(a)\cup\theta(b)$. Of course the same is true if a, $b\in\mathfrak{A}$ are disjoint and either has infinite measure. It follows at once that for any a, $b\in\mathfrak{A}$,

$$\theta(a\cup b)=\theta(a\setminus b)\cup\theta(a\cap b)\cup\theta(b\setminus a)=\theta(a)\cup\theta(b).$$

Consequently $\theta(\sup A)=\sup\theta[A]$ for any finite set $A\subseteq\mathfrak{A}$. If $A\subseteq\mathfrak{A}$ is an infinite set with supremum a^*, then $A'=\{\sup B:B\in[A]^{<\omega}\}$ is an upwards-directed set with supremum a^*, so there is a non-decreasing sequence $\langle a_n\rangle_{n\in\mathbb{N}}$ in A' such that $\lim_{n\to\infty}\bar\mu a_n=\bar\mu a^*$ (321D). In this case, $b^*=\sup_{n\in\mathbb{N}}\theta(a_n)$ is defined in $\mathfrak{B}$ and

$$\bar\lambda b^*=\lim_{n\to\infty}\bar\lambda\theta(a_n)=\lim_{n\to\infty}1-e^{-\gamma\bar\mu a_n}=1-e^{-\gamma\bar\mu a^*}=\bar\lambda\theta(a^*).$$

So $b^*=\theta(a^*)$; since $\theta(a^*)$ is certainly an upper bound of $\theta[A']$, it must actually be the supremum of $\theta[A']$ and therefore (because θ preserves finite suprema) of $\theta[A]$.

(c) Thus θ satisfies (i) and (ii). As for (iii), note first that if $\langle a_i\rangle_{i\in I}$ is a finite disjoint family in $\mathfrak{A}$, then $\bar\lambda(\inf_{i\in I}\theta(a_i))=\prod_{i\in I}\bar\lambda\theta(a_i)$. **P** Set $J=\{i:i\in I,\ \bar\mu a_i<\infty\}$. For $i\in J$, represent a_i as $E_i^\bullet$ where $\langle E_i\rangle_{i\in J}$ is a disjoint family in Σ^f. Then $\langle g_{E_i}\rangle_{i\in J}$ is independent, so

$$\begin{aligned}\bar\lambda(\inf_{i\in I}\theta(a_i))&=\bar\lambda(\inf_{i\in J}\theta(a_i))=\lambda(\Omega\cap\bigcap_{i\in J}\{\omega:g_{E_i}(\omega)=0\})\\&=\prod_{i\in J}\lambda\{\omega:g_{E_i}(\omega)=0\}=\prod_{i\in J}\bar\lambda\theta(a_i)=\prod_{i\in I}\bar\lambda\theta(a_i).\ \textbf{Q}\end{aligned}$$

Now suppose that $\langle a_i\rangle_{i\in I}$ is a finite disjoint family in $\mathfrak{A}$ and that $\mathfrak{D}_i$ is the subalgebra of $\mathfrak{B}$ generated by $D_i=\{\theta(a):a\subseteq a_i\}$ for each i. We know that each D_i is closed under $\cup$ (by (i)) and that $\bar\lambda(\inf_{i\in J}d_i)=\prod_{i\in J}\bar\lambda d_i$ whenever $J\subseteq I$ and $d_i\in D_i$ for each $i\in J$, that is, that $\langle d_i\rangle_{i\in I}$ is stochastically independent whenever $d_i\in D_i$ for each i. Setting $D_i'=\{1\setminus d:d\in D_i\}\cup\{0\}$, we see that D_i' is closed under $\cap$ and that $\langle d_i\rangle_{i\in I}$ is stochastically independent whenever $d_i\in D_i'$ for each i (as in 272F). An induction on $\#(J)$, using 313Ga for the inductive step, shows that if $J\subseteq I$, $d_i\in\mathfrak{D}_i$ for $i\in J$, and $d_i\in D_i'$ for $i\in I\setminus J$, then $\bar\lambda(\inf_{i\in I}d_i)=\prod_{i\in I}\bar\lambda d_i$. At the end of the induction, we see that $\bar\lambda(\inf_{i\in I}d_i)=\prod_{i\in I}\bar\lambda d_i$ whenever $d_i\in\mathfrak{D}_i$ for each i, and therefore whenever d_i belongs to the topological closure of $\mathfrak{D}_i$ for each i, where $\mathfrak{B}$ is given its measure-algebra topology (§323).

Finally, suppose that $\langle a_i\rangle_{i\in I}$ is any disjoint family in $\mathfrak{A}$, and $\mathfrak{C}_i$ is the closed subalgebra of $\mathfrak{B}$ generated by $D_i=\{\theta(a):a\subseteq a_i\}$ for each i. Take a finite set $J\subseteq I$ and $c_i\in\mathfrak{C}_i$ for each $i\in J$. By 323J, $\mathfrak{C}_i$ is the topological closure of the subalgebra $\mathfrak{D}_i$ of $\mathfrak{B}$ generated by $\{\theta(a):a\subseteq a_i\}$; so $\bar\lambda(\inf_{i\in J}c_i)=\prod_{i\in J}\bar\lambda c_i$. As $\langle c_i\rangle_{i\in J}$ is arbitrary, $\langle\mathfrak{C}_i\rangle_{i\in I}$ is independent.

495K Proposition Let U be any L-space. Then there are a probability space (Ω,Λ,λ) and a positive linear operator $T:U\to L^1(\lambda)$ such that $\|Tu\|_1=\|u\|_1$ whenever $u\in L^1(\mu)^+$ and $\langle Tu_i\rangle_{i\in I}$ is stochastically independent in $L^0(\lambda)$ whenever $\langle u_i\rangle_{i\in I}$ is a disjoint family in $L^1(\mu)$.

Remarks Recall that a family $\langle u_i\rangle_{i\in I}$ in a Riesz space is 'disjoint' if $|u_i|\wedge|u_j|=0$ for all distinct i, $j\in I$ (352C). A family $\langle v_i\rangle_{i\in I}$ in $L^0(\lambda)$ is 'independent' if $\langle g_i\rangle_{i\in I}$ is an independent family of random variables whenever $g_i\in\mathcal{L}^0(\lambda)$ represents v_i for each i; compare 367W.

proof (a) By Kakutani's theorem, there is a measure algebra $(\mathfrak{A},\bar\mu)$ such that U is isomorphic, as Banach lattice, to $L^1(\mathfrak{A},\bar\mu)$; now $(\mathfrak{A},\bar\mu)$ can be represented as the measure algebra of a measure space (X,Σ,μ), and we can identify U and $L^1(\mathfrak{A},\bar\mu)$ with $L^1(\mu)$ (365B). Set $\Sigma^f=\{E:E\in\Sigma,\ \mu E<\infty\}$ and $\mathfrak{A}^f=\{a:a\in\mathfrak{A},\ \bar\mu a<\infty\}$ as usual. Take (Ω,Λ,λ) and $\langle g_E\rangle_{E\in\Sigma^f}$ from 495B, with $\gamma=1$. As in the proof of 495J, we have $g_E=_{\text{a.e.}}g_F$ whenever E, $F\in\Sigma^f$ and $\mu(E\triangle F)=0$; consequently we can define $\psi:\mathfrak{A}^f\to L^1(\lambda)$ by setting $\psi a=g_E^\bullet$ whenever $E\in\Sigma^f$ and $E^\bullet=a$. Again as in 495J, $g_{E\cup F}=_{\text{a.e.}}g_E+g_F$ whenever E, $F\in\Sigma^f$ are disjoint, so ψ is additive. Also

$$\|\psi a\|_1=\int g_E\,d\lambda=\mu E=\bar\mu a$$

whenever $E\in\Sigma^f$ represents $a\in\mathfrak{A}^f$. By 365I, there is a unique bounded linear operator $T:L^1(\mathfrak{A},\bar\mu)\to L^1(\lambda)$ such that $T(\chi a)=\psi a$ for every $a\in\mathfrak{A}^f$. By 365Ka, T is a positive operator. The set $\{u:u\in L^1(\mathfrak{A},\bar\mu)^+,\|Tu\|_1=\|u\|_1\}$ is closed under addition, norm-closed and contains $\alpha\chi a$ for every $a\in\mathfrak{A}^f$ and $\alpha\geq0$, so is the whole of $L^1(\mathfrak{A},\bar\mu)^+$, by 365F.

(b) Now let $\langle u_i\rangle_{i\in I}$ be a disjoint family in $L^1(\mathfrak{A},\bar\mu)$. Then $\langle Tu_i\rangle_{i\in I}$ is independent. **P?** Otherwise, there are a finite set $J\subseteq I$ and a family $\langle V_i\rangle_{i\in J}$ such that V_i is a neighbourhood of Tu_i in the topology of convergence in measure on $L^0(\mu)$ for each $i\in J$, and $\langle v_i\rangle_{i\in J}$ is not independent whenever $v_i\in V_i$ for each i (367W). Because the embedding $L^1(\lambda)\subseteq L^0(\lambda)$ is continuous for the norm topology on $L^1(\lambda)$ and the topology of convergence in measure (245G), there is a $\delta>0$ such that $Tu_i'\in V_i$ whenever $i\in J$, $u_i'\in L^1(\mathfrak{A},\bar\mu)$ and $\|u_i'-u_i\|_1\leq\delta$. Now we can find such $u_i'\in S(\mathfrak{A}^f)$ with $|u_i'|\leq|u_i|$ (365F).

Express each u_i' as $\sum_{k=0}^{n_i}\alpha_{ik}\chi a_{ik}$ where $\langle a_{ik}\rangle_{k\leq n_i}$ is a disjoint family in $\mathfrak{A}^f$ and no α_{ik} is zero (361Eb). In this case, all the a_{ik}, for $i\in J$ and $k\leq n_i$, are disjoint, so all the $\psi(a_{ik})$ are independent. But this means that $\langle Tu_i'\rangle_{i\in J}=\langle\sum_{k=0}^{n_i}\alpha_{ik}\psi(a_{ik})\rangle_{i\in J}$ is independent (272K); which is impossible, because $Tu_i'\in V_i$ for every $i\in J$. **XQ**

So T, regarded as a function from U to $L^1(\lambda)$, has the required properties.

495L The following is a more concrete expression of the same ideas.

Proposition Let (X,Σ,μ) be an atomless measure space, and ν the Poisson point process on X with density $\gamma>0$.

(a) If $h\in\mathcal{L}^1(\mu)$, $Q_h(S)=\sum_{x\in S\cap\operatorname{dom}h}h(x)$ is defined for ν-almost every $S\subseteq X$, and $\int Q_h\,d\nu=\gamma\int h\,d\mu$.

(b) We have a positive linear operator $T:L^1(\mu)\to L^1(\nu)$ defined by setting $T(h^\bullet)=Q_h^\bullet$ for every $h\in\mathcal{L}^1(\mu)$.

(c) $\|Tu\|_1=\gamma\|u\|_1$ whenever $u\in L^1(\mu)^+$ and $\langle Tu_i\rangle_{i\in I}$ is stochastically independent in $L^0(\lambda)$ whenever $\langle u_i\rangle_{i\in I}$ is a disjoint family in $L^1(\mu)$.

proof (a) In the language of 495D, $Q_{\chi E}=f_E$ for every $E\in\Sigma^f$. So $Q_{\chi E}\in\mathcal{L}^1(\nu)$ and $\int Q_{\chi E}\,d\nu=\gamma\mu E$ for every $E\in\Sigma^f$. If $h=\sum_{i=0}^r\alpha_i\chi E_i$ is a simple function on X, then $Q_h=_{\text{a.e.}}\sum_{i=0}^r\alpha_iQ_{\chi E_i}\in\mathcal{L}^1(\nu)$ and $\int Q_h\,d\nu=\int h\,d\mu$. If $h\in\mathcal{L}^1(\mu)$ is zero a.e., then $\{S:S\subseteq h^{-1}[\{0\}]\}$ is ν-conegligible, so $Q_h=0$ a.e. It follows that if $h\in\mathcal{L}^1(\mu)$ is non-negative, and $\langle h_n\rangle_{n\in\mathbb{N}}$ is a non-decreasing sequence of simple functions converging to h almost everywhere, then $Q_h=_{\text{a.e.}}\lim_{n\to\infty}Q_{h_n}$, while $Q_{h_n}\leq_{\text{a.e.}}Q_{h_{n+1}}$ for every n; so Q_h is ν-integrable and

$$\int Q_h\,d\nu=\lim_{n\to\infty}\int Q_{h_n}\,d\nu=\lim_{n\to\infty}\gamma\int h_n\,d\mu=\gamma\int h\,d\mu.$$

(b) Since $Q_h=_{\text{a.e.}}Q_{h'}$ whenever $h=_{\text{a.e.}}h'$ in $\mathcal{L}^1(\mu)$, we can define $T:L^1(\mu)\to L^1(\nu)$ by setting $T(h^\bullet)=(Q_h)^\bullet$ for every $h\in\mathcal{L}^1(\mu)$; because $Q_{\alpha h}=_{\text{a.e.}}\alpha Q_h$ and $Q_{h+h'}=_{\text{a.e.}}Q_h+Q_{h'}$ whenever h, $h'\in\mathcal{L}^1(\mu)$ and $\alpha\in\mathbb{R}$, T is linear; because $Q_h\geq0$ a.e. whenever $h\geq0$ a.e., T is positive.

(c) Because $\int Q_h\,d\nu=\gamma\int h\,d\mu$ for every $h\in\mathcal{L}^1(\mu)$, and T is positive, $\|Tu\|_1=\gamma\|u\|_1$ for every $u\in L^1(\mu)^+$. Finally, if $\langle u_i\rangle_{i\in I}$ is a finite disjoint family in $L^1(\mu)$, we can find a family $\langle h_i\rangle_{i\in I}$ of measurable functions from X to $\mathbb{R}$ such that $h_i^\bullet=u_i$ for each i and the sets $E_i=\{x:h_i(x)\neq0\}$ are disjoint. For each $i\in I$, let T_i be the σ-algebra of subsets of $\mathcal{P}X$ generated by sets of the form $\{S:\#(S\cap E)=n\}$ where

$E \subseteq E_i$ has finite measure and $n \in \mathbb{N}$. Then $\langle \mathrm{T}_i \rangle_{i\in I}$ is independent (as in part (c) of the proof of 495J), and each Q_{h_i} is T_i-measurable, so $\langle Q_{h_i}\rangle_{i\in I}$ is independent and $\langle Tu_i\rangle_{i\in I}$ is independent.

495M We can identify the characteristic functions of the random variables Q_f as defined above.

Proposition Let (X, Σ, μ) be an atomless measure space, and ν the Poisson point process on X with density $\gamma > 0$. For $f \in \mathcal{L}^1(\mu)$ set $Q_f(S) = \sum_{x\in S\cap \mathrm{dom}\, f} f(x)$ when $S \subseteq X$ and the sum is defined in $\mathbb{R}$. Then

$$\int_{\mathcal{P}X} e^{iyQ_f}\, d\nu = \exp\big(\gamma \int_X (e^{iyf} - 1) d\mu\big)$$

for any $y \in \mathbb{R}$.

proof Note that Q_f is defined ν-almost everywhere, by 495La.

(a) Consider first the case in which f is a simple function, expressed as $\sum_{j=0}^n \alpha_j \chi F_j$ where $\langle F_j\rangle_{j\le n}$ is a disjoint family of sets of finite measure and $\alpha_j \in \mathbb{R}$ for each j. Then $Q_f(S) = \sum_{j=0}^n \alpha_j \#(S \cap F_j)$ for ν-almost every S, so

$$\int e^{iyQ_f}\, d\nu = \int \prod_{j=0}^n e^{iy\alpha_j \#(S\cap F_j)} \nu(dS) = \prod_{j=0}^n \int e^{iy\alpha_j \#(S\cap F_j)} \nu(dS)$$

(because the functions $S \mapsto \#(S \cap F_j)$ are independent)

$$\begin{aligned} &= \prod_{j=0}^n \sum_{k=0}^\infty \frac{(\gamma\mu F_j)^k}{k!} e^{-\gamma\mu F_j} e^{iy\alpha_j k} = \prod_{j=0}^n e^{-\gamma\mu F_j} \sum_{k=0}^\infty \frac{(e^{iy\alpha_j}\gamma\mu F_j)^k}{k!} \\ &= \prod_{j=0}^n \exp\big((e^{iy\alpha_j} - 1)\gamma\mu F_j\big) = \exp\big(\gamma \sum_{j=0}^n (e^{iy\alpha_j} - 1)\mu F_j\big) \\ &= \exp\big(\gamma \int (e^{iyf} - 1) d\mu\big). \end{aligned}$$

(b) Now suppose that f is any integrable function. Then there is a sequence $\langle f_n\rangle_{n\in\mathbb{N}}$ of simple functions such that $|f_n| \le_{\text{a.e.}} |f|$ for every n and $\lim_{n\to\infty} f_n =_{\text{a.e.}} f$. Write q_n, q for Q_{f_n}, Q_f. Set

$$D = \{x : x \in \mathrm{dom}\, f,\ |f_n(x)| \le |f(x)| \text{ for every } n \text{ and } \lim_{n\to\infty} f_n(x) = f(x)\},$$

so that D is μ-conegligible. If $S \subseteq D$ and $Q_{|f|}(S)$ is defined, then $q(S) = \lim_{n\to\infty} q_n(S)$, and this is true for ν-almost every S; so $\int e^{iyq} d\nu = \lim_{n\to\infty} e^{iyq_n} d\nu$, by Lebesgue's Dominated Convergence Theorem. On the other hand,

$$|e^{i\alpha} - 1| = |\textstyle\int_0^\alpha \frac{1}{i} e^{it} dt| \le \alpha, \quad |e^{-i\alpha} - 1| = |\int_0^\alpha \frac{1}{i} e^{-it} dt| \le \alpha$$

for every $\alpha \ge 0$. So if we set $g(x) = e^{iyf(x)} - 1$, $g_n(x) = e^{iyf_n(x)} - 1$ when these are defined, we have $|g_n| \le_{\text{a.e.}} |yf_n| \le_{\text{a.e.}} |yf|$ for every n. Accordingly

$$\textstyle\int (e^{iyf} - 1) d\mu = \int \lim_{n\to\infty} (e^{iyf_n} - 1) d\mu = \lim_{n\to\infty} \int (e^{iyf_n} - 1) d\mu$$

by Lebesgue's theorem again. It follows that

$$\int e^{iyQ_f}\, d\nu = \lim_{n\to\infty} \int e^{iyq_n} d\nu = \lim_{n\to\infty} \exp\big(\gamma \int (e^{iyf_n} - 1) d\mu\big)$$

(by (a))

$$= \exp\big(\gamma \lim_{n\to\infty} \int (e^{iyf_n} - 1) d\mu\big) = \exp\big(\gamma \int (e^{iyf} - 1) d\mu\big),$$

as claimed.

Remark Recall that a Poisson random variable with expectation γ has characteristic function $y \mapsto \exp(\gamma(e^{iy} - 1))$ (part (a) of the proof of 285Q), corresponding to the case $f = \chi F$ where $\mu F = 1$. The random variables Q_f have **compound Poisson** distributions.

495N If our underlying measure is a Radon measure, we can look for Radon measures on $\mathcal{P}X$ to represent the Poisson point processes on X. There seem to be difficulties in general, but I can offer the following. See also 495Yc.

Proposition Let $(X, \mathfrak{T}, \Sigma, \mu)$ be a σ-compact locally compact Radon measure space, and $\gamma > 0$. Give the space $\mathcal{C}$ of closed subsets of X its k-Vietoris topology (476Cd).

(i) There is a unique Radon measure $\tilde{\nu}$ on $\mathcal{C}$ such that

$$\tilde{\nu}\{C : \#(C \cap E_i) \neq \emptyset \text{ for every } i \leq r\} = \prod_{i=0}^{r} 1 - e^{-\gamma\mu E_i}$$

whenever $E_0, \ldots, E_r \subseteq X$ are disjoint sets of finite measure.

(ii) If $E_0, \ldots, E_r$ are disjoint sets of finite measure, none including any singleton set of non-zero measure, and $n_i \in \mathbb{N}$ for $i \leq r$, then

$$\tilde{\nu}\{C : \#(C \cap E_i) = n_i \text{ for every } i \leq r\} = \prod_{i=0}^{r} \frac{(\gamma\mu E_i)^{n_i}}{n_i!} e^{-\gamma\mu E_i}.$$

(iii) If μ is atomless and ν is the Poisson point process on X with density γ, then $\mathcal{C}$ is ν-conegligible and $\tilde{\nu}$ extends the subspace measure $\nu|\mathcal{C}$.

proof (a) Recall that $\mathcal{C}$ is Hausdorff (476Cd). Because X is locally compact and σ-compact, there is a sequence $\langle H_n\rangle_{n\in\mathbb{N}}$ of relatively compact open sets covering X. For each n set $H'_n = H_n \setminus \bigcup_{i<n} H_i$; then $\langle H'_n\rangle_{n\in\mathbb{N}}$ is a disjoint sequence of Borel sets of finite measure covering X. Set $\mathcal{H} = \{H'_n : n \in \mathbb{N}, \mu H'_n > 0\}$. Then $\mathcal{H}$ is a countable maximal almost-disjoint family of measurable sets of non-zero finite measure. Build Ω, λ and $\phi : \Omega \to \mathcal{P}X$ from $\mathcal{H}$ as in the proof of 495B. This time, however, observe that all the μ'_H are Radon measures (416Rb), while surely the Poisson distributions ν_H on $\mathbb{N}$ also are, so that we have a Radon measure $\tilde{\lambda}$ on Ω extending λ (417Q).

(b) $\phi(\omega) \in \mathcal{C}$ for every $\omega \in \Omega$. **P** For each $H \in \mathcal{H}$, $H \cap \phi(\omega) = \{x_{Hn}(\omega) : n < m_H(\omega)\}$ is finite. Since each H_n meets only finitely many members of $\mathcal{H}$, $\phi(\omega) \cap H_n$ is finite for each n; because $\{H_n : n \in \mathbb{N}\}$ is an open cover of the Hausdorff space X, this is enough to ensure that $\phi(\omega)$ is closed. **Q**

(c) $\phi : \Omega \to \mathcal{C}$ is continuous. **P** (i) If $G \subseteq X$ is open, then

$$\{\omega : G \cap \phi(\omega) \neq \emptyset\} = \bigcup_{H\in\mathcal{H}, n\in\mathbb{N}} \{\omega : m_H(\omega) > n, x_{Hn}(\omega) \in G\}$$

is open. (ii) If $K \subseteq X$ is compact, there is some $r \in \mathbb{N}$ such that $K \subseteq \bigcup_{i\leq r} H_i$, so that $\mathcal{H}_0 = \{H : H \in \mathcal{H}, H \cap K \neq \emptyset\}$ is finite. Now

$$\{\omega : \phi(\omega) \cap K = \emptyset\} = \bigcap_{H\in\mathcal{H}_0} \bigcup_{n\in\mathbb{N}} \bigcap_{i<n} \{\omega : m_H(\omega) = n, x_{Hi}(\omega) \notin K\}$$

is open. (iii) By 4A2B(a-ii), ϕ is continuous. **Q**

(d) Accordingly we have a Radon measure $\tilde{\nu}$ on $\mathcal{C}$ defined by setting $\tilde{\nu}(\mathcal{S}) = \tilde{\lambda}\phi^{-1}[\mathcal{S}]$ whenever $\mathcal{S} \subseteq \mathcal{C}$ and $\phi^{-1}[\mathcal{S}]$ is measured by $\tilde{\lambda}$ (418I).

If $E_0, \ldots, E_r \in \Sigma$ are disjoint sets of finite measure, then, defining g_{E_i} as in 495B,

$$\begin{aligned}\tilde{\nu}\{C : C \cap E_i \neq \emptyset \text{ for every } i \leq r\} &= \tilde{\lambda}\{\omega : g_{E_i}(\omega) \geq 1 \text{ for every } i \leq r\} \\ &= \prod_{i=0}^{r} 1 - e^{-\gamma\mu E_i}\end{aligned}$$

as required by (i).

(e) To see that $\tilde{\nu}$ is uniquely defined, let $\tilde{\nu}'$ be another Radon probability measure on $\mathcal{C}$ with the same property. Suppose that we have a compact set $K \subseteq X$ and open sets $G_i \subseteq X$, for $i < r$, and set

$$V = \{C : C \in \mathcal{C}, C \cap K = \emptyset, C \cap G_i \neq \emptyset \text{ for every } i < r\}.$$

Then $\tilde{\nu}V = \tilde{\nu}'V$. **P** For each $n \in \mathbb{N}$, set $G_{ni} = G_i \cap \bigcup_{j\leq n} H_j$ for each i, and set

$$V_n = \{C : C \in \mathcal{C}, C \cap K = \emptyset, C \cap G_{ni} \neq \emptyset \text{ for every } i < r\}.$$

Let $\mathcal{E}_n$ be the finite subalgebra of $\mathcal{P}X$ generated by $\{G_{ni} : i < r\} \cup \{K\}$, $\mathcal{A}_n$ the set of atoms of $\mathcal{E}_n$ and $\mathcal{A}_n^f$ the set of members of $\mathcal{A}_n$ of finite measure. For $\mathcal{I} \subseteq \mathcal{A}_n^f$ set

$$V_{n\mathcal{I}} = \{C : C \in \mathcal{C}, \mathcal{I} = \{A : A \in \mathcal{A}_n^f, C \cap A \neq \emptyset\}\}.$$

Then $V_n = \bigcup_{\mathcal{I} \in \mathfrak{I}_n} V_{n\mathcal{I}}$, where

$$\mathfrak{I}_n = \{\mathcal{I} : \mathcal{I} \subseteq \mathcal{A}_n^f, A \cap K = \emptyset \text{ for every } A \in \mathcal{I}, \text{ for every } i < r \text{ there is an } A \in \mathcal{I} \text{ such that } A \subseteq G_{ni}\}.$$

Now the defining formula for $\tilde{\nu}$ shows that $\tilde{\nu}V_{n\mathcal{I}} = \tilde{\nu}'V_{n\mathcal{I}}$ for every $\mathcal{I} \subseteq \mathcal{A}_n^f$, so that $\tilde{\nu}V_n = \tilde{\nu}'V_n$; and now

$$\tilde{\nu}V = \lim_{n\to\infty} \tilde{\nu}V_n = \lim_{n\to\infty} \tilde{\nu}'V_n = \tilde{\nu}'V. \; \mathbf{Q}$$

Since sets V of the type described form a base for the k-Vietoris topology closed under finite intersections, $\tilde{\nu} = \tilde{\nu}'$ (415H(v)).

(f) If $E \in \Sigma$ has finite measure and does not include any non-negligible singleton, then $\#(E \cap \phi(\omega)) = g_E(\omega)$ for almost every $\omega \in \Omega$. **P** As in part (c) of the proof of 495D, $\#(E \cap \phi(\omega)) = g_E(\omega)$ for every $\omega \in \Omega \setminus A_E$, where

$$A_E = \{\omega : \text{ there are distinct } H, H' \in \mathcal{H} \text{ and } j \in \mathbb{N} \text{ such that } x_{Hj}(\omega) \in H'\} \cup \{\omega : \text{ there are } H \in \mathcal{H} \text{ and distinct } i, j \in \mathbb{N} \text{ such that } x_{Hi}(\omega) = x_{Hj}(\omega) \in E\},$$

and A_E is negligible, because the subspace measure on E is atomless (414G/416Xa). **Q** So if $E_0, \ldots, E_r$ are disjoint sets of finite measure, none including any non-negligible singleton, and $n_i \in \mathbb{N}$ for $i \leq r$,

$$\begin{aligned}\tilde{\nu}\{C : \#(C \cap E_i) = n_i \text{ for every } i \leq r\} &= \tilde{\lambda}\{\omega : g_{E_i}(\omega) = n_i \text{ for every } i \leq r\} \\ &= \prod_{i=0}^{r} \frac{(\gamma\mu E_i)^{n_i}}{n_i!} e^{-\gamma\mu E_i},\end{aligned}$$

as required by (ii).

(g) Now suppose that μ is atomless. Let ν be the Poisson point process on X with density γ. For each n, the set $\{S : S \cap H_n \text{ is finite}\}$ is ν-conegligible, so $\{S : S \cap H_n \text{ is finite for every } n\}$ is ν-conegligible; but as $\langle H_n \rangle_{n\in\mathbb{N}}$ is an open cover of X, this is included in $\mathcal{C}$. So $\mathcal{C}$ is ν-conegligible.

Let T be the σ-algebra of subsets of $\mathcal{P}X$ generated by sets of the form $\{S : \#(S \cap E) = n\}$ where $\mu E < \infty$ and $n \in \mathbb{N}$. Then (ii) here and 495C tell us that $\tilde{\nu}(\mathcal{C} \cap \mathcal{S}) = \nu\mathcal{S}$ whenever $\mathcal{S}$ belongs to T and therefore whenever ν measures $\mathcal{S}$; so that $\tilde{\nu}$ extends the subspace measure $\nu_{\mathcal{C}}$.

495O Proposition Let $(X, \mathfrak{T})$ be a σ-compact locally compact Hausdorff space and $M_{\mathrm{R}}^+(X)$ the set of Radon measures on X. Give $M_{\mathrm{R}}^+(X)$ the topology generated by sets of the form $\{\mu : \mu G > \alpha\}$ and $\{\mu : \mu K < \alpha\}$ where $G \subseteq X$ is open, $K \subseteq X$ is compact and $\alpha \in \mathbb{R}$. Let $\mathcal{C}$ be the space of closed subsets of X with the k-Vietoris topology, and $P_{\mathrm{R}}(\mathcal{C})$ the set of Radon probability measures on $\mathcal{C}$ with its narrow topology (definition: 437Jd). Fix $\gamma > 0$, and for $\mu \in M_{\mathrm{R}}^+(X)$ let $\tilde{\nu}_\mu$ be the Radon measure on $\mathcal{C}$ defined in 495N. Then the function $\mu \mapsto \tilde{\nu}_\mu : M_{\mathrm{R}}^+(X) \to P_{\mathrm{R}}(\mathcal{C})$ is continuous.

proof (a) Recall that because X is locally compact and Hausdorff, $\mathcal{C}$ is compact and Hausdorff (476Cd). Fix an open set $W_0 \subseteq \mathcal{C}$, $\alpha_0 > 0$ and $\mu_0 \in M_{\mathrm{R}}^+(X)$ such that $\tilde{\nu}_{\mu_0} W_0 > \alpha_0$. Let $\mathcal{E}$ be the family of relatively compact Borel subsets E of X such that $\mu_0(\partial E) = 0$. Then $\mathcal{E}$ is a subring of $\mathcal{P}X$ (4A2Bi). Also $\mu \mapsto \mu E : M_{\mathrm{R}}^+(X) \to [0, \infty[$ is continuous at μ_0 for every $E \in \mathcal{E}$. **P** If $E \in \mathcal{E}$ and $\epsilon > 0$, then

$$\begin{aligned}&\{\mu : \mu_0 E - \eta < \mu E < \mu_0 E + \eta\} \\ &\quad \supseteq \{\mu : \mu(\operatorname{int} E) > \mu_0(\operatorname{int} E) - \eta, \, \mu(X \setminus \overline{E}) > \mu_0(X \setminus \overline{E}) - \eta\}\end{aligned}$$

is a neighbourhood of μ_0. **Q**

(b) Next, $\mathcal{U} = \mathcal{E} \cap \mathfrak{T}$ is a base for $\mathfrak{T}$ (411Gi). It follows that the family $\mathcal{V}$ of sets of the form

$$\{C : C \in \mathcal{C}, C \cap U_i \neq \emptyset \text{ for } i \leq r, C \cap \overline{U} = \emptyset\},$$

where $U, U_0, \ldots, U_r \in \mathcal{U}$, is a base for the k-Vietoris topology on $\mathcal{C}$. **P** If $W \subseteq \mathcal{C}$ is open for the k-Vietoris topology and $C_0 \in W$, there are $r \in \mathbb{N}$, open sets $G_i \subseteq X$ for $i \leq r$ and a compact set $K \subseteq X$ such that

$$C_0 \in \{C : C \cap G_i \neq \emptyset \text{ for each } i \leq r,\ C \cap K = \emptyset\} \subseteq W.$$

For each $i \leq r$ choose $x_i \in C_0 \cap G_i$ and $U_i \in \mathcal{U}$ such that $x_i \in U_i \subseteq G_i$. Because X is locally compact and Hausdorff, it is regular, so every point of K belongs to a member of $\mathcal{U}$ with closure disjoint from C_0; because $\mathcal{U}$ is closed under finite unions, there is a $U \in \mathcal{U}$ such that $K \subseteq U$ and $C_0 \cap \overline{U} = \emptyset$. Now

$$\{C : C \in \mathcal{C},\ C \cap U_i \neq \emptyset \text{ for } i \leq r,\ C \cap \overline{U} = \emptyset\}$$

belongs to $\mathcal{V}$, contains C_0 and is included in W. As C_0 and W are arbitrary, $\mathcal{V}$ is a base for the k-Vietoris topology on $\mathcal{C}$. **Q**

(c) If $V \in \mathcal{V}$, then $\mu \mapsto \tilde{\nu}_\mu V : M^+_{\mathrm{R}}(X) \to [0,1]$ is continuous at μ_0. **P** Express V as $\{C : C \in \mathcal{C}, C \cap U_i \neq \emptyset \text{ for } i \leq r,\ C \cap \overline{U} = \emptyset\}$, where U_i, $U \in \mathcal{U}$. Let $\mathcal{A}$ be the set of atoms of the finite subring of $\mathcal{E}$ generated by $\{U_i : i \leq r\} \cup \{\overline{U}\}$. For $\mathcal{I} \subseteq \mathcal{A}$ set

$$V_{\mathcal{I}} = \{C : C \in \mathcal{C},\ \mathcal{I} = \{A : A \in \mathcal{A},\ C \cap A \neq \emptyset\}.$$

Let $\mathfrak{I}$ be the set of those $\mathcal{I} \subseteq \mathcal{A}$ such that $A \cap \overline{U} = \emptyset$ for every $A \in \mathcal{I}$ and for every $i \leq r$ there is an $A \in \mathcal{I}$ such that $A \subseteq U_i$. Then $\langle V_{\mathcal{I}} \rangle_{\mathcal{I} \in \mathfrak{I}}$ is a partition of V. Moreover, for any $\mu \in M^+_{\mathrm{R}}(X)$ and $\mathcal{I} \subseteq \mathcal{A}$,

$$\tilde{\nu}_\mu V_{\mathcal{I}} = \prod_{A \in \mathcal{I}} e^{-\gamma\mu A} \prod_{A \in \mathcal{A} \setminus \mathcal{I}} (1 - e^{-\gamma \mu A}).$$

Since each $\mu \mapsto \mu A$ is continuous at μ_0, by (a), so are the functionals $\mu \mapsto \tilde{\nu}_\mu V_{\mathcal{I}}$, for $\mathcal{I} \subseteq \mathcal{A}$, and $\mu \mapsto \tilde{\nu}_\mu V = \sum_{\mathcal{I} \in \mathfrak{I}} \tilde{\nu}_\mu V_{\mathcal{I}}$. **Q**

(d) Let $\mathcal{V}^*$ be the family of Borel subsets V of $\mathcal{C}$ such that $\mu \mapsto \tilde{\nu}_\mu V : M^+_{\mathrm{R}}(X) \to [0, \infty[$ is continuous at μ_0. Then $\mathcal{V} \subseteq \mathcal{V}^*$ (by (c)), $\mathcal{C} \in \mathcal{V}^*$ and $V \setminus V' \in \mathcal{V}^*$ whenever V, $V' \in \mathcal{V}^*$ and $V' \subseteq V$. Because $\mathcal{V}$ is closed under finite intersections, it follows that $\mathcal{V}^*$ includes the algebra of subsets of $\mathcal{C}$ generated by $\mathcal{V}$ (313Ga); in particular, any finite union of members of $\mathcal{V}$ belongs to $\mathcal{V}^*$.

(e) Let us return to the open set $W_0 \subseteq \mathcal{C}$ and the $\alpha_0 \in \mathbb{R}$ of part (a). Because $\tilde{\nu}_{\mu_0}$ is τ-additive and $\mathcal{V}$ is a base for the topology of $\mathcal{C}$ ((b) above), there is a finite family $\mathcal{V}_0 \subseteq \mathcal{V}$ such that $V_0 = \bigcup \mathcal{V}_0$ is included in W_0 and $\tilde{\nu}_{\mu_0} V_0 > \alpha_0$. But this means that

$$\{\mu : \mu \in M^+_{\mathrm{R}}(X),\ \tilde{\nu}_\mu W_0 > \alpha_0\} \supseteq \{\mu : \mu \in M^+_{\mathrm{R}}(X),\ \tilde{\nu}_\mu V_0 > \alpha_0\}$$

is a neighbourhood of μ_0. As μ_0 is arbitrary, $\{\mu : \tilde{\nu}_\mu W_0 > \alpha_0\}$ is open; as W_0 and α_0 are arbitrary, $\mu \mapsto \tilde{\nu}_\mu$ is continuous.

495P There are many constructions which, in particular cases, can be used as an alternative to the method of 495B-495D in setting up Poisson point processes. I give one which applies to the half-line $[0, \infty[$ with Lebesgue measure.

Theorem Let $\gamma > 0$, and let ν be the Poisson point process on $[0, \infty[$, with Lebesgue measure, with density γ. Let λ_0 be the exponential distribution with expectation $1/\gamma$, regarded as a Radon probability measure on $]0, \infty[$, and λ the corresponding product measure on $]0, \infty[^{\mathbb{N}}$. Define $\phi :]0, \infty[^{\mathbb{N}} \to \mathcal{P}([0, \infty[)$ by setting $\phi(x) = \{\sum_{i=0}^n x(i) : n \in \mathbb{N}\}$ for $x \in]0, \infty[^{\mathbb{N}}$. Then ϕ is a measure space isomorphism between $]0, \infty[^{\mathbb{N}}$ and a ν-conegligible subset of $\mathcal{P}([0, \infty[)$.

Remark As I seem not to have mentioned exponential distributions earlier in this treatise, I remark now that the **exponential distribution** with parameter γ has distribution function

$$F(t) = 0 \text{ if } t < 0,\ 1 - e^{-\gamma t} \text{ if } t \geq 0,$$

and probability density function

$$f(t) = 0 \text{ if } t \leq 0,\ \gamma e^{-\gamma t} \text{ if } t > 0;$$

its expectation is

$$\int_0^\infty \gamma t e^{-\gamma t} dt = -\int_0^\infty \tfrac{d}{dt} \tfrac{\gamma t + 1}{\gamma} e^{-\gamma t} dt = \frac{1}{\gamma}.$$

Because (when regarded as a Radon probability measure on $\mathbb{R}$, following my ordinary rule set out in §271) it gives measure zero to $]-\infty, 0]$, it can be identified with the subspace measure on $]0, \infty[$, as here.

proof (a) For each $n \in \mathbb{N}$, $\#(S \cap [0,n])$ is finite for ν-almost every S; so the set

$$Q_0 = \{S : S \subseteq [0,\infty[,\ \#(S \cap [0,n]) \text{ is finite for every } n\}$$

is ν-conegligible. Next, the sets $\{S : S \cap [n, n+1[\neq \emptyset\}$ are ν-independent and have measure $1 - e^{-\gamma} > 0$, so

$$\{S : S \cap [n, n+1[\neq \emptyset \text{ for infinitely many } n\}$$

is ν-conegligible (273K). Finally, $\nu\{S : 0 \in S\} = 0$, so $Q = \{S : S \in Q_0,\ 0 \notin S,\ S \text{ is infinite}\}$ is ν-conegligible. For $S \in Q$, let $\langle g_n(S)\rangle_{n\in\mathbb{N}}$ be the increasing enumeration of S. Let T be the σ-algebra of subsets of $\mathcal{P}([0,\infty[)$ generated by sets of the form $\{S : \#(S \cap E) = n\}$ where $E \subseteq [0,\infty[$ has finite measure and $n \in \mathbb{N}$. Then, for $n \in \mathbb{N}$ and $\alpha \geq 0$, $\{S : g_n(S) \leq \alpha\} = \{S : \#(S \cap [0,\alpha]) \geq n+1\}$ belongs to T, so g_n is T-measurable. Set $h_0(S) = g_0(S)$, $h_n(S) = g_n(S) - g_{n-1}(S)$ for $n \geq 1$, and $h(S) = \langle h_n(S)\rangle_{n\in\mathbb{N}}$; then $h : Q \to]0,\infty[^{\mathbb{N}}$ is a bijection, and its inverse is ϕ.

(b) For each $k \in \mathbb{N}$, $I_S = \{i : i \in \mathbb{N},\ S \cap \left[2^{-k}i, 2^{-k}(i+1)\right[\neq \emptyset\}$ is infinite for every $S \in Q$. So we can define $g_{kn} : Q \to]0,\infty[$, for each n, by taking $g_{kn}(S) = 2^{-k}(j+1)$ if $j \in I_S$ and $\#(I_S \cap j) = n$. Because all the sets $\{S : j \in I_S\}$ belong to T, each g_{kn} is T-measurable, and $\langle g_{kn}\rangle_{k\in\mathbb{N}}$ is a non-increasing sequence with limit g_n. Set $h_{k0}(S) = g_{k0}(S)$ and $h_{kn}(S) = g_{k,n+1}(S) - g_{kn}(S)$ for $n \geq 1$. Then $h_n = \lim_{k\to\infty} h_{kn}$.

(d) For any $n \in \mathbb{N}$, $j_0, \ldots, j_n \in \mathbb{N}$, $k \in \mathbb{N}$, set $j'_r = \sum_{i=0}^{r} j_i$ for $r \leq n$. Then

$$\begin{aligned}
&\nu\{S : S \in Q, h_{ki}(S) = 2^{-k}(j_i+1) \text{ for every } i \leq n\}\\
&\quad = \nu\{S : S \in Q,\ g_{kr}(S) = 2^{-k}(r+1+j'_r) \text{ for every } r \leq n\}\\
&\quad = \nu\{S : S \cap \left[2^{-k}(r+j'_r), 2^{-k}(r+1+j'_r)\right[\neq \emptyset \text{ for every } r \leq n,\\
&\qquad\qquad S \cap \left[0, 2^{-k}j_0\right[= \emptyset,\\
&\qquad\qquad S \cap \left[2^{-k}(r+1+j'_r), 2^{-k}(r+1+j'_{r+1})\right[= \emptyset \text{ for every } r < n\}\\
&\quad = (1-\exp(-2^{-k}\gamma))^{n+1}\exp(-2^{-k}\gamma j_0)\prod_{r<n}\exp(-2^{-k}\gamma(j'_{r+1}-j'_r))\\
&\quad = \prod_{i=0}^{n}(1-\exp(-2^{-k}\gamma))\exp(-2^{-k}\gamma j_i)
\end{aligned}$$

This means that the h_{ki}, for $i \in \mathbb{N}$ are independent, with

$$\Pr(h_{ki} = 2^{-k}(j+1)) = (1-e^{-2^{-k}\gamma})e^{-2^{-k}\gamma j}$$

for each j. Since $h_{ki} \to h_i$ ν-a.e. for each i, $\langle h_i\rangle_{i\in\mathbb{N}}$ is also independent (367W). Now, for any $\alpha > 0$,

$$\begin{aligned}
\Pr(h_{ki} \leq \alpha) &= \sum_{2^{-k}(j+1)\leq\alpha} (1-\exp(-2^{-k}\gamma))\exp(-2^{-k}\gamma j)\\
&= 1 - \exp(-2^{-k}\gamma\lfloor 2^k\alpha\rfloor) \to 1 - e^{-\gamma\alpha}
\end{aligned}$$

as $k \to \infty$. So

$$\begin{aligned}
\Pr(h_i \leq \alpha) &= \inf_{\beta>\alpha} \liminf_{i\to\infty} \Pr(h_{ki} \leq \beta)\\
&= \inf_{\beta>\alpha} 1 - e^{-\gamma\beta} = 1 - e^{-\gamma\alpha}
\end{aligned} \tag{271L}$$

for every $\alpha \geq 0$ and every $i \in \mathbb{N}$.

(e) Accordingly $\langle h_i\rangle_{i\in\mathbb{N}}$ is an independent sequence of random variables, each exponentially distributed with expectation $1/\gamma$. It follows that $h : Q \to]0,\infty[^{\mathbb{N}}$ is inverse-measure-preserving for the subspace measure ν_Q and λ (254G).

Observe next that if $E \subseteq [0,\infty[$ is Lebesgue measurable and $n \in \mathbb{N}$, then

$$\{x : x \in]0,\infty[^{\mathbb{N}}, \#(\phi(x) \cap E) = n\} = \bigcup_{I \in [\mathbb{N}]^n} \{x : \textstyle\sum_{i=0}^{j} x(i) \in E \iff j \in I\} \in \Lambda,$$

writing Λ for the domain of λ. So ϕ is (Λ, T)-measurable. Now, for any $W \in \mathrm{T}$,

$$\lambda\phi^{-1}[W] = \nu(h^{-1}[\phi^{-1}[W]]) = \nu(W \cap Q) = \nu W.$$

So ϕ is inverse-measure-preserving for λ and for $\nu\restriction\mathrm{T}$. Since λ is complete and ν is defined as the completion of its restriction to T, ϕ is inverse-measure-preserving for λ and ν. Thus ϕ and h are the two halves of an isomorphism between $(]0,\infty[^{\mathbb{N}}, \lambda)$ and the subspace (Q, ν_Q), as claimed.

495X Basic exercises (a) Let (X, Σ, μ) be an atomless measure space, and ν a Poisson point process on X. (i) Show that $[X]^{\leq\omega}$ has full outer measure for ν. (ii) Show that if μ is semi-finite then $[X]^{\leq\omega}$ is conegligible iff μ is σ-finite. (iii) Show that if μ is semi-finite, then $[X]^{<\omega}$ is non-negligible iff $[X]^{<\omega}$ is conegligible iff μ is totally finite.

(b) Let (X, Σ, μ) be an atomless measure space and $\mathcal{E}$ a countable partition of X into measurable sets; fix $\gamma > 0$. Let ν be the Poisson point process on X with density γ, and for each $E \in \mathcal{E}$ let ν_E be the Poisson point process on E with density γ corresponding to the subspace measure μ_E on E. Let λ be the product of the family $\langle \nu_E \rangle_{E\in\mathcal{E}}$. Show that the map $S \mapsto \langle S \cap E\rangle_{E\in\mathcal{E}} : \mathcal{P}X \to \prod_{E\in\mathcal{E}} \mathcal{P}E$ is a measure space isomorphism for ν and λ.

>(c) Let (X, Σ, μ) be an atomless measure space and $\mathfrak{T}$ a topology on X such that X is covered by a sequence of open sets of finite outer measure. Let ν be a Poisson point process on X. Show that ν-almost every set $S \subseteq X$ is locally finite in the sense that X is covered by the open sets meeting S in finite sets; in particular, if X is Hausdorff, then ν-almost every subset of X is closed.

>(d) Let (X, Σ, μ) be an atomless measure space, and for $\gamma > 0$ let ν_γ be the Poisson point process on X with density γ. Show that for any γ, $\delta > 0$ the map $(S, T) \mapsto S \cup T : \mathcal{P}X \times \mathcal{P}X \to \mathcal{P}X$ is inverse-measure-preserving for the product measure $\nu_\gamma \times \nu_\delta$ and $\nu_{\gamma+\delta}$.

(e) Let (X, Σ, μ) be an atomless semi-finite measure space, and ν the Poisson point process on X with density 1. Show that ν is perfect iff μ is.

(f) Let $(\mathfrak{A}, \bar\mu)$ be a measure algebra. Show that there is a probability measure λ on $\mathbb{R}^{\mathfrak{A}^f}$ such that (i) for every $a \in \mathfrak{A}^f$ the corresponding marginal measure on $\mathbb{R}$ is the Poisson distribution with expectation $\bar\mu a$ (ii) whenever $a_0, \dots, a_n \in \mathfrak{A}^f$ are disjoint, the functions $z \mapsto z(a_i) : \mathbb{R}^{\mathfrak{A}^f} \to \mathbb{R}$ are stochastically independent with respect to λ. (*Hint*: prove the result for finite $\mathfrak{A}$ and use 454D.) Use this to prove 495J.

(g) Let U be a Hilbert space. Show that there are a probability algebra $(\mathfrak{B}, \bar\lambda)$ and a linear operator $T : U \to L^0(\mathfrak{B})$ such that (i) for every $u \in U$, Tu has a normal distribution with expectation 0 and variance $\|u\|_2^2$ (ii) if $\langle u_i\rangle_{i\in I}$ is an orthogonal family in U then $\langle Tu_i\rangle_{i\in I}$ is $\bar\lambda$-independent. (*Hint*: see the proof of 456G.)

(h) Let U be an L-space. Show that there are a probability algebra $(\mathfrak{B}, \bar\lambda)$ and a linear operator $T : U \to L^1(\mathfrak{B}, \bar\lambda)$ such that (i) for every $u \in U$, Tu has a standard gamma distribution (definition: 455Xe) with expectation $\|u\|$ (ii) if $\langle u_i\rangle_{i\in I}$ is a disjoint family in U then $\langle Tu_i\rangle_{i\in I}$ is $\bar\lambda$-independent.

(i) Let ν be the Poisson point process with density 1 on $[0,\infty[$ with Lebesgue measure. Set $Q_0 = \{S : S \subseteq [0,\infty[, S\cap[0,n]$ is finite for every $n\}$ and for $S \in Q_0$ set $\psi(S)(t) = \#(S\cap[0,t])$ for $t \in [0,\infty[$. Show that ψ is inverse-measure-preserving for the subspace measure ν_{Q_0} and the Baire measure on $\mathbb{R}^{[0,\infty[}$ described in 455Xc.

(j) Let (Y, T, ν) be a probability space, and λ_0 the exponential distribution with expectation 1, regarded as a Radon measure on $]0,\infty[$. Let λ be the product measure $\lambda_0^{\mathbb{N}} \times \nu^{\mathbb{N}}$ on $]0,\infty[^{\mathbb{N}} \times Y^{\mathbb{N}}$. Set $\phi(x, y) = \{(\sum_{i=0}^{n} x(i), y(n)) : n \in \mathbb{N}\}$ for $x \in]0,\infty[^{\mathbb{N}}$ and $y \in Y^{\mathbb{N}}$. Show that $\phi :]0,\infty[^{\mathbb{N}} \times Y^{\mathbb{N}} \to \mathcal{P}(]0,\infty[\times Y)$ is a measure space isomorphism between $(]0,\infty[^{\mathbb{N}} \times Y^{\mathbb{N}}, \lambda)$ and a conegligible set for the Poisson point process on $]0,\infty[\times Y$ with density 1 for the c.l.d. product measure $\mu_L \times \nu$, where μ_L is Lebesgue measure.

(k) Let $\mathcal{C}$ be the family of closed subsets of $[0,\infty[$. Let ρ be the usual metric on $[0,\infty[$ and $\tilde{\rho}$ the corresponding Hausdorff metric on $\mathcal{C}\setminus\{\emptyset\}$. Let ν the Poisson point process on $[0,\infty[$ with density 1 over Lebesgue measure. Show that any $\tilde{\rho}$-compact subset of $\mathcal{C}\setminus\{\emptyset\}$ is ν-negligible.

(l) Show that the topology on $M_{\mathrm{R}}^{+}(X)$ described in 495O is just the topology induced by the natural embedding of $M_{\mathrm{R}}(X)$ into $C_k(X)^{\sim}$ (436J) and the weak topology $\mathfrak{T}_s(C_k(X)^{\sim},C_k(X))$, where $C_k(X)$ is the Riesz space of continuous real-valued functions on X with compact support.

(m) Let X be a σ-compact locally compact Hausdorff space, $\mathcal{C}$ the family of closed subsets of X with its k-Vietoris topology, and $P_{\mathrm{R}}(\mathcal{C})$ the set of Radon probability measures on $\mathcal{C}$ with its narrow topology. Let μ be a Radon measure on X and $\gamma>0$, and $\tilde{\nu}$ the Radon measure on $\mathcal{C}$ defined from μ and γ as in 495N. Let Q be the set of families $q=\langle(x_{qi},E_{qi})\rangle_{i\in I_q}$ such that I_q is a countable set, $\langle E_{qi}\rangle_{i\in I_q}$ is a disjoint family of measurable sets of finite measure, and $\langle x_{qi}\rangle_{i\in I_q}$ is a family of distinct points in X; for $q\in Q$ set $A_q=\{x_{qi}:i\in I_q\}$. (i) Show that for each $q\in Q$ we have a Radon measure $\tilde{\nu}_q$ on $\mathcal{C}$ defined by saying that $\tilde{\nu}_q(\mathcal{P}A_q)=1$ and

$$\tilde{\nu}_q\{C:x_{qi}\notin C\text{ for }i\in J\}=\exp(-\gamma\textstyle\sum_{i\in J}\mu E_{qi})$$

for every $J\subseteq I_q$. (ii) Show that for every neighbourhood V of $\tilde{\nu}$ for the narrow topology on $P_{\mathrm{R}}(\mathcal{C})$ there are an open cover $\mathcal{H}$ of X, a compact set $K\subseteq X$ and an $\epsilon>0$ such that $\tilde{\nu}_q\in V$ whenever $q\in Q$, $\mu(K\setminus\bigcup_{i\in I_q}E_{qi})\leq\epsilon$ and for every $i\in I_q$ there is an $H\in\mathcal{H}$ including $E_{qi}\cup\{x_{qi}\}$.

(n) Let $\mathcal{C}$ be the set of closed subsets of $[0,\infty[$ with its k-Vietoris topology. For $\delta\in]0,1]$ let λ_δ be the measure on $\{0,1\}^{\mathbb{N}}$ which is the product of copies of the measure on $\{0,1\}$ in which $\{1\}$ is given measure δ. Define $\phi_\delta:\{0,1\}^{\mathbb{N}}\to\mathcal{C}$ by setting $\phi_\delta(x)=\{n\delta:n\in\mathbb{N},x(n)=1\}$, and let $\tilde{\nu}_\delta$ be the Radon measure $\lambda_\delta\phi_\delta^{-1}$ on $\mathcal{C}$. Show that the Radon measure on $\mathcal{C}$ representing the Poisson point process on $[0,\infty[$ with density 1 over Lebesgue measure is the limit $\lim_{\delta\downarrow0}\tilde{\nu}_\delta$ for the narrow topology on the space of Radon probability measures on $\mathcal{C}$.

(o) Show that the standard gamma distribution with expectation 1 is the exponential distribution with expectation 1.

(p) Let $r\geq1$ be an integer; let μ be Lebesgue measure on $\mathbb{R}^r$ and β_r the volume of the unit ball in $\mathbb{R}^r$. Set $\psi(t)=(t/\beta_r)^{1/r}$ for $t\geq0$, so that the volume of a ball of radius $\psi(t)$ is t. Let S_{r-1} be the unit sphere in $\mathbb{R}^r$ and θ the invariant Radon probability measure on S_{r-1}, so that θ is a multiple of $r-1$-dimensional Hausdorff measure (476M). Let λ_0 be the exponential distribution with expectation 1, regarded as a Radon probability measure on $]0,\infty[$, and λ the product measure $\lambda_0^{\mathbb{N}}\times\theta^{\mathbb{N}}$ on $]0,\infty[^{\mathbb{N}}\times S_{r-1}^{\mathbb{N}}$. Set

$$\phi(x,z)=\{\psi(\textstyle\sum_{i=0}^{n}x(i))z(n):n\in\mathbb{N}\}$$

for $x\in]0,\infty[^{\mathbb{N}}$ and $z\in S_{r-1}^{\mathbb{N}}$. Show that $\phi:]0,\infty[^{\mathbb{N}}\times S_{r-1}^{\mathbb{N}}\to\mathcal{P}(\mathbb{R}^r)$ is a measure space isomorphism between $]0,\infty[^{\mathbb{N}}\times S_{r-1}^{\mathbb{N}}$ and a conegligible set for the Poisson point process on $\mathbb{R}^r$ with density 1.

495Y Further exercises (a) Let U be an L-space. Show that there are a probability algebra $(\mathfrak{B},\bar{\lambda})$ and a linear operator $T:U\to L^0(\mathfrak{B})$ such that (i) for every $u\in L^1(\mathfrak{A},\bar{\mu})$, Tu has a Cauchy distribution with centre 0 and scale parameter $\|u\|$ (ii) if $\langle u_i\rangle_{i\in I}$ is a disjoint family in U then $\langle Tu_i\rangle_{i\in I}$ is $\bar{\lambda}$-independent.

(b) Let $(\mathfrak{A},\bar{\mu})$ be a measure algebra. For $\alpha,\ y\in\mathbb{R}$ set $h_y(\alpha)=e^{iy\alpha}$, and let $\bar{h}_y:L^0(\mathfrak{A})\to L^0_{\mathbb{C}}(\mathfrak{B})$ (definition: 364Yn) be the corresponding operator (to be defined, following the ideas of 364I or otherwise). Show that there are a probability algebra $(\mathfrak{B},\bar{\lambda})$ and a positive linear operator $T:L^1(\mathfrak{A},\bar{\mu})\to L^1(\mathfrak{B},\bar{\lambda})$ such that (i) $\|Tu\|_1=\|u\|_1$ whenever $u\in L^1(\mathfrak{A},\bar{\mu})^+$ (ii) $\langle Tu_i\rangle_{i\in I}$ is $\bar{\lambda}$-independent in $L^0(\mathfrak{B})$ whenever $\langle u_i\rangle_{i\in I}$ is a disjoint family in $L^1(\mathfrak{A},\bar{\mu})$ (iii) $\int\bar{h}_y(Tu)d\bar{\lambda}=\exp(\int(\bar{h}_y(u)-\chi1)d\bar{\mu})$ for every $u\in L^1(\mathfrak{A},\bar{\mu})$ and $y\in\mathbb{R}$.

(c) Let (X,ρ) be a totally bounded metric space, μ a non-totally-finite Radon measure on X, and $\gamma>0$. Let $\mathcal{C}$ be the set of closed subsets of X, and $\tilde{\rho}$ the Hausdorff metric on $\mathcal{C}\setminus\{\emptyset\}$. (i) Show that there is a unique Radon measure $\tilde{\nu}$ on $\mathcal{C}\setminus\{\emptyset\}$ such that

$$\tilde{\nu}\{C:\#(C\cap E_i)\neq\emptyset\text{ for every }i\leq r\}=\textstyle\prod_{i=0}^{r}1-e^{-\gamma\mu E_i}$$

whenever $E_0, \dots, E_r \subseteq X$ are disjoint sets of finite measure. (ii) Show that if $E_0, \dots, E_r$ are disjoint sets of finite measure, none including any singleton set of non-zero measure, and $n_i \in \mathbb{N}$ for $i \leq r$, then

$$\tilde{\nu}\{C : \#(C \cap E_i) = n_i \text{ for every } i \leq r\} = \prod_{i=0}^{r} \frac{(\gamma\mu E_i)^{n_i}}{n_i!} e^{-\gamma\mu E_i}.$$

(iii) Show that if μ is atomless and ν is the Poisson point process on X with density γ, then $\mathcal{C} \setminus \{\emptyset\}$ is ν-conegligible and $\tilde{\nu}$ extends the subspace measure $\nu{\restriction}\mathcal{C} \setminus \{\emptyset\}$.

495 Notes and comments The underlying fact on which this section relies is that the Poisson distributions form a one-parameter semigroup of infinitely divisible distributions, with $\nu_\alpha * \nu_\beta = \nu_{\alpha+\beta}$ for all $\alpha, \beta > 0$. Other well-known families with this property are normal distributions, Cauchy distributions and gamma distributions; for each of these we have results corresponding to 495B and 495K (495Xg, 495Ya, 495Xh). The same distributions appeared, for the same reason, in the evolving processes of 455C and 455Xc-455Xe. Observe that the version for the normal distribution is related to the Gaussian processes of §456. The 'compound Poisson' distributions of 495M provide further examples, which approach the general form of infinitely divisible distributions (Loève 77, §23, or Fristedt & Gray 97, §16.3).

The special feature of the Poisson point process, in this context, is the fact that (for atomless measure spaces (X, μ)) it can be represented by a measure on $\mathcal{P}X$ rather than on some abstract auxiliary space (495D); so that we have a notion of 'random subset', and can discuss the expected topological properties of subsets of X (495Xa, 495Xc). In Euclidean spaces the geometric properties of these random subsets are also of great interest; see Meester & Roy 96. Here I look at the relations between this construction and others which have been prominent in this book, such as inverse-measure-preserving functions (495G) and disintegrations (495H-495I). In the latter we find ourselves in an interesting difficulty. If, as in 495H, we have a measure space $X = \tilde{X} \times [0,1]$, where $\tilde{X}$ is an atomless measure space, then it is natural to suppose that our Poisson process on X can be represented by picking a random subset T of $\tilde{X}$ and then, for each $t \in T$, a random $(t, \alpha) \in X$. The obvious model for this idea is the map $(T, z) \mapsto \{(t, z(t)) : t \in T\} : \mathcal{P}\tilde{X} \times [0,1]^{\tilde{X}} \to \mathcal{P}X$. The problem with this model is that the map is simply not measurable for the standard σ-algebras on $\mathcal{P}\tilde{X}$, $\mathcal{P}\tilde{X} \times [0,1]^{\tilde{X}}$ and $\mathcal{P}X$. When we have a canonical ordering in order type ω of almost every subset of $\tilde{X}$ ('almost every' with respect to the Poisson point process on $\tilde{X}$, of course), as in 495Xp, there can be a way around this, cutting $[0,1]^{\tilde{X}}$ down to a countable product and re-inventing the representation of pairs (T, z) as subsets of X. But in the general case it seems that we have to set up a disintegration of the Poisson point process on X over the Poisson point process on $\tilde{X}$ which does not correspond to any measure on a product $\mathcal{P}\tilde{X} \times \Omega$.

Following my usual custom, I have expressed the theorems of this section in terms of arbitrary (atomless) measure spaces. The results are not quite without interest when applied to totally finite measures, but their natural domain is the class of non-totally-finite σ-finite measures, as in 495N-495P. There is an unavoidable obstacle if we wish to extend the ideas to measure spaces which are not atomless. The functions $S \mapsto \#(S \cap E)$ can no longer have Poisson distributions, since if E is a singleton of positive measure then we shall have a non-trivial two-valued random variable. In 495N-495O I take one of the possible resolutions of this, with measures $\tilde{\nu}$ on spaces of subsets for which at least the functions $S \mapsto \#(S \cap E)$, for disjoint E, are independent (495Xm). An alternative which is sometimes appropriate is to work with functions $h : X \to \mathbb{N}$ and $\sum_{x \in E} h(x)$ in place of subsets S of X and $\#(S \cap E)$; see Fristedt & Gray 97, §29.

In 495J-495L we have a little cluster of results which are relevant to rather different questions, to which I expect to return in Chapter 52 of Volume 5. The objective here is to connect the structure of a measure algebra or Banach lattice of arbitrarily large cellularity with something which can be realized in a probability space. In each case, disjointness is transformed into stochastic independence. Once again, the special feature of the Poisson point process is that we have a concrete representation of a linear operator which can also be described in a more abstract way (495L).

The construction of 495B-495D seems to be the most straightforward way to generate Poisson point processes. It fails however to give a direct interpretation of one of the most important approaches to these processes, as limits of purely atomic processes in which sets are chosen by including or excluding individual points independently (495Xm-495Xn). In order to make sense of the limit here it seems that we need to put some further structure onto the underlying measure space, and 'σ-finite locally compact Radon measure space' is sufficient to give an interesting pair of positive results (495N-495O).

Appendix to Volume 4

Useful facts

As is to be expected, we are coming in this volume to depend on a wide variety of more or less recondite information, and only an exceptionally broad mathematical education will have covered it all. While all the principal ideas are fully expressed in standard textbooks, there are many minor points where I need to develop variations on the familiar formulations. A little under half the material, by word-count, is in general topology (§4A2), where I begin with some pages of definitions. I follow this with a section on Borel and Baire σ-algebras, Baire property algebras and cylindrical algebras (§4A3), worked out a little more thoroughly than the rest of the material. The other sections are on set theory (§4A1), linear analysis (§4A4), topological groups (§4A5) and Banach algebras (§4A6).

4A1 Set theory

For this volume, we need fragments from four topics in set theory and one in Boolean algebra. The most important are the theory of closed cofinal sets and stationary sets (4A1B-4A1C) and infinitary combinatorics (4A1D-4A1H). Rather more specialized, we have the theory of normal (ultra)filters (4A1J-4A1L) and a mention of Ostaszewski's ♣ (4A1M-4A1N), used for an example in §439. I conclude with a simple result on the cardinality of σ-algebras (4A1O).

4A1A Cardinals again (a) An infinite cardinal κ is **regular** if it is not the supremum of fewer than κ smaller cardinals, that is, if $\operatorname{cf}\kappa = \kappa$. Any infinite successor cardinal is regular. (Kunen 80, I.10.37; Jech 78, p. 40; Just & Weese 96, 11.18; Levy 79, IV.3.11.) In particular, $\omega_1 = \omega^+$ is regular.

(b) If ζ is an ordinal, X a set then I say that a family $\langle x_\xi\rangle_{\xi<\zeta}$ in X **runs over** X **with cofinal repetitions** if $\{\xi : \xi < \zeta,\ x_\xi = x\}$ is cofinal with ζ for every $x \in X$. Now if X is any non-empty set and κ is a cardinal greater than or equal to $\max(\omega, \#(X))$, there is a family $\langle x_\xi\rangle_{\xi<\kappa}$ running over X with cofinal repetitions. **P** By 3A1Ca, there is a surjection $\xi \mapsto (x_\xi, \alpha_\xi) : \kappa \to X \times \kappa$. **Q**

(c) The cardinal $\mathfrak{c}$ (i) Every non-trivial interval in $\mathbb{R}$ has cardinal $\mathfrak{c}$. (Enderton 77, p. 131.)

(ii) $\operatorname{cf}(2^\kappa) > \kappa$ for every infinite cardinal κ; in particular, $\operatorname{cf}\mathfrak{c} > \omega$. (Kunen 80, I.10.40; Jech 78, p. 46; Just & Weese 96, 11.24; Levy 79, V.5.2.)

(d) The Continuum Hypothesis This is the statement '$\mathfrak{c} = \omega_1$'; it is neither provable nor disprovable from the ordinary axioms of mathematics, including the Axiom of Choice. As such, it belongs to Volume 5 rather than to the present volume. But I do at one point refer to one of its immediate consequences. If the continuum hypothesis is true, then there is a well-ordering $\preccurlyeq$ of $[0,1]$ such that $([0,1], \preccurlyeq)$ has order type ω_1 (because there is a bijection $f : [0,1] \to \omega_1$, and we can set $s \preccurlyeq t$ if $f(s) \leq f(t)$).

4A1B Closed cofinal sets Let κ be a cardinal.

(a) Note that a subset F of κ is closed in the order topology iff $\sup A \in F$ whenever $A \subseteq F$ is non-empty and $\sup A < \kappa$. (4A2S(a-ii).)

(b) If κ has uncountable cofinality, and $A \subseteq \kappa$ has supremum κ, then $A' = \{\xi : 0 < \xi < \kappa, \xi = \sup(A \cap \xi)\}$ is a closed cofinal set in κ. **P** (i) For any $\eta < \kappa$ we can choose inductively a strictly increasing sequence $\langle \xi_n\rangle_{n\in\mathbb{N}}$ in A starting from $\xi_0 \geq \eta$; now $\xi = \sup_{n\in\mathbb{N}} \xi_n \in A'$ and $\xi \geq \eta$; this shows that A' is cofinal with κ. (ii) If $\emptyset \neq B \subseteq A'$ and $\sup B = \xi < \kappa$, then $A \cap \xi \supseteq A \cap \eta$ for every $\eta \in B$, so

$$\xi = \sup B = \sup_{\eta\in B} \sup(A \cap \eta) = \sup(\textstyle\bigcup_{\eta\in B} A \cap \eta) \leq \sup A \cap \xi \leq \xi$$

and $\xi \in A'$. **Q**

In particular, taking $A = \kappa = \omega_1$, the set of non-zero countable limit ordinals is a closed cofinal set in ω_1.

(c) If $\mathcal{F}$ is a non-empty family of closed cofinal sets in κ and $\#(\mathcal{F}) < \operatorname{cf}\kappa$, then $\bigcap\mathcal{F}$ is a closed cofinal set in κ. (Kunen 80, II.6.8; Just & Weese 97, Theorem 21.3; Levy 79, IV.4.15.) In particular, the intersection of any sequence of closed cofinal sets in ω_1 is again a closed cofinal set in ω_1.

(d) If $\langle F_\xi\rangle_{\xi<\kappa}$ is a family of subsets of κ, the **diagonal intersection** of $\langle F_\xi\rangle_{\xi<\kappa}$ is $\{\xi : \xi < \kappa, \xi \in F_\eta \text{ for every } \eta < \xi\}$. If κ is a regular uncountable cardinal and $\langle F_\xi\rangle_{\xi<\kappa}$ is any family of closed cofinal sets in κ, its diagonal intersection is again a closed cofinal set in κ. (Kunen 80, II.6.14; Jech 78, p. 58; Just & Weese 97, Theorem 21.7; Levy 79, IV.4.20.) In particular, if $f : \kappa \to \kappa$ is any function, then $\{\xi : \xi < \kappa, f(\eta) < \xi \text{ for every } \eta < \xi\}$ is a closed cofinal set in κ, being the diagonal intersection of $\langle \kappa \setminus (f(\xi)+1)\rangle_{\xi<\kappa}$.

4A1C Stationary sets (a) Let κ be a cardinal. A subset of κ is **stationary** in κ if it meets every closed cofinal set in κ; otherwise it is **non-stationary**.

(b) If κ is a cardinal of uncountable cofinality, the intersection of any stationary subset of κ with a closed cofinal set in κ is again a stationary set (because the intersection of two closed cofinal sets is a closed cofinal set); the family of non-stationary subsets of κ is a σ-ideal. (Kunen 80, II.6.9; Just & Weese 97, Lemma 21.11; Levy 79, IV.4.35.)

(c) Pressing-Down Lemma (Fodor's theorem) If κ is a regular uncountable cardinal, $A \subseteq \kappa$ is stationary and $f : A \to \kappa$ is such that $f(\xi) < \xi$ for every $\xi \in A$, then there is a stationary set $B \subseteq A$ such that f is constant on B. (Kunen 80, II.6.15; Jech 78, Theorem 22; Just & Weese 97, Theorem 21.2; Levy 79, IV.4.40.)

(d) There are disjoint stationary sets A, $B \subseteq \omega_1$. (This is easily deduced from 419G or 438Cd, and is also a special case of very much stronger results. See Kunen 80, II.6.12; Jech 78, p. 59; Just & Weese 97, Corollary 23.4; Levy 79, IV.4.48.)

4A1D Δ-systems (a) A family $\langle I_\xi\rangle_{\xi\in A}$ of sets is a **Δ-system** with **root** I if $I_\xi \cap I_\eta = I$ for all distinct ξ, $\eta \in A$.

(b) Δ-system Lemma If $\#(A)$ is a regular uncountable cardinal and $\langle I_\xi\rangle_{\xi\in A}$ is any family of finite sets, there is a set $D \subseteq A$ such that $\#(D) = \#(A)$ and $\langle I_\xi\rangle_{\xi\in D}$ is a Δ-system. (Kunen 80, II.1.6; Just & Weese 97, Theorem 16.3. For the present volume we need only the case $\#(A) = \omega_1$, which is treated in Jech 78, p. 225.)

4A1E Free sets (a) Let A be a set of cardinal at least ω_2, and $\langle J_\xi\rangle_{\xi\in A}$ a family of countable sets. Then there are distinct ξ, $\eta \in A$ such that $\xi \notin J_\eta$ and $\eta \notin J_\xi$. **P** Let $K \subseteq A$ be a set of cardinal ω_1, and set $L = K \cup \bigcup_{i\in K} J_i$. Then L has cardinal ω_1, so there is a $\xi \in A \setminus L$. Now there is an $\eta \in K \setminus J_\xi$, and this pair (ξ, η) serves. **Q**

(b) If $\langle K_\xi\rangle_{\xi\in A}$ is a disjoint family of sets indexed by an uncountable subset A of ω_1, and $\langle J_\eta\rangle_{\eta<\omega_1}$ is a family of countable sets, there is an uncountable $B \subseteq A$ such that $K_\xi \cap J_\eta = \emptyset$ whenever η, $\xi \in B$ and $\eta < \xi$. **P** Choose $\langle \xi_\zeta\rangle_{\zeta<\omega_1}$ inductively in such a way that $\xi_\zeta \in A$ and $K_{\xi_\zeta} \cap J_{\xi_\eta} = \emptyset$, $\xi_\zeta > \xi_\eta$ for every $\eta < \xi$. Set $B = \{\xi_\zeta : \zeta < \omega_1\}$. **Q**

4A1F Selecting subsequences (a) Let $\langle K_i\rangle_{i\in I}$ be a countable family of sets such that $\bigcap_{i\in J} K_i$ is infinite for every finite subset J of I. Then there is an infinite set K such that $K \setminus K_i$ is finite and $K_i \setminus K$ is infinite for every $i \in I$. **P** We can suppose that $I \subseteq \mathbb{N}$. Choose $\langle k_n\rangle_{n\in\mathbb{N}}$ inductively such that $k_n \in \bigcap_{i\in I, i\le n} K_i \setminus \{k_i : i < n\}$ for every $n \in \mathbb{N}$, and set $K = \{k_{2n} : n \in \mathbb{N}\}$. **Q**

Consequently there is a family $\langle K_\xi\rangle_{\xi<\omega_1}$ of infinite subsets of $\mathbb{N}$ such that $K_\xi \setminus K_\eta$ is finite if $\eta \le \xi$, infinite if $\xi < \eta$. (Choose the K_ξ inductively.)

(b) Let $\langle \mathcal{J}_i\rangle_{i\in I}$ be a countable family of subsets of $[\mathbb{N}]^\omega$ such that $\mathcal{J}_i \cap \mathcal{P}K \neq \emptyset$ for every $K \in [\mathbb{N}]^\omega$ and $i \in I$. Then there is an infinite $K \subseteq \mathbb{N}$ such that for every $i \in I$ there is a $J \in \mathcal{J}_i$ such that $K \setminus J$ is finite. **P** The case $I = \emptyset$ is trivial; suppose that $\langle i_n\rangle_{n\in\mathbb{N}}$ runs over I. Choose K_n, k_n inductively, for $n \in \mathbb{N}$, by taking

$$K_0 = \mathbb{N}, \quad k_n \in K_n,$$

$$K_{n+1} \subseteq K_n \setminus \{k_n\}, \quad K_{n+1} \in \mathcal{J}_{i_n}$$

for every n; set $K = \{k_n : n \in \mathbb{N}\}$. **Q**

4A1G Ramsey's Theorem If $n \in \mathbb{N}$, K is finite and $h : [\mathbb{N}]^n \to K$ is any function, there is an infinite $I \subseteq \mathbb{N}$ such that h is constant on $[I]^n$. (BOLLOBÁS 79, p. 105, Theorem 3; JECH 78, 29.1; JUST & WEESE 97, 15.3; LEVY 79, IX.3.7. For the present volume we need only the case $n = \#(K) = 2$.)

4A1H The Marriage Lemma again In 449J it will be useful to have an infinitary version of the Marriage Lemma available.

Proposition Let X and Y be sets, and $R \subseteq X \times Y$ a set such that $R[\{x\}]$ is finite for every $x \in X$ and $\#(R[I]) \geq \#(I)$ for every finite set $I \subseteq X$. Then there is an injective function $f : X \to Y$ such that $(x, f(x)) \in R$ for every $x \in X$.

proof For each finite $J \subseteq X$ there is an injective function $f_J : J \to Y$ such that $f_J \subseteq R$ (identifying f_J with its graph), by the ordinary Marriage Lemma (3A1K) applied to $R \cap (J \times R[J])$. Let $\mathcal{F}$ be any ultrafilter on $[X]^{<\omega}$ containing $\{J : I \subseteq J \in [X]^{<\omega}\}$ for every $I \in [X]^{<\omega}$; then for each $x \in X$ there must be an $f(x) \in R[\{x\}]$ such that $\{J : f_J(x) = f(x)\} \in \mathcal{F}$, because $R[\{x\}]$ is finite. Now $f \subseteq R$ is a function from X to Y and must be injective, because for any x, $x' \in X$ there is a $J \in [X]^{<\omega}$ such that f and f_J agree on $\{x, x'\}$.

4A1I Filters (a) Let X be a non-empty set. If $\mathcal{E} \subseteq \mathcal{P}X$ is non-empty and has the finite intersection property,

$$\mathcal{F} = \{A : A \subseteq X,\ A \supseteq \bigcap \mathcal{E}' \text{ for some non-empty finite } \mathcal{E}' \subseteq \mathcal{E}\}$$

is the smallest filter on X including $\mathcal{E}$, the filter **generated** by $\mathcal{E}$.

If $\mathcal{E} \subseteq \mathcal{P}X$ is non-empty and downwards-directed, then it has the finite intersection property iff it does not contain $\emptyset$; in this case we say that $\mathcal{E}$ is a **filter base**; $\mathcal{F} = \{A : A \subseteq X,\ A \supseteq E \text{ for some } E \in \mathcal{E}\}$, and $\mathcal{E}$ is a base for the filter $\mathcal{F}$.

In general, if $\mathcal{E}$ is a family of subsets of a non-empty set X, then there is a filter on X including $\mathcal{E}$ iff $\mathcal{E}$ has the finite intersection property; in this case, there is an ultrafilter on X including $\mathcal{E}$ (2A1O).

(b) If κ is a cardinal and $\mathcal{F}$ is a filter then $\mathcal{F}$ is **κ-complete** if $\bigcap \mathcal{E} \in \mathcal{F}$ whenever $\mathcal{E} \subseteq \mathcal{F}$ and $0 < \#(\mathcal{E}) < \kappa$. Every filter is ω-complete.

(c) A filter $\mathcal{F}$ on a regular uncountable cardinal κ is **normal** if (i) $\kappa \setminus \xi \in \mathcal{F}$ for every $\xi < \kappa$ (ii) whenever $\langle F_\xi \rangle_{\xi<\kappa}$ is a family in $\mathcal{F}$, its diagonal intersection belongs to $\mathcal{F}$.

4A1J Lemma A normal filter $\mathcal{F}$ on a regular uncountable cardinal κ is κ-complete.

proof If $\lambda < \kappa$ and $\langle F_\xi \rangle_{\xi<\lambda}$ is a family in $\mathcal{F}$, set $F_\xi = \kappa$ for $\lambda \leq \xi < \kappa$, and let F be the diagonal intersection of $\langle F_\xi \rangle_{\xi<\kappa}$; then $\bigcap_{\xi<\lambda} F_\xi \supseteq F \setminus \lambda$ belongs to $\mathcal{F}$.

4A1K Theorem Let X be a set and $\mathcal{F}$ a non-principal ω_1-complete ultrafilter on X. Let κ be the least cardinal of any non-empty set $\mathcal{E} \subseteq \mathcal{F}$ such that $\bigcap \mathcal{E} \notin \mathcal{F}$. Then κ is a regular uncountable cardinal, $\mathcal{F}$ is κ-complete, and there is a function $g : X \to \kappa$ such that $g[[\mathcal{F}]]$ is a normal ultrafilter on κ.

proof (a) By the definition of κ, $\mathcal{F}$ is κ-complete. Because $\mathcal{F}$ is ω_1-complete, $\kappa > \omega$. Let H be the set of all functions $h : X \to \kappa$ such that $h^{-1}[\kappa \setminus \xi] \in \mathcal{F}$ for every $\xi < \kappa$. Then H is not empty. **P** Let $\langle E_\xi \rangle_{\xi<\kappa}$ be a family in $\mathcal{F}$ such that $E = \bigcap_{\xi<\kappa} E_\xi \notin \mathcal{F}$. Because $\mathcal{F}$ is an ultrafilter, $X \setminus E \in \mathcal{F}$. Set $h(x) = 0$ if $x \in E$, $h(x) = \min\{\xi : x \notin E_\xi\}$ if $x \in X \setminus E$; then

$$h^{-1}[\kappa \setminus \xi] \supseteq (X \setminus E) \cap \bigcap_{\eta<\xi} E_\eta \in \mathcal{F}$$

for every $\xi < \kappa$, because $\mathcal{F}$ is κ-complete, so $h \in H$. **Q**

(b) For h, $h' \in H$, say that $h \prec h'$ if $\{x : h(x) < h'(x)\} \in \mathcal{F}$. Then there is a $g \in H$ such that $h \not\prec g$ for any $h \in H$. **P?** Otherwise, there is a sequence $\langle h_n \rangle_{n\in\mathbb{N}}$ in H such that $h_{n+1} \prec h_n$ for every $n \in \mathbb{N}$. Then $E_n = \{x : h_{n+1}(x) < h_n(x)\} \in \mathcal{F}$ for every n. Because $\mathcal{F}$ is ω_1-complete, there is an $x \in \bigcap_{n\in\mathbb{N}} E_n$; but now $\langle h_n(x) \rangle_{n\in\mathbb{N}}$ is a strictly decreasing sequence of ordinals, which is impossible. **XQ**

(c) I should check that κ is regular. **P** If $\langle\alpha_\xi\rangle_{\xi<\lambda}$ is any family in κ with $\lambda<\kappa$, then $g^{-1}[\kappa\setminus\alpha_\xi]\in\mathcal{F}$ for every ξ, so (because $\mathcal{F}$ is κ-complete)

$$g^{-1}[\kappa\setminus\sup_{\xi<\lambda}\alpha_\xi]=\bigcap_{\xi<\lambda}g^{-1}[\kappa\setminus\alpha_\xi]\in\mathcal{F},$$

and $\sup_{\xi<\lambda}\alpha_\xi\neq\kappa$. **Q**

(d) The image filter $g[[\mathcal{F}]]$ is an ultrafilter on κ, by 2A1N. Because $g\in H$, $g^{-1}[\kappa\setminus\xi]\in\mathcal{F}$ and $\kappa\setminus\xi\in g[[\mathcal{F}]]$ for any $\xi<\kappa$. **?** Suppose, if possible, that $g[[\mathcal{F}]]$ is not normal. Then there is a family $\langle A_\xi\rangle_{\xi<\kappa}$ in $g[[\mathcal{F}]]$ such that its diagonal intersection A does not belong to $g[[\mathcal{F}]]$, that is, $g^{-1}[A]\notin\mathcal{F}$ and $X\setminus g^{-1}[A]\in\mathcal{F}$. Define $h:X\to\kappa$ by setting

$$\begin{aligned}h(x)&=0 \text{ if } g(x)\in A\\ &=\min\{\eta:\eta<g(x),\ g(x)\notin A_\eta\} \text{ if } g(x)\notin A.\end{aligned}$$

Then

$$h^{-1}[\kappa\setminus\xi]\supseteq(X\setminus g^{-1}[A])\cap\textstyle\bigcap_{\eta<\xi}g^{-1}[A_\eta]\in\mathcal{F}$$

for every $\xi<\kappa$. Thus $h\in H$. But also $h(x)<g(x)$ for every $x\in X\setminus g^{-1}[A]$, so $h\prec g$, contrary to the choice of g. **X**

Thus $g[[\mathcal{F}]]$ is a normal filter, and the theorem is proved.

4A1L Theorem Let κ be a regular uncountable cardinal, and $\mathcal{F}$ a normal ultrafilter on κ. If $S\subseteq[\kappa]^{<\omega}$, there is a set $F\in\mathcal{F}$ such that, for each $n\in\mathbb{N}$, $[F]^n$ is either a subset of S or disjoint from S. (Jech 78, Theorem 70; Just & Weese 97, Corollary 23.18; Levy 79, IX.4.30. Compare 4A1G.)

4A1M Ostaszewski's ♣ This is the statement

> Let Ω be the family of non-zero countable limit ordinals. Then there is a family $\langle\theta_\xi(n)\rangle_{\xi\in\Omega,n\in\mathbb{N}}$ such that (i) for each $\xi\in\Omega$, $\langle\theta_\xi(n)\rangle_{n\in\mathbb{N}}$ is a strictly increasing sequence with supremum ξ (ii) for any uncountable $A\subseteq\omega_1$ there is a $\xi\in\Omega$ such that $\theta_\xi(n)\in A$ for every $n\in\mathbb{N}$.

This is an immediate consequence of Jensen's $\diamondsuit$ (Just & Weese 97, Exercise 22.9), which is itself a consequence of Gödel's Axiom of Constructibility (Kunen 80, §II.7; Jech 78, §22; Just & Weese 97, §22).

4A1N Lemma Assume ♣. Then there is a family $\langle C_\xi\rangle_{\xi<\omega_1}$ of sets such that (i) $C_\xi\subseteq\xi$ for every $\xi<\omega_1$ (ii) $C_\xi\cap\eta$ is finite whenever $\eta<\xi<\omega_1$ (iii) for any uncountable sets A, $B\subseteq\omega_1$ there is a $\xi<\omega_1$ such that $A\cap C_\xi$ and $B\cap C_\xi$ are both infinite.

proof (a) Let $\langle\theta_\xi(n)\rangle_{\xi\in\Omega,n\in\mathbb{N}}$ be a family as in 4A1M. Let $f:\omega_1\to[\omega_1]^2$ be a surjection (3A1Cd). For $\xi\in\Omega$, set

$$C_\xi=\textstyle\bigcup_{i\in\mathbb{N}}f(\theta_\xi(i+1))\cap\xi\setminus\theta_\xi(i).$$

Then $C_\xi\subseteq\xi$, and if $\eta<\xi$ there is some $n\in\mathbb{N}$ such that $\theta_\xi(n)\geq\eta$, so that

$$C_\xi\cap\eta\subseteq\textstyle\bigcup_{i\leq n}f(\theta_\xi(i))$$

is finite. For $\xi\in\omega_1\setminus\Omega$ set $C_\xi=\emptyset$. Then $\langle C_\xi\rangle_{\xi<\omega_1}$ satisfies (i) and (ii) above.

(b) Now suppose that A, $B\subseteq\omega_1$ are uncountable. Choose $\langle\alpha_\xi\rangle_{\xi<\omega_1}$, $\langle\beta_\xi\rangle_{\xi<\omega_1}$, $\langle I_\xi\rangle_{\xi<\omega_1}$ inductively, as follows. β_ξ is to be the smallest ordinal such that $\{\alpha_\eta:\eta<\xi\}\cup\bigcup_{\eta<\xi}I_\eta\subseteq\beta_\xi$; I_ξ is to be a doubleton subset of $\omega_1\setminus(\beta_\xi\cup\bigcup_{\eta\leq\beta_\xi}f(\eta))$ meeting both A and B; and $\alpha_\xi<\omega_1$ is to be such that $f(\alpha_\xi)=I_\xi$. Set $D=\{\alpha_\xi:\xi<\omega_1\}$. This construction ensures that $\langle\alpha_\xi\rangle_{\xi<\omega_1}$ and $\langle\beta_\xi\rangle_{\xi<\omega_1}$ are strictly increasing, with $\beta_\xi<\alpha_\xi<\beta_{\xi+1}$ for every ξ, so that $f(\delta)$ meets both A and B for every $\delta\in D$, while $f(\delta)\subseteq\delta'$ and $f(\delta')\cap f(\delta)=\emptyset$ whenever $\delta<\delta'$ in D.

By the choice of $\langle\theta_\xi(n)\rangle_{\xi\in\Omega,n\in\mathbb{N}}$, there is a $\xi\in\Omega$ such that $\theta_\xi(n)\in D$ for every $n\in\mathbb{N}$. But this means that

$$f(\theta_\xi(i))\subseteq\theta_\xi(i+1)\subseteq\xi,\quad f(\theta_\xi(i+1))\cap f(\theta_\xi(i))=\emptyset$$

for every $i\in\mathbb{N}$, so $C_\xi=\bigcup_{i\in\mathbb{N}}f(\theta_\xi(i))$ meets both A and B in infinite sets.

4A1O The size of σ-algebras: Proposition Let $\mathfrak{A}$ be a Boolean algebra, B a subset of $\mathfrak{A}$, and $\mathfrak{B}$ the σ-subalgebra of $\mathfrak{A}$ generated by B (331E). Then $\#(\mathfrak{B}) \leq \max(4, \#(B^{\mathbb{N}}))$. In particular, if $\#(B) \leq \mathfrak{c}$ then $\#(\mathfrak{B}) \leq \mathfrak{c}$.

proof (a) If $\#(B) \leq 1$, this is trivial, since then $\#(\mathfrak{B}) \leq 4$. So we need consider only the case $\#(B) \geq 2$.

(b) Set $\kappa = \#(B^{\mathbb{N}})$; then whenever $\#(A) \leq \kappa$, that is, there is an injection from A to $B^{\mathbb{N}}$, then

$$\#(A^{\mathbb{N}}) \leq \#((B^{\mathbb{N}})^{\mathbb{N}}) = \#(B^{\mathbb{N}\times\mathbb{N}}) = \#(B^{\mathbb{N}}) = \kappa.$$

As we are supposing that B has more than one element, $\kappa \geq \#(\{0,1\}^{\mathbb{N}}) = \mathfrak{c} \geq \omega_1$.

(c) Define $\langle B_\xi\rangle_{\xi<\omega_1}$ inductively, as follows. $B_0 = B \cup \{0\}$. Given $\langle B_\eta\rangle_{\eta<\xi}$, where $0 < \xi < \omega_1$, set $B'_\xi = \bigcup_{\eta<\xi} B_\eta$ and

$$\begin{aligned} B_\xi = &\{1 \setminus b : b \in B'_\xi\} \\ &\cup \{\sup_{n\in\mathbb{N}} b_n : \langle b_n\rangle_{n\in\mathbb{N}} \text{ is a sequence in } B'_\xi \text{ with a supremum in } \mathfrak{A}\}; \end{aligned}$$

continue.

An easy induction on ξ (relying on 3A1Cc and (b) above) shows that every B_ξ has cardinal at most κ. So $C = \bigcup_{\xi<\omega_1} B_\xi$ has cardinal at most κ.

(d) Now $\langle B_\xi\rangle_{\xi<\omega_1}$ is a non-decreasing family, so if $\langle c_n\rangle_{n\in\mathbb{N}}$ is any sequence in C there is some $\xi < \omega_1$ such that every c_n belongs to $B_\xi \subseteq B'_{\xi+1}$. But this means that if $\sup_{n\in\mathbb{N}} c_n$ is defined in $\mathfrak{A}$, it belongs to $B_{\xi+1} \subseteq C$. At the same time,

$$1 \setminus c_0 \in B_{\xi+1} \subseteq C.$$

This shows that C is closed under complementation and countable suprema; since it contains 0, it is a σ-subalgebra of $\mathfrak{A}$; since it includes B, it includes $\mathfrak{B}$, and $\#(\mathfrak{B}) \leq \#(C) \leq \kappa$, as claimed.

(d) Finally, if $\#(B) \leq \mathfrak{c} = \#(\{0,1\}^{\mathbb{N}})$, then

$$\#(\mathfrak{B}) \leq \kappa \leq \#(\{0,1\}^{\mathbb{N}\times\mathbb{N}}) = \mathfrak{c}.$$

4A1P An incidental fact If I is a countable set and $\epsilon > 0$, there is a family $\langle\epsilon_i\rangle_{i\in I}$ of strictly positive real numbers such that $\sum_{i\in I} \epsilon_i \leq \epsilon$. **P** Let $f : I \to \mathbb{N}$ be an injection and set $\epsilon_i = 2^{-f(i)-1}\epsilon$. **Q**

4A2 General topology

Even more than in previous volumes, naturally enough, the work of this volume depends on results from general topology. We have now reached the point where some of the facts I rely on are becoming hard to find as explicitly stated theorems in standard textbooks. I find myself therefore writing out rather a lot of proofs. You should not suppose that the results to which I attach proofs, rather than references, are particularly deep; on the contrary, in many cases I am merely spelling out solutions to classic exercises.

The style of 'general' topology, as it has evolved over the last ninety years, is to develop a language capable of squeezing the utmost from every step of argument. While this does sometimes lead to absurdly obscure formulations, it remains a natural, and often profitable, response to the remarkably dense network of related ideas in this area. I therefore follow the spirit of the subject in giving the results I need in the full generality achievable within the terminology I use. For the convenience of anyone coming to the theory for the first time, I repeat some of them in the forms in which they are actually applied. I should remark, however, that in some cases materially stronger results can be proved with little extra effort; as always, this appendix is to be thought of not as a substitute for a thorough study of the subject, but as a guide connecting standard approaches to the general theory with the special needs of this volume.

4A2A Definitions I begin the section with a glossary of terms not defined elsewhere.

Base of neighbourhoods If X is a topological space and $x \in X$, a **base of neighbourhoods** of x is a family $\mathcal{V}$ of neighbourhoods of x such that every neighbourhood of x includes some member of $\mathcal{V}$.

boundary If X is a topological space and $A \subseteq X$, the **boundary** of A is $\partial A = \overline{A} \setminus \operatorname{int} A$.

Čech-complete A completely regular Hausdorff topological space X is **Čech-complete** if it is homeomorphic to a G_δ subset of a compact Hausdorff space.

closed interval Let X be a totally ordered set. A **closed interval** in X is an interval of one of the forms $[x, y]$, $]-\infty, y]$, $[x, \infty[$ or $X =]-\infty, \infty[$ where x, $y \in X$ (see the definition of 'interval' below); for definiteness, let me say that I count $\emptyset$ as a 'closed interval'.

coarser topology If $\mathfrak{S}$ and $\mathfrak{T}$ are two topologies on a set X, we say that $\mathfrak{S}$ is **coarser** than $\mathfrak{T}$ if $\mathfrak{S} \subseteq \mathfrak{T}$.

compact support Let X be a topological space and $f : X \to \mathbb{R}$ a function. I say that f has **compact support** if $\overline{\{x : x \in X, f(x) \neq 0\}}$ is compact in X.

countably compact A topological space X is **countably compact** if every countable open cover of X has a finite subcover. (**Warning!** some authors reserve the term for Hausdorff spaces.) A subset of a topological space is countably compact if it is countably compact in its subspace topology.

countably paracompact A topological space X is **countably paracompact** if given any countable open cover $\mathcal{G}$ of X there is a locally finite family $\mathcal{H}$ of open sets which refines $\mathcal{G}$ and covers X.

countably tight A topological space X is **countably tight** (or has **countable tightness**) if whenever $A \subseteq X$ and $x \in \overline{A}$ there is a countable set $B \subseteq A$ such that $x \in \overline{B}$.

direct sum, disjoint union Let $\langle (X_i, \mathfrak{T}_i) \rangle_{i \in I}$ be a family of topological spaces, and set $X = \{(x, i) : i \in I, x \in X_i\}$. The **disjoint union topology** on X is $\mathfrak{T} = \{G : G \subseteq X, \{x : (x, i) \in G\} \in \mathfrak{T}_i \text{ for every } i \in I\}$; $(X, \mathfrak{T})$ is the **(direct) sum** of $\langle (X_i, \mathfrak{T}_i) \rangle_{i \in I}$.

If X is a set, $\langle X_i \rangle_{i \in I}$ a partition of X, and $\mathfrak{T}_i$ a topology on X_i for every $i \in I$, then the **disjoint union topology** or **sum topology** on X is $\{G : G \subseteq X, G \cap X_i \in \mathfrak{T}_i \text{ for every } i \in I\}$.

dyadic A Hausdorff space is **dyadic** if it is a continuous image of $\{0, 1\}^I$ for some set I.

finer topology If $\mathfrak{S}$ and $\mathfrak{T}$ are two topologies on a set X, we say that $\mathfrak{S}$ is **finer** than $\mathfrak{T}$ if $\mathfrak{S} \supseteq \mathfrak{T}$.

first-countable A topological space X is **first-countable** if every point has a countable base of neighbourhoods.

half-open Let X be a totally ordered set. A **half-open interval** in X is a set of one of the forms $[x, y[$, $]x, y]$ where x, $y \in X$ and $x < y$ (see the definition of 'interval' below).

hereditarily Lindelöf A topological space is **hereditarily Lindelöf** if every subspace is Lindelöf.

hereditarily metacompact A topological space is **hereditarily metacompact** if every subspace is metacompact.

indiscrete If X is any set, the **indiscrete** topology on X is the topology $\{\emptyset, X\}$.

interval Let $(X, \leq)$ be a totally ordered set. Adjoin points ∞, $-\infty$ to X and extend $\leq$ to a total order on $X \cup \{-\infty, \infty\}$ by declaring that $-\infty < x < \infty$ for every $x \in X$. For u, $v \in X \cup \{-\infty, \infty\}$, set $]u, v[= \{x : u < x < v\}$, $[u, v] = \{x : u \leq x \leq v\}$, $]u, v] = \{x : u < x \leq v\}$, $[u, v[= \{x : u \leq x < v\}$; call sets of these forms **intervals**. Note that if X is not Dedekind complete then not every set which is order-convex in the sense of 351Xb will be an 'interval' in this sense.

isolated If X is a topological space, a family $\mathcal{A}$ of subsets of X is **isolated** if $A \cap \overline{\bigcup(\mathcal{A} \setminus \{A\})}$ is empty for every $A \in \mathcal{A}$; that is, if $\mathcal{A}$ is disjoint and every member of $\mathcal{A}$ is a relatively open set in $\bigcup \mathcal{A}$.

Lindelöf A topological space is **Lindelöf** if every open cover has a countable subcover. (**Warning!** some authors reserve the term for regular spaces.)

locally finite If X is a topological space, a family $\mathcal{A}$ of subsets of X is **locally finite** if for every $x \in X$ there is an open set which contains x and meets only finitely many members of $\mathcal{A}$.

lower semi-continuous If X is a topological space and Y a totally ordered set, a function $f : X \to Y$ is **lower semi-continuous** if $\{x : f(x) > y\}$ is open for every $y \in Y$. (Cf. 225H, 3A3Cf.)

metacompact A topological space is **metacompact** if every open cover has a point-finite refinement which is an open cover. (**Warning!** some authors reserve the term for Hausdorff spaces.)

neighbourhood If X is a topological space and $x \in X$, a **neighbourhood** of x is any subset of X including an open set which contains x.

network Let $(X, \mathfrak{T})$ be a topological space. A **network** for $\mathfrak{T}$ is a family $\mathcal{E} \subseteq \mathcal{P}X$ such that whenever $x \in G \in \mathfrak{T}$ there is an $E \in \mathcal{E}$ such that $x \in E \subseteq G$.

normal A topological space X is **normal** if for any disjoint closed sets E, $F \subseteq X$ there are disjoint open sets G, H such that $E \subseteq G$ and $F \subseteq H$. (**Warning!** some authors reserve the term for Hausdorff spaces.)

open interval Let X be a totally ordered set. An **open interval** in X is a set of the form $]u, v[$ where u, $v \in X \cup \{-\infty, \infty\}$ (see the definition of 'interval' above).

open map If $(X, \mathfrak{T})$ and $(Y, \mathfrak{S})$ are topological spaces, a function $f : X \to Y$ is **open** if $f[G] \in \mathfrak{S}$ for every $G \in \mathfrak{T}$.

order topology Let $(X, \leq)$ be a totally ordered set. Its **order topology** is that generated by sets of the form $]x, \infty[= \{y : y > x\}$, $]-\infty, x[= \{y : y < x\}$ as x runs over X.

paracompact A topological space is **paracompact** if every open cover has a locally finite refinement which is an open cover. (**Warning!** some authors reserve the term for Hausdorff spaces.)

perfectly normal A topological space is **perfectly normal** if it is normal and every closed set is a G_δ set. (**Warning!** remember that some authors reserve the term 'normal' for Hausdorff spaces.)

point-countable, point-finite A family $\mathcal{A}$ of sets is **point-countable** if no point belongs to more than countably many members of $\mathcal{A}$. Similarly, an indexed family $\langle A_i \rangle_{i \in I}$ of sets is **point-finite** if $\{i : x \in A_i\}$ is finite for every x.

Polish A topological space X is **Polish** if it is separable and its topology can be defined from a metric under which X is complete.

pseudometrizable A topological space $(X, \mathfrak{T})$ is **pseudometrizable** if $\mathfrak{T}$ is defined by a single pseudometric (2A3F).

refine(ment) If $\mathcal{A}$ is a family of sets, a **refinement** of $\mathcal{A}$ is a family $\mathcal{B}$ of sets such that every member of $\mathcal{B}$ is included in some member of $\mathcal{A}$; in this case I say that $\mathcal{B}$ **refines** $\mathcal{A}$. (**Warning!** I do not suppose that $\bigcup \mathcal{B} = \bigcup \mathcal{A}$.)

relatively countably compact If X is a topological space, a subset A of X is **relatively countably compact** if every sequence in A has a cluster point in X. (**Warning!** This is *not* the same as supposing that A is included in a countably compact subset of X.)

scattered A topological space X is **scattered** if every non-empty subset of X has an isolated point (in its subspace topology).

second-countable A topological space is **second-countable** if the topology has a countable base, that is, if its weight is at most ω.

semi-continuous *see* lower semi-continuous, upper semi-continuous.

separately continuous Let $\langle X_i \rangle_{i \in I}$ be a family of topological spaces with product X, and Y another topological space. Then a function $f : X \to Y$ is **separately continuous** if for every $j \in I$ and $z \in \prod_{i \in I \setminus \{j\}} X_i$ the function $t \mapsto f(z^\frown t) : X_j \to Y$ is continuous, where $z^\frown t$ is the member of X extending z and such that $(z^\frown t)(j) = t$.

sequential A topological space is **sequential** if every sequentially closed set in X is closed.

sequentially closed If X is a topological space, a subset A of X is **sequentially closed** if $x \in A$ whenever $\langle x_n \rangle_{n \in \mathbb{N}}$ is a sequence in A converging to $x \in X$.

sequentially compact A topological space is **sequentially compact** if every sequence has a convergent sequence. A subset of a topological space is sequentially compact if it is sequentially compact in its subspace topology. (**Warning!** some authors reserve the term for Hausdorff spaces.)

sequentially continuous If X and Y are topological spaces, a function $f : X \to Y$ is **sequentially continuous** if $\langle f(x_n) \rangle_{n \in \mathbb{N}} \to f(x)$ in Y whenever $\langle x_n \rangle_{n \in \mathbb{N}} \to x$ in X.

subbase If $(X, \mathfrak{T})$ is a topological space, a **subbase** for $\mathfrak{T}$ is a family $\mathcal{U} \subseteq \mathfrak{T}$ which generates $\mathfrak{T}$, in the sense that $\mathfrak{T}$ is the coarsest topology on X including $\mathcal{U}$. (**Warning!** most authors reserve the term for families $\mathcal{U}$ with union X.)

totally bounded If $(X, \mathcal{W})$ is a uniform space, a subset A of X is **totally bounded** if for every $W \in \mathcal{W}$ there is a finite set $I \subseteq X$ such that $A \subseteq W[I]$. If (X, ρ) is a metric space, a subset of X is totally bounded if it is totally bounded for the associated uniformity (3A4B).

uniform convergence If X is a set and $\mathcal{A}$ is a family of subsets of X then the **topology of uniform convergence** on members of $\mathcal{A}$ is the topology on $\mathbb{R}^X$ generated by the pseudometrics $(f, g) \mapsto \min(1, \sup_{x \in A} |f(x) - g(x)|)$ as A runs through $\mathcal{A} \setminus \{\emptyset\}$. (It is elementary to verify that the formula here defines a pseudometric.)

upper semi-continuous If X is a topological space, a function $f : X \to \mathbb{R}$ is **upper semi-continuous** if $\{x : f(x) < \alpha\}$ is open for every $\alpha \in \mathbb{R}$.

weakly α-favourable A topological space $(X,\mathfrak{T})$ is **weakly α-favourable** if there is a function $\sigma : \bigcup_{n\in\mathbb{N}}(\mathfrak{T}\setminus\{\emptyset\})^{n+1}\to\mathfrak{T}\setminus\{\emptyset\}$ such that (i) $\sigma(G_0,\dots,G_n)\subseteq G_n$ whenever $G_0,\dots,G_n$ are non-empty open sets (ii) whenever $\langle G_n\rangle_{n\in\mathbb{N}}$ is a sequence in $\mathfrak{T}\setminus\{\emptyset\}$ such that $G_{n+1}\subseteq\sigma(G_0,\dots,G_n)$ for every n, then $\bigcap_{n\in\mathbb{N}}G_n$ is non-empty.

weight If X is a topological space, its **weight** $w(X)$ is the smallest cardinal of any base for the topology.

F_σ If X is a topological space, an $\mathbf{F}_\sigma$ set in X is one expressible as the union of a sequence of closed sets.

G_δ If X is a topological space, a $\mathbf{G}_\delta$ set in X is one expressible as the intersection of a sequence of open sets.

K_σ If X is a topological space, a $\mathbf{K}_\sigma$ set in X is one expressible as the union of a sequence of compact sets.

lim sup If $\langle A_i\rangle_{i\in I}$ is a non-empty family of sets in a topological space and $\mathcal{F}$ is a filter on I, I write $\limsup_{i\to\mathcal{F}}A_i$ for $\bigcap_{J\in\mathcal{F}}\overline{\bigcup_{i\in J}A_i}$.

$\mathcal{P}X$ If X is any set, the **usual topology** on $\mathcal{P}X$ is that generated by the sets $\{A : A\cap J = K\}$ where $J\subseteq X$ is finite and $K\subseteq J$.

T_0 If $(X,\mathfrak{T})$ is a topological space, we say that it is $\mathbf{T}_0$ if for any two distinct points of X there is an open set containing one but not the other.

T_1 If $(X,\mathfrak{T})$ is a topological space, we say that it is $\mathbf{T}_1$ if $\{x\}$ is a closed set for every $x\in X$.

π-base If $(X,\mathfrak{T})$ is a topological space, a **π-base** for $\mathfrak{T}$ is a set $\mathcal{U}\subseteq\mathfrak{T}$ such that every non-empty open set includes a non-empty member of $\mathcal{U}$.

σ-compact A topological space X is **σ-compact** if there is a sequence of compact sets covering X.

σ-disjoint A family $\mathcal{A}$ of sets is **σ-disjoint** if it is expressible as $\bigcup_{n\in\mathbb{N}}\mathcal{A}_n$ where every $\mathcal{A}_n$ is disjoint.

σ-isolated If X is a topological space, a family of subsets of X is **σ-isolated** if it is expressible as $\bigcup_{n\in\mathbb{N}}\mathcal{A}_n$ where every $\mathcal{A}_n$ is an isolated family.

σ-metrically-discrete If (X,ρ) is a metric space, a family $\mathcal{A}$ of subsets of X is **σ-metrically-discrete** if it is expressible as $\bigcup_{n\in\mathbb{N}}\mathcal{A}_n$ where $\rho(x,y)\geq 2^{-n}$ whenever $n\in\mathbb{N}$, A and B are distinct members of $\mathcal{A}_n$, $x\in A$ and $y\in B$.

4A2B Elementary facts about general topological spaces (a) Bases and networks (i) Let $(X,\mathfrak{T})$ be a topological space and $\mathcal{U}$ a subbase for $\mathfrak{T}$. Then $\{X\}\cup\{U_0\cap U_1\cap\ldots\cap U_n : U_0,\dots,U_n\in\mathcal{U}\}$ is a base for $\mathfrak{T}$. (For this is a base for a topology, by 3A3Mc.)

(ii) Let X and Y be topological spaces, and $\mathcal{V}$ a subbase for the topology of Y. Then a function $f : X\to Y$ is continuous iff $f^{-1}[V]$ is open for every $V\in\mathcal{V}$. (Engelking 89, 1.4.1(ii)).

(iii) If X and Y are topological spaces, $\mathcal{E}$ is a network for the topology of Y, and $f : X\to Y$ is a function such that $f^{-1}[E]$ is open for every $E\in\mathcal{E}$, then f is continuous. (The topology generated by $\mathcal{E}$ includes the given topology on Y.)

(iv) If $\mathcal{U}$ is a (sub-)base for a topology on X, and $Y\subseteq X$, then $\{Y\cap U : U\in\mathcal{U}\}$ is a (sub-)base for the subspace topology of Y. (Császár 78, 2.3.13(e)-(f).)

(v) If X is a topological space and $\mathcal{U}$ is a subbase for the topology of X, then a filter $\mathcal{F}$ on X converges to $x\in X$ iff $\{U : x\in U\in\mathcal{U}\}\subseteq\mathcal{F}$. (If the condition is satisfied, $\mathcal{F}\cup\{A : A\subseteq X,\ x\notin A\}$ is a topology on X including $\mathcal{U}$.)

(vi) If X and Y are topological spaces with subbases $\mathcal{U}$, $\mathcal{V}$ respectively, then $\{U\times Y : U\in\mathcal{U}\}\cup\{X\times V : V\in\mathcal{V}\}$ is a subbase for the product topology of $X\times Y$. (Kuratowski 66, §15.I.)

(vii) If X is a topological space, $\mathcal{E}$ is a network for the topology of X, and Y is a subset of X, then $\{E\cap Y : E\in\mathcal{E}\}$ is a network for the topology of Y.

(viii) If X is a topological space and $\mathcal{A}$ is a (σ-)isolated family of subsets of X, then $\{A\cap Y : A\in\mathcal{A}'\}$ is (σ-)isolated whenever $Y\subseteq X$ and $\mathcal{A}'\subseteq\mathcal{A}$.

(ix) If a topological space X has a σ-isolated network, so does every subspace of X.

(b) If $\langle H_i\rangle_{i\in I}$ is a partition of a topological space X into open sets and $F_i\subseteq H_i$ is closed (either in X or in H_i) for each $i\in I$, then $F=\bigcup_{i\in I}F_i$ is closed in X. ($X\setminus F=\bigcup_{i\in I}(H_i\setminus F_i)$.)

(c) If X is a topological space, $A\subseteq X$ and $x\in X$, then $x\in\overline{A}$ iff there is an ultrafilter on X, containing A, which converges to x. ($\{A\}\cup\{G : x\in G\subseteq X,\ G\text{ is open}\}$ has the finite intersection property; use 4A1Ia.)

(d) Semi-continuity Let X be a topological space.

(i) A function $f : X \to \mathbb{R}$ is lower semi-continuous iff $-f$ is upper semi-continuous. (Čech 66, 18D.8.)

(ii) If $f : X \to \mathbb{R}$ is lower semi-continuous, Y is another topological space, and $g : Y \to X$ is continuous, then $fg : Y \to \mathbb{R}$ is lower semi-continuous. ($\{y : (fg)(y) > \alpha\} = g^{-1}[\{x : f(x) > \alpha\}]$.) Similarly, if $f : X \to \mathbb{R}$ is upper semi-continuous and $g : Y \to X$ is continuous, then $fg : Y \to \mathbb{R}$ is upper semi-continuous.

(iii) If $f, g : X \to]-\infty, \infty]$ are lower semi-continuous so is $f + g : X \to]-\infty, \infty]$. (Čech 66, 18D.8.)

(iv) If $f, g : X \to [0, \infty]$ are lower semi-continuous so is $f \times g : X \to [0, \infty]$. (Čech 66, 18D.8.)

(v) If Φ is any non-empty set of lower semi-continuous functions from X to $[-\infty, \infty]$, then $x \mapsto \sup_{f \in \Phi} f(x) : X \to [-\infty, \infty]$ is lower semi-continuous.

(vi) $f : X \to \mathbb{R}$ is continuous iff f is both upper semi-continuous and lower semi-continuous iff f and $-f$ are both lower semi-continuous.

(e) Separable spaces (i) If $\langle A_i \rangle_{i \in I}$ is a countable family of separable subsets of a topological space X then $\overline{\bigcup_{i \in I} A_i}$ is separable. (If $D_i \subseteq A_i$ is countable and dense for each i, $\bigcup_{i \in I} D_i$ is countable and dense in $\bigcup_{i \in I} A_i$.)

(ii) If $\langle X_i \rangle_{i \in I}$ is a family of separable topological spaces and $\#(I) \leq \mathfrak{c}$, then $\prod_{i \in I} X_i$ is separable. (Engelking 89, 2.3.16.)

(iii) A continuous image of a separable topological space is separable. (Engelking 89, 1.4.11.)

(f)(i) Let $\langle X_i \rangle_{i \in I}$ be any family of topological spaces, with product X. If $J \subseteq I$ is any set, and we write X_J for $\prod_{i \in J} X_i$, then the canonical map $x \mapsto x{\restriction}J : X \to X_J$ is open. (Engelking 89, p. 79.)

(ii) Let X and Y be topological spaces and $f : X \to Y$ a continuous open map. Then $\operatorname{int} f^{-1}[B] = f^{-1}[\operatorname{int} B]$ and $\overline{f^{-1}[B]} = f^{-1}[\overline{B}]$ for every $B \subseteq Y$. **P** Because f is continuous, $f^{-1}[\operatorname{int} B]$ is an open set included in $f^{-1}[B]$, so is included in $\operatorname{int} f^{-1}[B]$. Because f is open, $f[\operatorname{int} f^{-1}[B]]$ is an open set included in $f[f^{-1}[B]] \subseteq B$, so $f[\operatorname{int} f^{-1}[B]] \subseteq \operatorname{int} B$, that is, $\operatorname{int} f^{-1}[B] \subseteq f^{-1}[\operatorname{int} B]$. Now apply this to $Y \setminus B$ and take complements. **Q**

(g) Let $\langle X_i \rangle_{i \in I}$ be a family of topological spaces with product X.

(i) If $A \subseteq X$ is determined by coordinates in $J \subseteq I$ in the sense of 254M, then $\overline{A}$ and $\operatorname{int} A$ are also determined by coordinates in J. **P** Let $\pi : X \to \prod_{i \in J} X_i$ be the canonical map. Then $A = \pi^{-1}[\pi[A]]$, so (f) tells us that $\operatorname{int} A = \pi^{-1}[\operatorname{int} \pi[A]]$ and $\overline{A} = \pi^{-1}[\overline{\pi[A]}]$; but these are both determined by coordinates in J. **Q**

(ii) If $F \subseteq X$ is closed, there is a smallest set $J^* \subseteq I$ such that F is determined by coordinates in J^*. **P** Let $\mathcal{J}$ be the family of all those sets $J \subseteq I$ such that F is determined by coordinates in $\mathcal{J}$. If J_1, $J_2 \in \mathcal{J}$, then $J_1 \cap J_2 \in \mathcal{J}$ (254Ta). Set $J^* = \bigcap \mathcal{J}$. **?** Suppose, if possible, that F is not determined by coordinates in J^*. Then there are $x \in F$, $y \in X \setminus F$ such that $x{\restriction}J^* = y{\restriction}J^*$. Because $X \setminus F$ is open, there is a finite set $K \subseteq I$ such that $z \notin F$ whenever $z \in X$ and $z{\restriction}K = y{\restriction}K$. Because $\mathcal{J}$ is closed under finite intersections, there is a $J \in \mathcal{J}$ such that $K \cap J = K \cap J^*$. Define $z \in X$ by setting $z(i) = x(i)$ for $i \in J$, $z(i) = y(i)$ for $i \in I \setminus J$. Then $z{\restriction}J = x{\restriction}J$, so $z \in F$, but $z{\restriction}K = y{\restriction}K$, so $z \notin F$. **X**

Thus $J^* \in \mathcal{J}$ and is the required smallest member of $\mathcal{J}$. **Q**

(h) Let X be a topological space.

(i) If $\mathcal{E}$ is a locally finite family of closed subsets of X, then $\bigcup \mathcal{E}'$ is closed for every $\mathcal{E}' \subseteq \mathcal{E}$. (Engelking 89, 1.1.11.)

(ii) If $\langle f_i \rangle_{i \in I}$ is a family in $C(X)$ such that $\langle \{x : f_i(x) \neq 0\} \rangle_{i \in I}$ is locally finite, then we have a continuous function $f : X \to \mathbb{R}$ defined by setting $f(x) = \sum_{i \in I} f_i(x)$ for every $x \in X$. **P** For any x, $\{i : f_i(x) \neq 0\}$ is finite, so f is well-defined. If $x_0 \in X$ and $\epsilon > 0$, there is a neighbourhood V of x_0 such that $J = \{i : i \in I, f_i(x) \neq 0 \text{ for some } x \in V\}$ is finite; now there is a neighbourhood W of x_0, included in V, such that $\sum_{i \in J} |f_i(x) - \sum_{i \in J} f_i(x_0)| < \epsilon$ for every $x \in W$, so that $|f(x) - f(x_0)| < \epsilon$ for every $x \in W$. As x_0 and ϵ are arbitrary, f is continuous. **Q**

(i) Let X be a topological space and A, B two subsets of X. Then $\partial(A * B) \subseteq \partial A \cup \partial B$, where $*$ is any of $\cup$, $\cap$, $\setminus$, $\triangle$. (Generally, if $F \subseteq X$, $\{A : \partial A \subseteq F\} = \{A : \overline{A} \setminus F \subseteq \operatorname{int} A\}$ is a subalgebra of $\mathcal{P}X$.)

4A2C G_δ, F_σ, zero and cozero sets Let X be a topological space.

(a) (i) The union of two G_δ sets in X is a G_δ set. (Engelking 89, p. 26; Kuratowski 66, §5.V.)

(ii) The intersection of countably many G_δ sets is a G_δ set. (Engelking 89, p. 26; Kuratowski 66, §5.V.)

(iii) If Y is another topological space, $f : X \to Y$ is continuous and $E \subseteq Y$ is G_δ in Y, then $f^{-1}[E]$ is G_δ in X. ($f^{-1}[\bigcap_{n\in\mathbb{N}} H_n] = \bigcap_{n\in\mathbb{N}} f^{-1}[H_n]$.)

(iv) If Y is a G_δ set in X and $Z \subseteq Y$ is a G_δ set for the subspace topology of Y, then Z is a G_δ set in X. (Kuratowski 66, §5.V.)

(v) A set $E \subseteq X$ is an F_σ set iff $X \setminus E$ is a G_δ set. (Kuratowski 66, §5.V.)

(b) (i) A zero set is closed. A cozero set is open.

(ii) The union of two zero sets is a zero set. (Császár 78, 4.2.36.) The intersection of two cozero sets is a cozero set.

(iii) The intersection of a sequence of zero sets is a zero set. (If $f_n : X \to \mathbb{R}$ is continuous for each n, $x \mapsto \sum_{n=0}^{\infty} \min(2^{-n}, |f_n(x)|)$ is continuous.) The union of a sequence of cozero sets is a cozero set.

(iv) If Y is another topological space, $f : X \to Y$ is continuous and $L \subseteq Y$ is a zero set, then $f^{-1}[L]$ is a zero set. (Čech 66, 28B.3.) If $f : X \to Y$ is continuous and $L \subseteq Y$ is a cozero set, then $f^{-1}[L]$ is a cozero set. (Čech 66, 28B.3.) If $K \subseteq X$, $L \subseteq Y$ are zero sets then $K \times L$ is a zero set in $X \times Y$. ($K \times L = \pi_1^{-1}[K] \cap \pi_2^{-1}[L]$.)

(v) If $H \subseteq X$ is a (co-)zero set and $Y \subseteq X$, then $H \cap Y$ is a (co-)zero set in Y. (Use (iv).)

(vi) A cozero set is the union of a non-decreasing sequence of zero sets. (If $f : X \to \mathbb{R}$ is continuous, $X \setminus f^{-1}[\{0\}]) = \bigcup_{n\in\mathbb{N}} g_n^{-1}[\{0\}]$, where $g_n(x) = \max(0, 2^{-n} - |f(x)|)$.) In particular, a cozero set is an F_σ set; taking complements, a zero set is a G_δ set.

(vii) If $\mathcal{G}$ is a partition of X into open sets, and $H \subseteq X$ is such that $H \cap G$ is a cozero set in G for every $G \in \mathcal{G}$, then H is a cozero set in X. (If $f_G : G \to \mathbb{R}$ is continuous for every $G \in \mathcal{G}$, then $f : X \to \mathbb{R}$ is continuous, where $f(x) = f_G(x)$ for $x \in G \in \mathcal{G}$.) Similarly, if $F \subseteq X$ is such that $F \cap G$ is a zero set in G for every $G \in \mathcal{G}$, then F is a zero set in X.

4A2D Weight Let X be a topological space.

(a) $w(Y) \leq w(X)$ for every subspace Y of X (4A2B(a-iv)).

(b) A disjoint family $\mathcal{G}$ of non-empty open sets in X has cardinal at most $w(X)$. (If $\mathcal{U}$ is a base for the topology of X, then every non-empty member of $\mathcal{G}$ includes a non-empty member of $\mathcal{U}$, so we have an injective function from $\mathcal{G}$ to $\mathcal{U}$.)

(c) A point-countable family $\mathcal{G}$ of open sets in X has cardinal at most $\max(\omega, w(X))$. **P** If $X = \emptyset$, this is trivial. Otherwise, let $\mathcal{U}$ be a base for the topology of X with $\#(\mathcal{U}) = w(X) > 0$. Choose a function $f : \mathcal{G} \to \mathcal{U}$ such that $\emptyset \neq f(G) \subseteq G$ whenever $G \in \mathcal{G} \setminus \{\emptyset\}$. Then $\mathcal{G}_U = \{G : f(G) = U\}$ is countable for every $U \in \mathcal{U}$, so there is an injection $h_U : \mathcal{G}_U \to \mathbb{N}$; now $G \mapsto (f(G), h_{f(G)}(G)) : \mathcal{G} \to \mathcal{U} \times \mathbb{N}$ is injective, so $\#(\mathcal{G}) \leq \#(\mathcal{U} \times \mathbb{N}) = \max(\omega, w(X))$. **Q**

(d) If X is a dyadic space then X is a continuous image of $\{0,1\}^{w(X)}$. **P** By definition, X is Hausdorff and there are a set I and a continuous surjection $f : \{0,1\}^I \to X$; because any power of $\{0,1\}$ is compact, so is X. If $w(X)$ is finite, $\#(X) = w(X) \leq \#(\{0,1\}^{w(X)})$ and the result is trivial; so we may suppose that $w(X)$ is infinite. Let $\mathcal{U}$ be a base for the topology of X with cardinality $w(X)$. Set $Z = \{0,1\}^I$ and let $\mathcal{E}$ be the algebra of subsets of Z determined by coordinates in finite sets, so that $\mathcal{E}$ is an algebra of subsets of Z and is a base for the topology of Z. For each pair U, V of members of $\mathcal{U}$ such that $\overline{U} \subseteq V$, $f^{-1}[V] \subseteq Z$ is open; the set $\{E : E \in \mathcal{E},\ E \subseteq f^{-1}[V]\}$ is upwards-directed and covers the compact set $f^{-1}[\overline{U}]$, so there is an $E_{UV} \in \mathcal{E}$ such that $f^{-1}[\overline{U}] \subseteq E_{UV} \subseteq f^{-1}[V]$. Let $J \subseteq I$ be a set of cardinal at most $\max(\omega, w(X))$ such that every E_{UV} is determined by coordinates in J. Fix any $w \in \{0,1\}^{I\setminus J}$ and define $g : \{0,1\}^J \to X$ by setting $g(z) = f(z, w)$ for every $z \in \{0,1\}^J$, identifying Z with $\{0,1\}^J \times \{0,1\}^{I\setminus J}$. Then g is continuous. **?** If g is not surjective, set $H = X \setminus g[\{0,1\}^J]$. Take $x \in H$; take $V \in \mathcal{U}$ such that $x \in V \subseteq H$; take an open set G such that $x \in G \subseteq \overline{G} \subseteq V$ (this must be possible because X, being

compact and Hausdorff, is regular); take $U \in \mathcal{U}$ such that $x \in U \subseteq G$, so that $x \in U \subseteq \overline{U} \subseteq V$. Because f is surjective, there is a $(u,v) \in \{0,1\}^J \times \{0,1\}^{I \setminus J}$ such that $f(u,v) = x$. Now $(u,v) \in f^{-1}[U] \subseteq E_{UV}$; as E_{UV} is determined by coordinates in J, $(u,w) \in E_{UV} \subseteq f^{-1}[V]$ and $g(u) = f(u,w) \in V$; but V is supposed to be disjoint from $g[\{0,1\}^J]$. **X** So g is surjective, and X is a continuous image of $\{0,1\}^J$. Since $\#(J) \leq \max(\omega, w(X)) = w(X)$, $\{0,1\}^J$ and X are continuous images of $\{0,1\}^{w(X)}$. **Q**

(e) If X is a dyadic space then X is separable iff it is a continuous image of $\{0,1\}^{\mathfrak{c}}$. **P** $\{0,1\}^{\mathfrak{c}}$ is separable (4A2B(e-ii)), so any continuous image of it is separable. If X is a separable dyadic space, let $A \subseteq X$ be a countable dense set. If G, $G' \subseteq X$ are distinct regular open sets, then $G \cap A \neq G \cap A'$. Thus X has at most $\mathfrak{c}$ regular open sets; since X is compact and Hausdorff, therefore regular, its regular open sets form a base, and $w(X) \leq \mathfrak{c}$. By (d), X is a continuous image of $\{0,1\}^{\max(\omega, w(X))}$ which is in turn a continuous image of $\{0,1\}^{\mathfrak{c}}$. **Q**

4A2E The countable chain condition (a)(i) Let $\langle X_i \rangle_{i \in I}$ be a family of topological spaces. If $X_J = \prod_{i \in J} X_i$ is ccc for every finite $J \subseteq I$, then $X = \prod_{i \in I} X_i$ is ccc. (Kunen 80, II.1.9; Fremlin 84, 12I.)

(ii) A separable topological space is ccc. (If D is a countable dense set and $\mathcal{G}$ is a disjoint family of non-empty open sets, we have a surjection from a subset of D onto $\mathcal{G}$.)

(iii) The product of any family of separable topological spaces is ccc. **P** By 4A2B(e-ii) and (ii) here, the product of finitely many separable spaces is separable, therefore ccc; so we can apply (i). **Q**

(b) Let $\langle X_i \rangle_{i \in I}$ be a family of topological spaces, and suppose that $X = \prod_{i \in I} X_i$ is ccc. For $J \subseteq I$ and $x \in X$ set $X_J = \prod_{i \in J} X_i$, $\pi_J(x) = x \restriction J$.

(i) If $G \subseteq X$ is open, there is an open set $W \subseteq G$ determined by coordinates in a countable subset of I such that $G \subseteq \overline{W}$. **P** Let $\mathcal{W}$ be the family of subsets of X determined by coordinates in countable sets. Then $\mathcal{W}$ is a σ-algebra (254Mb) including the standard base $\mathcal{U}$ for the topology of X. Let $\mathcal{U}_0$ be a maximal disjoint family in $\{U : U \in \mathcal{U}, U \subseteq G\}$. Then $\mathcal{U}_0$ is countable, so $W = \bigcup \mathcal{U}_0$ belongs to $\mathcal{W}$. No member of $\mathcal{U}$ can be included in $G \setminus W$, so $G \setminus \overline{W}$ must be empty, and we have a suitable set. **Q** So $\overline{G}$ and $\operatorname{int} \overline{G}$ are determined by coordinates in a countable set (4A2B(g-ii)); in particular, if G is a regular open set, then it is determined by coordinates in a countable set.

(ii) If $f : X \to \mathbb{R}$ is continuous, there are a countable set $J \subseteq I$ and a continuous function $g : X_J \to \mathbb{R}$ such that $f = g\pi_J$. **P** For each $q \in \mathbb{Q}$, set $F_q = \overline{\{x : f(x) < q\}}$. By (i), F_q is determined by coordinates in a countable set. Because $\mathbb{Q}$ is countable, there is a countable $J \subseteq I$ such that every F_q is determined by coordinates in J. Also $\{x : f(x) < \alpha\} = \bigcup_{q \in \mathbb{Q}, q < \alpha} F_q$ is determined by coordinates in J for every $\alpha \in \mathbb{R}$, so $f(x) = f(y)$ whenever $x \restriction J = y \restriction J$, and there is a $g : X_J \to \mathbb{R}$ such that $f = g\pi_J$. Now if $H \subseteq \mathbb{R}$ is open, $g^{-1}[H] = \pi_J[f^{-1}[H]]$ is open, so g is continuous. **Q**

4A2F Separation axioms (a) Hausdorff spaces (i) A Hausdorff space is T_1. (Čech 66, 27A.1.) Any subspace of a Hausdorff space is Hausdorff. (Engelking 89, 2.1.6; Čech 66, 27A.3; Kuratowski 66, §5.VIII; Császár 78, 2.5.21.)

(ii) If X is a Hausdorff space and $\langle x_n \rangle_{n \in \mathbb{N}}$ is a sequence in X, then a point x of X is a cluster point of $\langle x_n \rangle_{n \in \mathbb{N}}$ iff there is a non-principal ultrafilter $\mathcal{F}$ on $\mathbb{N}$ such that $x = \lim_{n \to \mathcal{F}} x_n$. (If x is a cluster point of $\langle x_n \rangle_{n \in \mathbb{N}}$, apply 4A1Ia to $\{\{n : n \geq n_0, x_n \in G\} : n_0 \in \mathbb{N}, G \subseteq X \text{ is open}, x \in G\}$.)

(b) Regular spaces A regular T_1 space is Hausdorff. (Čech 66, 27B.7; Gaal 64, p. 81.) Any subspace of a regular space is regular. (Engelking 89, 2.1.6; Kuratowski 66, §14.I.)

(c) Completely regular spaces In a completely regular space, the cozero sets form a base for the topology. (Čech 66, 28B.5.)

(d) Normal spaces (i) **Urysohn's Lemma** If X is normal and E, F are disjoint closed subsets of X, then there is a continuous function $f : X \to [0,1]$ such that $f(x) = 0$ for $x \in E$ and $f(x) = 1$ for $x \in F$. (Engelking 89, 1.5.11; Kuratowski 66, §14.IV.)

(ii) A regular normal space is completely regular.

(iii) A normal T_1 space is Hausdorff (Gaal 64, p. 86) and completely regular (Császár 78, 4.2.5; Gaal 64, p. 110).

(iv) If X is normal and E, F are disjoint closed sets in X there is a zero set including E and disjoint from F. (Take a continuous function f which is zero on E and 1 on F, and set $Z = \{x : \max(0, f(x) - \frac{1}{2}) = 0\}$.)

(v) In a normal space a closed G_δ set is a zero set. (Engelking 89, 1.5.12.)

(vi) If X is a normal space and $\langle G_i\rangle_{i\in I}$ is a point-finite cover of X by open sets, there is a family $\langle H_i\rangle_{i\in I}$ of open sets, still covering X, such that $\overline{H}_i \subseteq G_i$ for every i. (Engelking 89, 1.5.18; Čech 66, 29C.1; Gaal 64, p. 89.)

(vii) If X is a normal space and $\langle G_i\rangle_{i\in I}$ is a point-finite cover of X by open sets, there is a family $\langle H'_i\rangle_{i\in I}$ of cozero sets, still covering X, such that $H'_i \subseteq G_i$ for every i. (Take $\langle H_i\rangle_{i\in I}$ from (vi), and apply (iv) to the disjoint closed sets $\overline{H}_i$, $X \setminus G_i$ to find a suitable cozero set H'_i for each i.)

(viii) **Tietze's theorem** Let X be a normal space, F a closed subset of X and $f : F \to \mathbb{R}$ a continuous function. Then there is a continuous function $g : X \to \mathbb{R}$ extending f. (Engelking 89, 2.1.8; Kuratowski 66, §14.IV; Gaal 64, p. 203.) It follows that if $F \subseteq X$ is closed and $f : F \to [0,1]^I$ is a continuous function from F to any power of the unit interval, there is a continuous function from X to $[0,1]^I$ extending f. (Extend each of the functionals $x \mapsto f(x)(i)$ for $i \in I$.)

(ix) If X is a normal space and $\langle G_i\rangle_{i\in I}$ is a locally finite cover of X by open sets, there is a family $\langle g_i\rangle_{i\in I}$ of continuous functions from X to $[0,1]$ such that $g_i \leq \chi G_i$ for every $i \in I$ and $\sum_{i\in I} g_i(x) = 1$ for every $x \in X$. (Engelking 89, proof of 5.1.9.)

(e) Paracompact spaces A Hausdorff paracompact space is regular. (Engelking 89, 5.1.5.) A regular paracompact space is normal. (Engelking 89, 5.1.5; Gaal 64, p. 160.)

(f) Countably paracompact spaces A normal space X is countably paracompact iff whenever $\langle F_n\rangle_{n\in\mathbb{N}}$ is a sequence of closed subsets of X with empty intersection, there is a sequence $\langle G_n\rangle_{n\in\mathbb{N}}$ of open sets, also with empty intersection, such that $F_n \subseteq G_n$ for every $n \in \mathbb{N}$. (Engelking 89, 5.2.2; Császár 78, 8.3.56(f).)

(g) Metacompact spaces (i) A paracompact space is metacompact.

(ii) A closed subspace of a metacompact space is metacompact.

(iii) A normal metacompact space is countably paracompact. (Engelking 89, 5.2.6; Császár 78, 8.3.56(c).)

(h) Separating compact sets (i) If X is a Hausdorff space and K and L are disjoint compact subsets of X, there are disjoint open sets G, $H \subseteq X$ such that $K \subseteq G$ and $L \subseteq H$. (Császár 78, 5.3.18.)

(ii) If X is a regular space, $F \subseteq X$ is closed, and $K \subseteq X \setminus F$ is compact, there are disjoint open sets G, $H \subseteq X$ such that $K \subseteq G$ and $F \subseteq H$. (Engelking 89, 3.1.6.)

(iii) If X is a completely regular space, $G \subseteq X$ is open and $K \subseteq G$ is compact, there is a continuous function $f : X \to [0,1]$ such that $f(x) = 1$ for $x \in K$ and $f(x) = 0$ for $x \in X \setminus G$. **P** For each $x \in K$ there is a continuous function $f_x : X \to [0,1]$ such that $f_x(x) = 1$ and $f_x(y) = 0$ for $y \in X \setminus G$. Set $H_x = \{y : f_x(y) > \frac{1}{2}\}$. Then $\bigcup_{x\in K} H_x \supseteq K$, so there is a finite set $I \subseteq K$ such that $K \subseteq \bigcup_{x\in I} H_x$. Set $f(y) = \min(1, 2\sum_{x\in I} f_x(y))$ for $y \in X$. **Q**

(iv) If X is a completely regular Hausdorff space and K and L are disjoint compact subsets of X, there are disjoint cozero sets G, $H \subseteq X$ such that $K \subseteq G$ and $L \subseteq H$. **P** By (i), there are disjoint open sets G', H' such that $K \subseteq G'$ and $L \subseteq H'$. By (iii), there is a continuous function $f : X \to [0,1]$ such that $f(x) = 1$ for $x \in K$ and $f(x) = 0$ for $x \in X \setminus G'$; set $G = \{x : f(x) \neq 0\}$, so that G is a cozero set and $K \subseteq G \subseteq G'$. Similarly there is a cozero set H including L and included in H'. **Q**

(v) If X is a completely regular space and $K \subseteq X$ is a compact G_δ set, then K is a zero set. **P** Let $\langle G_n\rangle_{n\in\mathbb{N}}$ be a sequence of open sets with intersection K. For each $n \in \mathbb{N}$ there is a continuous function $f_n : X \to [0,1]$ such that $f_n(x) = 1$ for $x \in K$, $f_n(x) = 0$ for $x \in X \setminus G_n$, by (iii). Now $K = \bigcap_{n\in\mathbb{N}}\{x : 1 - f_n(x) = 0\}$ is a zero set, by 4A2C(b-iii). **Q**

(vi) If $\langle X_n\rangle_{n\in\mathbb{N}}$ is a sequence of topological spaces with product X, $K \subseteq X$ is compact, $F \subseteq X$ is closed and $K \cap F = \emptyset$, there is some $n \in \mathbb{N}$ such that $x{\restriction}n \neq y{\restriction}n$ for any $x \in F$, $y \in K$. **P?** Otherwise, we can find for each $n \in \mathbb{N}$ points $x_n \in F$, $y_n \in K$ such that $x_n{\restriction}n = y_n{\restriction}n$. Let $y \in K$ be a cluster point of $\langle y_n\rangle_{n\in\mathbb{N}}$ (2A3Ob). Then $y \notin F$, so there must be an $m \in \mathbb{N}$ and open sets $G_i \subseteq X_i$, for $i \leq m$, such that $y \in G \subseteq X \setminus F$, where $G = \{z : z \in X, z(i) \in G_i \text{ for every } i \leq m\}$. Now there is an $n > m$ such that $y_n \in G$; but in this case $x_n \in G$ and $x_n \notin F$, which is impossible. **XQ**

(vii) If X is a compact Hausdorff space, $f : X \to \mathbb{R}$ is continuous, and $\mathcal{U}$ is a subbase for $\mathfrak{T}$, then there is a countable set $\mathcal{U}_0 \subseteq \mathcal{U}$ such that $f(x) = f(y)$ whenever $\{U : x \in U \in \mathcal{U}\} = \{U : y \in U \in \mathcal{U}\}$. (Apply (i) to sets of the form $K = \{x : f(x) \leq \alpha\}$, $L = \{x : f(x) \geq \beta\}$.)

(i) Perfectly normal spaces A topological space X is perfectly normal iff every closed set is a zero set. (Engelking 89, 1.4.9.)

Consequently, every open set in a perfectly normal space is a cozero set (and, of course, an F_σ set).

4A2G Compact and locally compact spaces (a) In any topological space, the union of two compact subsets is compact.

(b) A compact Hausdorff space is normal. (Engelking 89, 3.1.9; Császár 78, 5.3.23; Gaal 64, p. 139.)

(c) If X is a compact Hausdorff space, $Y \subseteq X$ is a zero set and $Z \subseteq Y$ is a zero set in Y, then Z is a zero set in X. (By 4A2C(b-vi) and 4A2C(a-iv), Z is a G_δ set in X; now use 4A2F(d-v).)

(d) If X is a Hausdorff space, $\mathcal{V}$ is a downwards-directed family of compact neighbourhoods of a point x of X and $\bigcap \mathcal{V} = \{x\}$, then $\mathcal{V}$ is a base of neighbourhoods of $\{x\}$. **P** Let G be any open set containing x. Fix any $V_0 \in \mathcal{V}$. Note that because X is Hausdorff, every member of $\mathcal{V}$ is closed (3A3Dc). So $\{V_0 \cap V \setminus G : V \in \mathcal{V}\}$ is a family of (relatively) closed subsets of V_0 with empty intersection, cannot have the finite intersection property (3A3Da), and there is a $V \in \mathcal{V}$ such that $V_0 \cap V \setminus G = \emptyset$. Now there is a $V' \in \mathcal{V}$ such that $V' \subseteq V_0 \cap V$ and $V' \subseteq G$. As G is arbitrary, $\mathcal{V}$ is a base of neighbourhoods of x. **Q**

(e) Let $(X, \mathfrak{T})$ be a locally compact Hausdorff space.

(i) If $K \subseteq X$ is a compact set and $G \supseteq K$ is open, then there is a continuous $f : X \to [0, 1]$ with compact support such that $\chi K \leq f \leq \chi G$. (Let $\mathcal{V}$ be the family of relatively compact open subsets of X. Then $\mathcal{V}$ is upwards-directed and covers X, so there is a $V \in \mathcal{V}$ including K. By 3A3Bb, $\mathfrak{T}$ is completely regular; now 4A2F(h-iii) tells us that there is a continuous $f : X \to [0, 1]$ such that $\chi K \leq f \leq \chi(G \cap V)$, so that f has compact support.)

(ii) $\mathfrak{T}$ is the coarsest topology on X such that every $\mathfrak{T}$-continuous real-valued function with compact support is continuous. **P** Let Φ be the set of continuous functions of compact support for $\mathfrak{T}$. If $\mathfrak{S}$ is a topology on X such that every member of Φ is continuous, and $x \in G \in \mathfrak{T}$, then there is an $f \in \Phi$ such that $f(x) = 1$ and $f(y) = 0$ for $y \in X \setminus G$, by (i). Now f is $\mathfrak{S}$-continuous, by hypothesis, so $H = \{y : f(y) > \frac{1}{2}\}$ belongs to $\mathfrak{S}$ and $x \in H \subseteq G$. As x is arbitrary, $G = \mathrm{int}_{\mathfrak{S}} G$ belongs to $\mathfrak{S}$; as G is arbitrary, $\mathfrak{T} \subseteq \mathfrak{S}$. **Q**

(f) (i) A topological space X is countably compact iff every sequence in X has a cluster point in X, that is, X is relatively countably compact in itself. (Engelking 89, 3.10.3; Császár 78, 5.3.31(e); Gaal 64, p. 129.)

(ii) If X is a countably compact topological space and $\langle F_n \rangle_{n \in \mathbb{N}}$ is a sequence of closed sets such that $\bigcap_{i \leq n} F_i \neq \emptyset$ for every $n \in \mathbb{N}$, then $\bigcap_{n \in \mathbb{N}} F_n \neq \emptyset$. (Engelking 89, 3.10.3; Császár 78, 5.3.31(c).)

(iii) In any topological space, a relatively compact set is relatively countably compact (2A3Ob).

(iv) Let X and Y be topological spaces and $f : X \to Y$ a continuous function. If $A \subseteq X$ is relatively countably compact in X, then $f[A]$ is relatively countably compact in Y. **P** Let $\langle y_n \rangle_{n \in \mathbb{N}}$ be a sequence in $f[A]$. Then there is a sequence $\langle x_n \rangle_{n \in \mathbb{N}}$ in A such that $f(x_n) = y_n$ for every $n \in \mathbb{N}$. Because A is relatively countably compact, $\langle x_n \rangle_{n \in \mathbb{N}}$ has a cluster point $x \in X$. If $n_0 \in \mathbb{N}$ and H is an open set containing $f(x)$, there is an $n \geq n_0$ such that $x_n \in f^{-1}[H]$, so that $y_n \in H$. Thus $f(x)$ is a cluster point of $\langle y_n \rangle_{n \in \mathbb{N}}$; as $\langle y_n \rangle_{n \in \mathbb{N}}$ is arbitrary, $f[A]$ is relatively countably compact. **Q**

(v) A relatively countably compact set in $\mathbb{R}$ must be bounded. (If $A \subseteq \mathbb{R}$ is unbounded there is a sequence $\langle x_n \rangle_{n \in \mathbb{N}}$ in A such that $|x_n| \geq n$ for every n.) So if X is a topological space, $A \subseteq X$ is relatively countably compact and $f : X \to \mathbb{R}$ is continuous, then $f[A]$ is bounded.

(vi) If X and Y are topological spaces and $f : X \to Y$ is continuous, then $f[A]$ is countably compact whenever $A \subseteq X$ is countably compact. (Engelking 89, 3.10.5.)

(g) (i) Let X and Y be topological spaces and $\phi : X \times Y \to \mathbb{R}$ a continuous function. Define $\theta : X \to C(Y)$ by setting $\theta(x)(y) = \phi(x, y)$ for $x \in X$, $y \in Y$. Then θ is continuous if we give $C(Y)$ the topology of uniform

convergence on compact subsets of Y. (As noted in ENGELKING 89, pp. 157-158, the topology of uniform convergence on compact sets is the 'compact-open' topology of $C(Y)$, so the result here is covered by ENGELKING 89, 3.4.1.)

(ii) In particular, if Y is compact then θ is continuous if we give $C(Y)$ its usual norm topology.

(h) (i) Suppose that X is a compact space such that there are no non-trivial convergent sequences in X, that is, no convergent sequences which are not eventually constant. If $\langle F_n\rangle_{n\in\mathbb{N}}$ is a non-increasing sequence of infinite closed subsets of X, then $F=\bigcap_{n\in\mathbb{N}}F_n$ is infinite. **P** Because X is compact, F cannot be empty (3A3Da). Choose a sequence $\langle x_n\rangle_{n\in\mathbb{N}}$ such that $x_n\in F_n\setminus\{x_i:i<n\}$ for each $n\in\mathbb{N}$. If $G\supseteq F$ is an open set, then $\bigcap_{n\in\mathbb{N}}F_n\setminus G=\emptyset$, so there must be some $n\in\mathbb{N}$ such that $F_n\subseteq G$, and $x_i\in G$ for $i\geq n$. **?** If $F=\{y_0,\dots,y_k\}$, let $l\leq k$ be the first point such that whenever $G\supseteq\{y_0,\dots,y_l\}$ is open, then $\{i:x_i\notin G\}$ is finite. Then there is an open set $G'\supseteq\{y_j:j<l\}$ such that $I=\{i:x_i\notin G'\}$ is infinite. But if H is any open set containing y_l, then $\{i:x_i\notin G'\cup H\}$ is finite, so $\{i:i\in I,\,x_i\notin H\}$ is finite. Thus if we re-enumerate $\langle x_i\rangle_{i\in I}$ as $\langle x'_n\rangle_{n\in\mathbb{N}}$, $\langle x'_n\rangle_{n\in\mathbb{N}}$ converges to y_l and is a non-trivial convergent sequence. **X** Thus F is infinite, as claimed. **Q**

(ii) If X is an infinite scattered compact Hausdorff space it has a non-trivial convergent sequence. **P** Let $\langle x_n\rangle_{n\in\mathbb{N}}$ be any sequence of distinct points in X. Set $F_n=\overline{\{x_i:i\geq n\}}$ for each n, so that $F=\bigcap_{n\in\mathbb{N}}F_n$ is a non-empty set. Because X is scattered, F has an isolated point z say; let G be an open set such that $F\cap G=\{z\}$, and H an open set such that $z\in H\subseteq\overline{H}\subseteq G$ (3A3Bc). In this case, $I=\{i:x_i\in H\}$ must be infinite; re-enumerate $\langle x_i\rangle_{i\in I}$ as $\langle x'_n\rangle_{n\in\mathbb{N}}$. **?** If $\langle x'_n\rangle_{n\in\mathbb{N}}$ does not converge to z, there is an open set H' containing z such that $\{n:x'_n\notin H'\}$ is infinite, that is, $\{i:i\in I,\,x_i\notin H'\}$ is infinite. In this case, $F_n\cap\overline{H}\setminus H'$ is non-empty for every $n\in\mathbb{N}$, but $F\cap\overline{H}\setminus H'=\emptyset$, which is impossible. **X** Thus $\langle x'_n\rangle_{n\in\mathbb{N}}$ is a non-trivial convergent sequence in X. **Q**

(iii) If X is an extremally disconnected Hausdorff space (definition: 3A3Ae), it has no non-trivial convergent sequence. **P?** Suppose, if possible, that there is a sequence $\langle x_n\rangle_{n\in\mathbb{N}}$ converging to $x\in X$ such that $\{n:x_n\neq x\}$ is infinite. Choose $\langle n_i\rangle_{i\in\mathbb{N}}$ and $\langle G_i\rangle_{i\in\mathbb{N}}$ inductively, as follows. Given that $x\notin\overline{G}_j$ for $j<i$, there is an n_i such that $x_{n_i}\neq x$ and $x_{n_i}\notin\overline{G}_j$ for every $j<i$; now let G_i be an open set such that $x_{n_i}\in G_i$ and $x\notin\overline{G}_i$, and continue.

Since all the n_i must be distinct, $\langle x_{n_i}\rangle_{i\in\mathbb{N}}\to x$. But consider

$$G=\bigcup_{i\in\mathbb{N}}G_{2i}\setminus\bigcup_{j<2i}\overline{G}_j,\quad H=\bigcup_{i\in\mathbb{N}}G_{2i+1}\setminus\bigcup_{j\leq 2i}\overline{G}_j.$$

Then G and H are disjoint open sets and $x_{n_{2i}}\in G$, $x_{n_{2i+1}}\in H$ for every i. So $x\in\overline{G}\cap\overline{H}$. But $\overline{G}$ is open (because X is extremally disconnected), and is disjoint from H, and now $\overline{H}$ is disjoint from $\overline{G}$; so they cannot both contain x. **XQ**

(i) (i) Let X be a non-empty compact Hausdorff space without isolated points. Then there are a closed set $F\subseteq X$ and a continuous surjection $f:F\to\{0,1\}^{\mathbb{N}}$. **P** For $\sigma\in\bigcup_{n\in\mathbb{N}}\{0,1\}^n$ choose closed sets $V_\sigma\subseteq X$ inductively, as follows. $V_\emptyset=X$. Given that V_σ is a closed set with non-empty interior, there are distinct points x, $y\in\operatorname{int}V_\sigma$ (because X has no isolated points); let G, H be disjoint open subsets of X such that $x\in G$ and $y\in H$; and let $V_{\sigma^\frown 0}$, $V_{\sigma^\frown 1}$ be closed sets such that

$$x\in\operatorname{int}V_{\sigma^\frown 0}\subseteq G\cap\operatorname{int}V_\sigma,\quad y\in\operatorname{int}V_{\sigma^\frown 1}\subseteq H\cap\operatorname{int}V_\sigma.$$

(This is possible because X is regular.) The construction ensures that $V_\tau\subseteq V_\sigma$ whenever $\tau\in\{0,1\}^n$ extends $\sigma\in\{0,1\}^m$, and that $V_\tau\cap V_\sigma=\emptyset$ whenever τ, $\sigma\in\{0,1\}^n$ are different. Set $F=\bigcap_{n\in\mathbb{N}}\bigcup_{\sigma\in\{0,1\}^n}V_\sigma$; then F is a closed subset of X and we have a continuous function $f:F\to\{0,1\}^{\mathbb{N}}$ defined by saying that $f(x)(i)=\sigma(i)$ whenever $n\in\mathbb{N}$, $\sigma\in\{0,1\}^n$, $i<n$ and $x\in V_\sigma$. Finally, f is surjective, because if $z\in\{0,1\}^{\mathbb{N}}$ then $\langle V_{z\restriction n}\rangle_{n\in\mathbb{N}}$ is a non-increasing sequence of closed sets in the compact space X, so has non-empty intersection V say, and $f(x)=z$ for any $x\in V$. **Q**

(ii) If X is a non-empty compact Hausdorff space without isolated points, then $\#(X)\geq\mathfrak{c}$. (Use (i).)

(iii) If X is a compact Hausdorff space which is not scattered, it has an infinite closed subset without isolated points with a countable π-base. **P** Because X is not scattered, it has a non-empty subset A without isolated points. Then $\overline{A}$ is compact and has no isolated points; by (i), there are a closed set $F_0\subseteq\overline{A}$ and a continuous surjection $f:F_0\to\{0,1\}^{\mathbb{N}}$. Let $\mathcal{F}$ be the family of closed sets $F\subseteq F_0$ such that $f[F]=\{0,1\}^{\mathbb{N}}$. If $\mathcal{F}'\subseteq\mathcal{F}$ is non-empty and downwards-directed, then $F'=\bigcap\mathcal{F}'$ is closed; also, for every $z\in\{0,1\}^{\mathbb{N}}$,

$\{F \cap f^{-1}[\{z\}] : F \in \mathcal{F}'\}$ is a downwards-directed family of closed sets in the compact space X, so has non-empty intersection, and $F' \cap f^{-1}[\{z\}] \neq \emptyset$; as z is arbitrary, $f[F'] = \{0,1\}^{\mathbb{N}}$, and $F' \in \mathcal{F}$. Thus every totally ordered subset of $\mathcal{F}$ has a lower bound in $\mathcal{F}$, and $\mathcal{F}$ has a minimal element F_1 say.

Let $\mathcal{U}$ be a countable base for the topology of $\{0,1\}^{\mathbb{N}}$, and set $\mathcal{V} = \{F_1 \cap f^{-1}[U] : U \in \mathcal{U}\}$, so that $\mathcal{V}$ is a countable family of relatively open subsets of F_1. If $H \subseteq F_1$ is relatively open and not empty, then $F_1 \setminus H$ is a proper closed subset of F_1; because F_1 is minimal in $\mathcal{F}$, $F_1 \setminus H \notin \mathcal{F}$ and $f[F_1 \setminus H] \neq \{0,1\}^{\mathbb{N}}$. But $F_1 \setminus H$ is compact, so $f[F_1 \setminus H]$ is compact and its complement in $\{0,1\}^{\mathbb{N}}$ is open; there is therefore a non-empty $U \in \mathcal{U}$ such that $U \cap f[F_1 \setminus H] = \emptyset$ and $f^{-1}[U] \cap F_1 \subseteq H$. But as $f[F_1] = \{0,1\}^{\mathbb{N}}$, $f^{-1}[U] \cap F_1$ is not empty, and is a non-empty member of $\mathcal{V}$ included in H. As H is arbitrary, $\mathcal{V}$ is a π-base for the topology of F_1, and F_1 is a closed subset of X with a countable π-base. **Q**

(iv) Let X be a compact Hausdorff space. Then there is a continuous surjection from X onto $[0,1]$ iff X is not scattered. **P** (α) Suppose that $f : X \to [0,1]$ is a continuous surjection. Let $\mathcal{E}$ be the family of closed sets $F \subseteq X$ such that $f[F] = [0,1]$. If $\mathcal{F} \subseteq \mathcal{E}$ is non-empty and downwards-directed, then for any $t \in [0,1]$ the family $\{F \cap f^{-1}[\{t\}] : F \in \mathcal{F}\}$ is a downwards-directed family of non-empty closed sets, so (because X is compact) has non-empty intersection; this shows that $\bigcap \mathcal{F} \in \mathcal{E}$. By Zorn's Lemma, $\mathcal{E}$ has a minimal element K say. **?** If $x \in K$ is an isolated point of K, then $K \setminus \{x\}$ is closed, therefore compact, and $f[K \setminus \{x\}] \supseteq [0,1] \setminus \{f(x)\}$ is compact and dense in $[0,1]$. But this means that $K \setminus \{x\} \in \mathcal{E}$ and K is not minimal. **X** Thus $K \subseteq X$ is a non-empty set with no isolated points and X is not scattered. (β) If X is not scattered, let $A \subseteq X$ be a non-empty set with no isolated points. Then $\overline{A}$ is a non-empty compact subset of X with no isolated points, so there is a continuous surjection $g : \overline{A} \to \{0,1\}^{\mathbb{N}}$ ((i) above). Now there is a continuous surjection $h : \{0,1\}^{\mathbb{N}} \to [0,1]$ (e.g., set $h(y) = \sum_{n=0}^{\infty} 2^{-n-1} y(n)$ for $y \in \{0,1\}^{\mathbb{N}}$), so we have a continuous surjection $hg : \overline{A} \to [0,1]$. By Tietze's theorem (4A2F(d-viii)), there is a continuous function $f_0 : X \to \mathbb{R}$ extending hg; setting $f(x) = \max(0, \min(f_0(x), 1))$ for $x \in X$, we have a continuous surjection $f : X \to [0,1]$. **Q**

(v) A Hausdorff continuous image of a scattered compact Hausdorff space is scattered. (Immediate from (iv).)

(vi) If X is an uncountable first-countable compact Hausdorff space, it is not scattered. **P** Let $\mathcal{G}$ be the family of countable open subsets of X, and G^* its union. No finite subset of $\mathcal{G}$ can cover X, so $X \setminus G^*$ is non-empty. **?** If x is an isolated point of $X \setminus G^*$, then $\{x\} \cup G^*$ is a neighbourhood of x; let $\langle U_n \rangle_{n \in \mathbb{N}}$ run over a base of open neighbourhoods of x with $\overline{U}_0 \subseteq \{x\} \cup G^*$. For each $n \in \mathbb{N}$, $F_n = \overline{U}_0 \setminus U_n$ is a compact set included in G^*, so is covered by finitely many members of $\mathcal{G}$, and is countable. But this means that $U_0 = \{x\} \cup \bigcup_{n \in \mathbb{N}} U_0 \setminus U_n$ is countable, and $x \in G^*$. **X** Thus $X \setminus G^*$ is a non-empty set with no isolated points, and X is not scattered. **Q**

It follows that there is a continuous surjection from X onto $[0,1]$, by (iv).

(j) A locally compact Hausdorff space is Čech-complete. (Engelking 89, p. 196.)

(k) If X is a topological space, $f : X \to \mathbb{R}$ is lower semi-continuous, and $K \subseteq X$ is compact and not empty, then there is an $x_0 \in K$ such that $f(x_0) = \inf_{x \in K} f(x)$. Similarly, if $g : X \to \mathbb{R}$ is upper semi-continuous, there is an $x_1 \in K$ such that $g(x_1) = \sup_{x \in K} g(x)$.

4A2H Lindelöf spaces (a) If X is a topological space, then a subset Y of X is Lindelöf (in its subspace topology) iff for every family $\mathcal{G}$ of open subsets of X covering Y there is a countable subfamily of $\mathcal{G}$ still covering Y.

(b) (i) A regular Lindelöf space X is paracompact, therefore normal and completely regular. (Engelking 89, 3.8.11 & 5.1.2.)

(ii) If X is a Lindelöf space and $\mathcal{A}$ is a locally finite family of subsets of X then $\mathcal{A}$ is countable. **P** The family $\mathcal{G}$ of open sets meeting only finitely many members of $\mathcal{A}$ is an open cover of X. If $\mathcal{G}_0 \subseteq \mathcal{G}$ is a countable cover of X then $\{A : A \in \mathcal{A}, A \text{ meets some member of } \mathcal{G}_0\} = \mathcal{A} \setminus \{\emptyset\}$ is countable. **Q**

(c) (i) A topological space X is hereditarily Lindelöf iff for any family $\mathcal{G}$ of open subsets of X there is a countable family $\mathcal{G}_0 \subseteq \mathcal{G}$ such that $\bigcup \mathcal{G}_0 = \bigcup \mathcal{G}$. **P** ($\alpha$) If X is hereditarily Lindelöf and $\mathcal{G}$ is a family of open subsets of X, then $\mathcal{G}$ is an open cover of $\bigcup \mathcal{G}$, so has a countable subcover. (β) If X is not hereditarily Lindelöf, let $Y \subseteq X$ be a non-Lindelöf subspace, and $\mathcal{H}$ a cover of Y by relatively open sets which has no

countable subcover; setting $\mathcal{G} = \{G : G \subseteq X \text{ is open}, G \cap Y \in \mathcal{H}\}$, there can be no countable $\mathcal{G}_0 \subseteq \mathcal{G}$ with union $\bigcup \mathcal{G}$. **Q**

(ii) Let X be a regular hereditarily Lindelöf space. Then every closed subset of X is a zero set, so X is perfectly normal. **P** Let $F \subseteq X$ be closed. Let $\mathcal{G}$ be the family of open sets $G \subseteq X$ such that $\overline{G} \cap F = \emptyset$; because X is regular, $\bigcup \mathcal{G} = X \setminus F$; because X is hereditarily Lindelöf, there is a sequence $\langle G_n \rangle_{n \in \mathbb{N}}$ in G such that $X \setminus F = \bigcup_{n \in \mathbb{N}} G_n$. This means that $F = \bigcap_{n \in \mathbb{N}} X \setminus \overline{G_n}$ is a G_δ set. But X is normal ((b) above), so F is a zero set (4A2F(d-v)). By 4A2Fi, X is perfectly normal. **Q**

(d) Any σ-compact topological space is Lindelöf. (Engelking 89, 3.8.5.)

4A2I Stone-Čech compactifications (a) Let X be a completely regular Hausdorff space. Then there is a compact Hausdorff space βX, the **Stone-Čech compactification** of X, in which X can be embedded as a dense subspace. If Y is another compact Hausdorff space, then every continuous function from X to Y has a unique continuous extension to a continuous function from βX to Y. (Engelking 89, 3.6.1; Császár 78, 6.4d; Čech 66, 41D.5.)

(b) Let I be any set, and write βI for its Stone-Čech compactification when I is given its discrete topology.

(i) Let Z be the Stone space of the Boolean algebra $\mathcal{P}I$. Then there is a canonical homeomorphism $\phi : \beta I \to Z$ defined by saying that $\phi(i)(a) = \chi a(i)$ for every $i \in I$, $a \subseteq Z$. **P** Recall that Z is the set of ring homomorphisms from $\mathcal{P}I$ onto $\mathbb{Z}_2$ (311E). If $i \in I$, let $\hat{i}$ be the corresponding member of Z defined by setting $\hat{i}(a) = \chi a(i)$ for every $a \subseteq I$. Then $i \mapsto \hat{i} : I \to Z$ is continuous, while Z is compact and Hausdorff (311I), so has a unique extension to a continuous function $\phi : \beta I \to Z$.

If $G \subseteq Z$ is open and not empty, it includes a set of the form $\widehat{a} = \{\theta : \theta \in Z, \theta(a) = 1\}$ where $a \subseteq I$ is not empty; if i is any member of a, $\hat{i} \in G$ so $G \cap \phi[\beta I] \neq \emptyset$. This shows that $\phi[\beta I]$ is dense in Z; as βI is compact, $\phi[\beta I]$ is compact, therefore closed, and is equal to Z. Thus ϕ is surjective.

If t, u are distinct points of βI, there is an open subset H of βI such that $t \in H$ and $u \notin \overline{H}$. Set $a = H \cap I$. Then $t \in \overline{a}$, the closure of a regarded as a subset of βI, so $\phi(t) \in \overline{\phi[a]}$ (3A3Cd). But $\phi[a] = \{\hat{i} : i \in a\} \subseteq \widehat{a}$, which is open-and-closed, so $\phi(t) \in \widehat{a}$. Similarly, setting $b = I \setminus \overline{H}$, $\phi(u) \in \widehat{b}$; since $\widehat{a} \cap \widehat{b} = \widehat{a \cap b}$ is empty, $\phi(t) \neq \phi(u)$. This shows that ϕ is injective, therefore a homeomorphism between βI and Z (3A3Dd). **Q**

(ii) $C(\beta I)$ is isomorphic, as Banach lattice, to $\ell^\infty(I)$. **P** Let Z be the Stone space of $\mathcal{P}I$. By 363Ha, we can identify $\ell^\infty(I)$, as Banach lattice, with $L^\infty(\mathcal{P}I) = C(Z)$. But (i) tells us that we have a canonical identification between $C(Z)$ and $C(\beta I)$. **Q**

(iii) We have a one-to-one correspondence between filters $\mathcal{F}$ on I and non-empty closed sets $F \subseteq \beta I$, got by matching $\mathcal{F}$ with $\bigcap\{\widehat{a} : a \in \mathcal{F}\}$, or F with $\{a : a \subseteq I, F \subseteq \widehat{a}\}$, where $\widehat{a} \subseteq \beta I$ is the open-and-closed set corresponding to $a \subseteq I$. **P** The identification of βI with the Stone space Z of $\mathcal{P}I$ ((i) above) means that we can regard the map $a \mapsto \widehat{a}$ as a Boolean isomorphism between $\mathcal{P}I$ and the algebra of open-and-closed subsets of βI (311I). For any filter $\mathcal{F}$ on I, set $H(\mathcal{F}) = \bigcap\{\widehat{a} : a \in \mathcal{F}\}$; because $\{\widehat{a} : a \in \mathcal{F}\}$ is a downwards-directed family of non-empty closed sets in the compact Hausdorff space βI, $H(\mathcal{F})$ is a non-empty closed set. If $F \subseteq \beta I$ is a non-empty closed set, then it is elementary to check that $\mathcal{H}(F) = \{a : F \subseteq \widehat{a}\}$ is a filter on I, and evidently $H(\mathcal{H}(F)) \supseteq F$. But if $t \in \beta I \setminus F$, then (because $\{\widehat{a} : a \subseteq I\}$ is a base for the topology of βI, see 311I again) there is an $a \subseteq I$ such that $t \in \widehat{a}$ and $F \cap \widehat{a} = \emptyset$, that is, $F \subseteq \widehat{I \setminus a}$; so $\widehat{I \setminus a} \in \mathcal{H}(F)$ and $H(\mathcal{H}(F)) \subseteq \widehat{I \setminus a}$ and $t \notin H(\mathcal{H}(F))$. Thus $H(\mathcal{H}(F)) = F$ for every non-empty closed set $F \subseteq \beta I$.

If $\mathcal{F}_1$ and $\mathcal{F}_2$ are filters on I and $a \in \mathcal{F}_1 \setminus \mathcal{F}_2$, then $\{\widehat{b \setminus a} : b \in \mathcal{F}_2\}$ is a downwards-directed family of non-empty closed sets in βI, so has non-empty intersection; if $t \in \widehat{b \setminus a} = \widehat{b} \setminus \widehat{a}$ for every $b \in \mathcal{F}_2$, then $t \in H(\mathcal{F}_2) \setminus H(\mathcal{F}_1)$. This shows that $\mathcal{F} \mapsto H(\mathcal{F})$ is injective. It follows that $\mathcal{F} \mapsto H(\mathcal{F})$, $F \mapsto \mathcal{H}(F)$ are the two halves of a bijection, as claimed. **Q**

(iv) There are no non-trivial convergent sequences in βI. **P** Because $\mathcal{P}I$ is Dedekind complete, its Stone space is extremally disconnected (314S), so, by the identification in (i), βI is extremally disconnected, and has no non-trivial convergent sequences (4A2G(h-iii)). **Q** (Compare Engelking 89, 3.6.15.)

4A2J Uniform spaces (See §3A4.) Let $(X, \mathcal{W})$ be a uniform space; give X the associated topology $\mathfrak{T}$ (3A4Ab).

(a) $\mathcal{W}$ is generated by a family of pseudometrics. (Engelking 89, 8.1.11; Bourbaki 66, IX.1.4; Császár 78, 4.2.32.) More precisely: if $\langle W_n\rangle_{n\in\mathbb{N}}$ is any sequence in $\mathcal{W}$, there is a pseudometric ρ on X such that (α) $\{(x,y) : \rho(x,y) \leq \epsilon\} \in \mathcal{W}$ for every $\epsilon > 0$ (β) whenever $n \in \mathbb{N}$ and $\rho(x,y) < 2^{-n}$ then $(x,y) \in W_n$ (Engelking 89, 8.1.10).

It follows that $\mathfrak{T}$ is completely regular, therefore regular (3A3Be). $\mathfrak{T}$ is defined by the bounded uniformly continuous functions, in the sense that it is the coarsest topology $\mathfrak{S}$ on X such that these are all continuous. **P** Let P be the family of pseudometrics compatible with $\mathcal{W}$ in the sense of (α) just above. If $x \in G \in \mathfrak{T}$, there is a $\rho \in$ P such that $\{y : \rho(x,y) < 1\} \subseteq G$; setting $f(y) = \rho(x,y)$, we see that f is uniformly continuous, therefore $\mathfrak{S}$-continuous, and that $x \in \operatorname{int}_{\mathfrak{S}} G$. As x is arbitrary, $G \in \mathfrak{S}$; as G is arbitrary, $\mathfrak{T} \subseteq \mathfrak{S}$; but of course $\mathfrak{S} \subseteq \mathfrak{T}$ just because uniformly continuous functions are continuous. **Q**

(b) If $W \in \mathcal{W}$ and $x \in X$ then $x \in \operatorname{int} W[\{x\}]$. (Engelking 89, 8.1.3.) If $A \subseteq X$ then $\overline{A} = \bigcap_{W\in\mathcal{W}} W[A]$. (Engelking 89, 8.1.4.)

(c) Any subset of a totally bounded set in X is totally bounded. (Engelking 89, 8.3.2; Császár 78, 3.2.70.) The closure of a totally bounded set is totally bounded. **P** If A is totally bounded and $W \in \mathcal{W}$, take $W' \in \mathcal{W}$ such that $W' \circ W' \subseteq W$. Then there is a finite set $I \subseteq X$ such that $A \subseteq W'[I]$. In this case

$$\overline{A} \subseteq W'[A] \subseteq W'[W'[I]] = (W' \circ W')[I] \subseteq W[I]$$

by (b). As W is arbitrary, $\overline{A}$ is totally bounded. **Q**

(d) A subset of X is compact iff it is complete (definition: 3A4F) (for its subspace uniformity) and totally bounded. (Engelking 89, 8.3.16; Čech 66, 41A.8; Császár 78, 5.2.22; Gaal 64, pp. 278-279.) So if X is complete, every closed totally bounded subset of X is compact, and the totally bounded sets are just the relatively compact sets. (A closed subspace of a complete space is complete.)

(e) If $f : X \to \mathbb{R}$ is a continuous function with compact support, it is uniformly continuous. **P** Set $K = \overline{\{x : f(x) \neq 0\}}$. Let $\epsilon > 0$. For each $x \in X$, there is a $W_x \in \mathcal{W}$ such that $|f(y) - f(x)| \leq \frac{1}{2}\epsilon$ whenever $y \in W_x[\{x\}]$. Let $W'_x \in \mathcal{W}$ be such that $W'_x \circ W'_x \subseteq W_x$. Set $G_x = \operatorname{int} W'_x[\{x\}]$; then $x \in G_x$, by (b). Because K is compact, there is a finite set $I \subseteq K$ such that $K \subseteq \bigcup_{x\in I} G_x$. Set $W = (X \times X) \cap \bigcap_{x\in I} W'_x \in \mathcal{W}$. Take any $(y,z) \in W \cap W^{-1}$. If neither y nor z belongs to K, then of course $|f(y) - f(z)| \leq \epsilon$. If $y \in K$, let $x \in I$ be such that $y \in G_x$. Then

$$y \in W'_x[\{x\}] \subseteq W_x[\{x\}], \quad z \in W[W'_x[\{x\}]] \subseteq W'_x[W'_x[\{x\}]] \subseteq W_x[\{x\}],$$

so

$$|f(y) - f(z)| \leq |f(y) - f(x)| + |f(z) - f(x)| \leq \epsilon.$$

The same idea works if $z \in K$. So $|f(y) - f(z)| \leq \epsilon$ for all y, $z \in W \cap W^{-1}$; as ϵ is arbitrary, f is uniformly continuous. **Q**

(f) (i) If $(Y, \mathfrak{S})$ is a completely regular space, there is a uniformity on Y compatible with $\mathfrak{S}$. (Engelking 89, 8.1.20.)

(ii) If $(Y, \mathfrak{S})$ is a compact Hausdorff space, there is exactly one uniformity on Y compatible with $\mathfrak{S}$; it is induced by the set of all those pseudometrics on Y which are continuous as functions from $Y \times Y$ to $\mathbb{R}$. (Engelking 89, 8.3.13.)

(iii) If $(Y, \mathfrak{S})$ is a compact Hausdorff space and $\mathcal{V}$ is the uniformity on Y compatible with $\mathfrak{S}$, then any continuous function from Y to X is uniformly continuous.

(g) The set U of uniformly continuous real-valued functions on X is a Riesz subspace of $\mathbb{R}^X$ containing the constant functions. If a sequence in U converges uniformly, the limit function again belongs to U.

4A2K First-countable, sequential and countably tight spaces (a) Let X be a countably tight topological space. If $\langle F_\xi\rangle_{\xi<\zeta}$ is a non-decreasing family of closed subsets of X indexed by an ordinal ζ, then $E = \bigcup_{\xi<\zeta} F_\xi$ is closed unless $\operatorname{cf}\zeta = \omega$, in which case E is an F_σ set. **P** If $\operatorname{cf}\zeta = 0$, that is, $\zeta = 0$, then $E = \emptyset$ is closed. If $\operatorname{cf}\zeta = 1$, that is, $\zeta = \xi + 1$ for some ordinal ξ, then $E = F_\xi$ is closed. If $\operatorname{cf}\zeta = \omega$, there is a sequence $\langle\xi_n\rangle_{n\in\mathbb{N}}$ in ζ with supremum ζ, so that $E = \bigcup_{n\in\mathbb{N}} F_{\xi_n}$ is F_σ. If $\operatorname{cf}\zeta > \omega$, take $x \in \overline{E}$. Then there is a sequence $\langle x_n\rangle_{n\in\mathbb{N}}$ in E such that $x \in \overline{\{x_n : n \in \mathbb{N}\}}$. For each n there is a $\xi_n < \zeta$ such that $x_n \in F_{\xi_n}$, and now $\xi = \sup_{n\in\mathbb{N}} \xi_n < \zeta$ and $x \in \overline{F}_\xi = F_\xi \subseteq E$. As x is arbitrary, E is closed. **Q**

(b) If X is countably tight, any subspace of X is countably tight, just because if $A \subseteq Y \subseteq X$ then the closure of A in Y is the intersection of Y with the closure of A in X. If X is compact and countably tight, then any Hausdorff continuous image of X is countably tight. **P** Let $f : X \to Y$ be a continuous surjection, where Y is Hausdorff, B a subset of Y and $y \in \overline{B}$. Set $A = f^{-1}[B]$. Then $\overline{A}$ is compact, so $f[\overline{A}]$ is compact, therefore closed; because f is surjective, $y \in \overline{f[A]} \subseteq f[\overline{A}]$, and there is an $x \in \overline{A}$ such that $f(x) = y$. Now there is a countable set $A_0 \subseteq A$ such that $x \in \overline{A}_0$, in which case

$$y = f(x) \in f[\overline{A}_0] \subseteq \overline{f[A_0]},$$

while $f[A_0]$ is a countable subset of B. **Q**

(c) If X is a sequential space, it is countably tight. **P** Suppose that $A \subseteq X$ and $x \in \overline{A}$. Set $B = \bigcup\{\overline{C} : C \subseteq A \text{ is countable}\}$. If $\langle x_n\rangle_{n\in\mathbb{N}}$ is a sequence in B converging to $x \in X$, then for each $n \in \mathbb{N}$ we can find a countable set $C_n \subseteq A$ such that $x_n \in \overline{C}_n$, and now $C = \bigcup_{n\in\mathbb{N}} C_n$ is a countable subset of A such that $x \in \overline{C} \subseteq B$. So B is sequentially closed, therefore closed, and $x \in B$. As A and x are arbitrary, X is countably tight. **Q**

(d) If X is a sequential space, Y is a topological space and $f : X \to Y$ is sequentially continuous, then it is continuous. (Engelking 89, 1.6.15.)

(e) First-countable spaces are sequential. (Engelking 89, 1.6.14.)

(f) Let X be a locally compact Hausdorff space in which every singleton set is G_δ. Then X is first-countable. **P** If $\{x\} = \bigcap_{n\in\mathbb{N}} G_n$ where each G_n is open, then for each $n \in \mathbb{N}$ we can find a compact set F_n such that $x \in \operatorname{int} F_n \subseteq G_n$. By 4A2Gd, $\{\bigcap_{i\le n} F_i : n \in \mathbb{N}\}$ is a base of neighbourhoods of x. **Q**

4A2L (Pseudo-)metrizable spaces 'Pseudometrizable' spaces, as such, hardly appear in this volume, for the usual reasons; they surface briefly in §463. It is perhaps worth noting, however, that all the ideas, and very nearly all the results, in this paragraph apply equally well to pseudometrics and pseudometrizable topologies.

(a) Any subspace of a (pseudo-)metrizable space is (pseudo-)metrizable (2A3J). A topological space is metrizable iff it is pseudometrizable and Hausdorff (2A3L).

(b) Metrizable spaces are paracompact (Engelking 89, 5.1.3; Császár 78, 8.3.16; Čech 66, 30C.2; Gaal 64, p. 155), therefore hereditarily metacompact ((a) above and 4A2F(g-i)).

(c) A metrizable space is perfectly normal (Engelking 89, 4.1.13; Császár 78, 8.4.5.), so every closed set is a zero set and every open set is a cozero set (in particular, is F_σ).

(d) If X is a pseudometrizable space, it is first-countable. (If ρ is a pseudometric defining the topology of X, and x is any point of X, then $\{\{y : \rho(y,x) < 2^{-n}\} : n \in \mathbb{N}\}$ is a base of neighbourhoods of x.) So X is sequential and countably tight (4A2Ke, 4A2Kc), and if Y is another topological space and $f : X \to Y$ is sequentially continuous, then f is continuous (4A2Kd).

(e) Relative compactness Let X be a pseudometrizable space and A a subset of X. Then the following are equiveridical: (α) A is relatively compact; (β) A is relatively countably compact; (γ) every sequence in A has a subsequence with a limit in X. **P** Fix a pseudometric ρ defining the topology of X. (α)⇒(β) by 4A2G(f-iii). If $\langle x_n\rangle_{n\in\mathbb{N}}$ is a sequence in A with a cluster point $x \in X$, then we can choose $\langle n_i\rangle_{i\in\mathbb{N}}$ inductively

such that $\rho(x_{n_i}, x) \leq 2^{-i}$ and $n_{i+1} > n_i$ for every i; now $\langle x_{n_i}\rangle_{i\in\mathbb{N}} \to x$; it follows that $(\beta)\Rightarrow(\gamma)$. Now assume that (α) is false. Then there is an ultrafilter $\mathcal{F}$ on X containing A which has no limit in X (3A3Be, 3A3De). If $\mathcal{F}$ is a Cauchy filter, choose $F_n \in \mathcal{F}$ such that $\rho(x, y) \leq 2^{-n}$ whenever x, $y \in F_n$, and $x_n \in A \cap \bigcap_{i\leq n} F_i$ for each n; then it is easy to see that $\langle x_n\rangle_{n\in\mathbb{N}}$ is a sequence in A with no convergent subsequence. If $\mathcal{F}$ is not a Cauchy filter, let $\epsilon > 0$ be such that there is no $F \in \mathcal{F}$ such that $\rho(x, y) \leq \epsilon$ for every x, $y \in F$. Then $X \setminus U(x, \frac{1}{2}\epsilon) \in \mathcal{F}$ for ever $x \in X$, so we can choose $\langle x_n\rangle_{n\in\mathbb{N}}$ inductively such that $x_n \in A \setminus \bigcup_{i<n} U(x_i, \frac{1}{2}\epsilon)$ for every $n \in \mathbb{N}$, and again we have a sequence $\langle x_n\rangle_{n\in\mathbb{N}}$ in A with no convergent subsequence in X. Thus not-$(\alpha)\Rightarrow$ not-(γ) and the proof is complete. **Q**

(f) Compactness If X is a pseudometrizable space, it is compact iff it is countably compact iff it is sequentially compact. ((e) above, using 4A2G(f-i). Compare Engelking 89, 4.1.17, and Császár 78, 5.3.33 & 5.3.47.)

(g) (i) If (X, ρ) is a metric space, its topology has a base which is σ-metrically-discrete. **P** Enumerate X as $\langle x_\xi\rangle_{\xi<\kappa}$ where κ is a cardinal. Let $\langle(q_n, q'_n)\rangle_{n\in\mathbb{N}}$ be a sequence running over $\{(q, q') : q, q' \in \mathbb{Q}, 0 < q < q'\}$ in such a way that $q'_n - q_n \geq 2^{-n}$ for every $n \in \mathbb{N}$. For $n \in \mathbb{N}$, $\xi < \kappa$ set $G_{n\xi} = \{x : \rho(x, x_\xi) < q_n, \inf_{\eta<\xi} \rho(x, x_\eta) > q'_n\}$ (interpreting $\inf \emptyset$ as ∞). Then $\mathcal{U} = \langle G_{n\xi}\rangle_{\xi<\kappa,n\in\mathbb{N}}$ is a σ-metrically-discrete family of open sets. If $G \subseteq X$ is open and $x \in G$, let $\epsilon > 0$ be such that $U(x, 2\epsilon) \subseteq G$. Let $\xi < \kappa$ be minimal such that $\rho(x, x_\xi) < \epsilon$, and let $n \in \mathbb{N}$ be such that $\rho(x, x_\xi) < q_n < q'_n < \epsilon$; then $x \in G_{n\xi} \subseteq G$. As x and G are arbitrary, $\mathcal{U}$ is a base for the topology of X. **Q**

(ii) Consequently, any metrizable space has a σ-disjoint base. (Compare Engelking 89, 4.4.3; Császár 78, 8.4.5; Kuratowski 66, §21.XVII.)

(h) The product of a countable family of metrizable spaces is metrizable. (Engelking 89, 4.2.2; Császár 78, 7.3.27.)

(i) Let X be a metrizable space and $\kappa \geq \omega$ a cardinal. Then $w(X) \leq \kappa$ iff X has a dense subset of cardinal at most κ. (Engelking 89, 4.1.15.)

(j) If (X, ρ) is any metric space, then the balls $B(x, \delta) = \{y : \rho(y, x) \leq \delta\}$ are all closed sets (cf. 1A2G). In particular, in a normed space $(X, \|\,\|)$, the balls $B(x, \delta) = \{y : \|y - x\| \leq \delta\}$ are closed.

4A2M Complete metric spaces (a) Baire's theorem for complete metric spaces In a complete metric space, the intersection of a sequence of dense G_δ sets is dense. (Engelking 89, 4.3.36 & 3.9.4; Császár 78, 9.2.1 & 9.2.8; Gaal 64, p. 287; Kechris 95, 8.4.) So a non-empty complete metric space is not meager (cf. 3A3Ha).

(b) Let $\langle(X_i, \rho_i)\rangle_{i\in I}$ be a countable family of complete metric spaces. Then there is a complete metric on $X = \prod_{i\in I} X_i$ which defines the product topology on X. (Engelking 89, 4.3.12; Kuratowski 66, §33.III.)

(c) Let (X, ρ) be a complete metric space, and $E \subseteq X$ a G_δ set. Then there is a complete metric on E which defines the subspace topology of E. (Engelking 89, 4.3.23; Kuratowski 66, §33.VI; Kechris 95, 3.11.)

(d) Let (X, ρ) be a complete metric space. Then it is Čech-complete. (Engelking 89, 4.3.26.)

(e) A non-empty complete metric space without isolated points is uncountable. (If x is not isolated $\{x\}$ is nowhere dense.)

4A2N Countable networks: Proposition (a) If X is a topological space with a countable network, any subspace of X has a countable network.

(b) Let X be a space with a countable network. Then X is hereditarily Lindelöf. If it is regular, every closed set is a zero set.

(c) If X is a topological space, and $\langle A_n\rangle_{n\in\mathbb{N}}$ is a sequence of subsets of X each of which has a countable network (for its subspace topology), then $A = \bigcup_{n\in\mathbb{N}} A_n$ has a countable network.

(d) A continuous image of a space with a countable network has a countable network.

(e) Let $\langle X_i\rangle_{i\in I}$ be a countable family of topological spaces with countable networks, with product X. Then X has a countable network.

(f) If X is a Hausdorff space with a countable network, there is a countable family $\mathcal{G}$ of open sets such that whenever x, y are distinct points in X there are disjoint G, $H \in \mathcal{G}$ such that $x \in G$ and $y \in H$.

(g) If X is a regular topological space with a countable network, it has a countable network consisting of closed sets.

(h) A compact Hausdorff space with a countable network is metrizable.

(i) If a topological space X has a countable network, then any dense set in X includes a countable dense set; in particular, X is separable.

(j) If a topological space X has a countable network, then $C(X)$, with the topology of pointwise convergence inherited from the product topology of $\mathbb{R}^X$, has a countable network.

proof (a) If $\mathcal{E}$ is a countable network for the topology of X, and $Y \subseteq X$, then $\{Y \cap E : E \in \mathcal{E}\}$ is a countable network for the topology of Y.

(b) By Engelking 89, 3.8.12 X is Lindelöf. Since any subspace of X has a countable network ((a) above), it also is Lindelöf, and X is hereditarily Lindelöf. By 4A2H(c-ii), if X is regular, closed sets are zero sets.

(c) If $\mathcal{E}_n$ is a countable network for the topology of A_n for each n, then $\bigcup_{n\in\mathbb{N}} \mathcal{E}_n$ is a countable network for the topology of A.

(d) Let X be a topological space with a countable network $\mathcal{E}$, and Y a continuous image of X. Let $f : X \to Y$ be a continuous surjection. Then $\{f[E] : E \in \mathcal{E}\}$ is a network for the topology of Y. **P** If $H \subseteq Y$ is open and $y \in H$, then $f^{-1}[H]$ is an open subset of X and there is an $x \in X$ such that $f(x) = y$. Now there must be an $E \in \mathcal{E}$ such that $x \in E \subseteq f^{-1}[H]$, so that $y \in f[E] \subseteq H$. **Q** But $\{f[E] : E \in \mathcal{E}\}$ is countable, so Y has a countable network.

(e) For each $i \in I$ let $\mathcal{E}_i$ be a countable network for the topology of X_i. For each finite $J \subseteq I$, let $\mathcal{C}_J$ be the family of sets expressible as $\prod_{i\in I} E_i$ where $E_i \in \mathcal{E}_i$ for each $i \in J$ and $E_i = X_i$ for $i \in I \setminus J$; then $\mathcal{C}_J$ is countable because $\mathcal{E}_i$ is countable for each $i \in J$. Because the family $[I]^{<\omega}$ of finite subsets of I is countable (3A1Cd), $\mathcal{E} = \bigcup\{\mathcal{C}_J : J \in [I]^{<\omega}\}$ is countable. But $\mathcal{E}$ is a network for the topology of X. **P** If $G \subseteq X$ is open and $x \in G$, then there is a family $\langle G_i\rangle_{i\in I}$ such that every $G_i \subseteq X_i$ is open, $J = \{i : G_i \neq X_i\}$ is finite, and $x \in \prod_{i\in I} G_i$. For $i \in J$, there is an $E_i \in \mathcal{E}_i$ such that $x(i) \in E_i \subseteq G_i$; set $E_i = X_i$ for $i \in I \setminus J$. Then

$$E = \prod_{i\in I} E_i \in \mathcal{C}_J \subseteq \mathcal{E}$$

and $x \in E \subseteq G$. **Q**

So $\mathcal{E}$ is a countable network for the topology of X.

(f) By (b) and (e), $X \times X$ is hereditarily Lindelöf. In particular, $W = \{(x, y) : x \neq y\}$ is Lindelöf. Set

$$\mathcal{V} = \{G \times H : G, H \subseteq X \text{ are open}, G \cap H = \emptyset\}.$$

Because X is Hausdorff, $\mathcal{V}$ is a cover of W. So there is a countable $\mathcal{V}_0 \subseteq \mathcal{V}$ covering W. Set

$$\mathcal{G} = \{G : G \times H \in \mathcal{V}_0\} \cup \{H : G \times H \in \mathcal{V}_0\}.$$

Then $\mathcal{G}$ is a countable family of open sets separating the points of X.

(g) Let X be a regular space and $\mathcal{E}$ a countable network for the topology of X. Set $\mathcal{E}' = \{\overline{E} : E \in \mathcal{E}\}$. If $G \subseteq X$ is open and $x \in G$, then (because the topology is regular) there is an open set H such that $x \in H \subseteq \overline{H} \subseteq G$. Now there is an $E \in \mathcal{E}$ such that $x \in E \subseteq H$, in which case $\overline{E} \in \mathcal{E}'$ and $x \in \overline{E} \subseteq G$. So $\mathcal{E}'$ is a countable network for X consisting of closed sets.

(h) Engelking 89, 3.1.19.

(i) Let $D \subseteq X$ be dense, and $\mathcal{E}$ a countable network for the topology of X. Let $D' \subseteq D$ be a countable set such that $D' \cap E \neq \emptyset$ whenever $E \in \mathcal{E}$ and $D \cap E \neq \emptyset$. If $G \subseteq X$ is open and not empty, there is an $x \in D \cap G$; now there is an $E \in \mathcal{E}$ such that $x \in E \subseteq G$, and as $x \in D \cap E$ there must be an $x' \in D' \cap E$, so that $x' \in D' \cap G$. As G is arbitrary, D' is dense in X.

Taking $D = X$, we see that X has a countable dense subset.

(j) Let $\mathcal{E}$ be a countable network for the topology of X and $\mathcal{U}$ a countable base for the topology of $\mathbb{R}$ (4A2Ua). For $E \in \mathcal{E}$, $U \in \mathcal{U}$ set $H(E,U) = \{f : f \in C(X), E \subseteq f^{-1}[U]\}$. Then the set of finite intersections of sets of the form $H(E,U)$ is a countable network for the topology of pointwise convergence on $C(X)$. (Compare 4A2Oe.)

4A2O Second-countable spaces (a) Let $(X,\mathfrak{T})$ be a topological space and $\mathcal{U}$ a countable subbase for $\mathfrak{T}$. Then $\mathfrak{T}$ is second-countable. ($\{X\} \cup \{U_0 \cap U_1 \cap \ldots \cap U_n : U_0, \ldots, U_n \in \mathcal{U}\}$ is countable and is a base for $\mathfrak{T}$, by 4A2B(a-i).)

(b) Any base of a second-countable space includes a countable base. (Császár 78, 2.4.17.)

(c) Let $(X,\mathfrak{T})$ be a second-countable space. $\mathfrak{T}$ has a countable network (because a base is also a network), so is separable and hereditarily Lindelöf (Engelking 89, 1.3.8 & 3.8.1, 4A2Nb, 4A2Ni).

(d) The product of a countable family of second-countable spaces is second-countable. (Engelking 89, 2.3.14.)

(e) If X is a second-countable space then $C(X)$, with the topology of uniform convergence on compact sets, has a countable network. **P** (See Engelking 89, Ex. 3.4H.) Let $\mathcal{U}$ be a countable base for the topology of X and $\mathcal{V}$ a countable base for the topology of $\mathbb{R}$ (4A2Ua). For $U \in \mathcal{U}$, $V \in \mathcal{V}$ set $H(U,V) = \{f : f \in C(X), U \subseteq f^{-1}[V]\}$. Then the set of finite intersections of sets of the form $H(U,V)$ is a countable network for the topology of uniform convergence on compact subsets of X. **Q**

4A2P Separable metrizable spaces (a) (i) A metrizable space is second-countable iff it is separable. (Engelking 89, 4.1.16; Császár 78, 2.4.16; Gall p. 120.)

(ii) A compact metrizable space is separable (Engelking 89, 4.1.18; Császár 78, 5.3.35; Kuratowski 66, §21.IX), so is second-countable and has a countable network.

(iii) Any base of a separable metrizable space includes a countable base (4A2Ob), which is also a countable network, so the space is hereditarily Lindelöf (4A2Nb).

(iv) Any subspace of a separable metrizable space is separable and metrizable (4A2La, 4A2Na, 4A2Ni).

(v) A countable product of separable metrizable spaces is separable and metrizable (4A2B(e-ii), 4A2Lh).

(b) A topological space is separable and metrizable iff it is second-countable, regular and Hausdorff. (Engelking 89, 4.2.9; Császár 78, 7.1.57; Kuratowski 66, §22.II.)

(c) Let X be a compact metrizable space, Y a Hausdorff space and $f : X \to Y$ a continuous surjection. Then Y is metrizable. (It is a compact Hausdorff space, by 2A3N(b-ii), with a countable network, by 4A2Nd, so is metrizable, by 4A2Nh.)

(d) A metrizable space is separable iff it is ccc iff it is Lindelöf. (Engelking 89, 4.1.16.)

(e) If X is a compact metrizable space, then $C(X)$ is separable under its usual norm topology defined from the norm $\| \|_\infty$. (Engelking, 3.4.16.)

4A2Q Polish spaces: Proposition (a) A countable discrete space is Polish.

(b) A compact metrizable space is Polish.

(c) The product of a countable family of Polish spaces is Polish.

(d) A G_δ subset of a Polish space is Polish in its subspace topology; in particular, a set which is either open or closed is Polish.

(e) The disjoint union of countably many Polish spaces is Polish.

(f) If X is any set and $\langle \mathfrak{T}_n \rangle_{n\in\mathbb{N}}$ is a sequence of Polish topologies on X such that $\mathfrak{T}_m \cap \mathfrak{T}_n$ is Hausdorff for all $m, n \in \mathbb{N}$, then the topology $\mathfrak{T}_\infty$ generated by $\bigcup_{n\in\mathbb{N}} \mathfrak{T}_n$ is Polish.

(g) If X is a Polish space, it is homeomorphic to a G_δ set in a compact metric space.

proof (a) Any set X is complete under the discrete metric ρ defined by setting $\rho(x,y) = 1$ whenever x, $y \in X$ are distinct. This defines the discrete topology, and if X is countable it is separable, therefore Polish.

(b) By 4A2P(a-ii), it is separable; by 4A2Jd, any metric defining the topology is complete.

(c) If $\langle X_i\rangle_{i\in I}$ is a countable family of Polish spaces with product X, then surely X is separable (4A2B(e-ii)); and 4A2Mb tells us that its topology is defined by a complete metric.

(d) If X is Polish and E is a G_δ set in X, then E is separable, by 4A2P(a-iv), and its topology is defined by a complete metric, by 4A2Mc. So E is Polish. Any open set is of course a G_δ set, and any closed set is a G_δ set by 4A2Lc.

(e) Let $\langle X_i\rangle_{i\in I}$ be a countable disjoint family of Polish spaces, and $X = \bigcup_{i\in I} X_i$. For each $i \in I$ let ρ_i be a complete metric on X_i defining the topology of X_i. Define $\rho : X \times X \to [0,\infty[$ by setting $\rho(x,y) = \min(1, \rho_i(x,y))$ if $i \in I$ and x, $y \in X_i$, $\rho(x,y) = 1$ otherwise. It is easy to check that ρ is a complete metric on X defining the disjoint union topology on X. X is separable, by 4A2B(e-i), therefore Polish.

(f) This result is in Kechris 95, 13.3; but I spell out the proof because it is an essential element of some measure-theoretic arguments. On $X^{\mathbb{N}}$ take the product topology $\mathfrak{T}$ of the topologies $\mathfrak{T}_n$. This is Polish, by (c). Consider the diagonal $\Delta = \{x : x \in X^{\mathbb{N}}, x(m) = x(n) \text{ for all } m, n \in \mathbb{N}\}$. This is closed in $X^{\mathbb{N}}$. **P** If $x \in X^{\mathbb{N}} \setminus \Delta$, let m, $n \in \mathbb{N}$ be such that $x(m) \neq x(n)$. Because $\mathfrak{T}_m \cap \mathfrak{T}_n$ is Hausdorff, there are disjoint G, $H \in \mathfrak{T}_m \cap \mathfrak{T}_n$ such that $x(m) \in G$ and $x(n) \in H$. Now $\{y : y \in X^{\mathbb{N}}, y(m) \in G, y(n) \in H\}$ is an open set in $X^{\mathbb{N}}$ containing x and disjoint from Δ. As x is arbitrary, Δ is closed. **Q**

By (d), Δ, with its subspace topology, is a Polish space. Let $f : X \to \Delta$ be the natural bijection, setting $f(t) = x$ if $x(n) = t$ for every n, and let $\mathfrak{S}$ be the topology on X which makes f a homeomorphism. The topology on Δ is generated by $\{\{x : x \in \Delta, x(n) \in G\} : n \in \mathbb{N}, G \in \mathfrak{T}_n\}$, so $\mathfrak{S}$ is generated by $\{\{t : t \in X, t \in G\} : n \in \mathbb{N}, G \in \mathfrak{T}_n\} = \bigcup_{n\in\mathbb{N}} \mathfrak{T}_n$. Thus $\mathfrak{S} = \mathfrak{T}_\infty$ and $\mathfrak{T}_\infty$ is Polish.

(g) Kechris 95, 4.14.

4A2R Order topologies Let $(X, \leq)$ be a totally ordered set and $\mathfrak{T}$ its order topology.

(a) The set $\mathcal{U}$ of open intervals in X (definition: 4A2A) is a base for $\mathfrak{T}$.

(b) $[x,y]$, $[x,\infty[$ and $]-\infty,x]$ are closed sets for all x, $y \in X$.

(c) $\mathfrak{T}$ is Hausdorff and normal.

(d) If $A \subseteq X$ then $\overline{A}$ is the set of elements of X expressible as either suprema or infima of non-empty subsets of A.

(e) $F \subseteq X$ is closed iff it is order-closed.

(f) If $\langle x_n\rangle_{n\in\mathbb{N}}$ is a non-decreasing sequence in X with supremum x, then $x = \lim_{n\to\infty} x_n$.

(g) A set $K \subseteq X$ is compact iff $\sup A$ and $\inf A$ are defined in X and belong to K for every non-empty $A \subseteq K$.

(h) X is Dedekind complete iff $[x,y]$ is compact for all x, $y \in X$.

(i) X is compact iff it is either empty or Dedekind complete with greatest and least elements.

(j) If X is Dedekind complete, any open set $G \subseteq X$ is expressible as a union of disjoint open intervals.

(k) If X is well-ordered it is locally compact.

(l) In $X \times X$, $\{(x,y) : x < y\}$ is open and $\{(x,y) : x \leq y\}$ is closed.

(m) If $F \subseteq X$ is *either* compact *or* an interval, then the subspace topology on F is induced by the inherited order of F.

(n) If X is ccc it is hereditarily Lindelöf, therefore perfectly normal.

(o) If Y is another totally ordered set with its order topology, an order-preserving function from X to Y is continuous iff it is order-continuous.

proof (a) Put the definition of 'order topology' (4A2A) together with 4A2B(a-i).

(b) Their complements are either X, or members of $\mathcal{U}$, or unions of two members of $\mathcal{U}$.

(c) Fix a well-ordering $\preccurlyeq$ of X. If $x < y \in X$, define U_{xy}, U_{yx} as follows: if $]x,y[$ is empty, $U_{xy} =]-\infty,x] =]-\infty,y[$ and $U_{yx} = [y,\infty[=]x,\infty[$; otherwise, let z be the $\preccurlyeq$-least member of $]x,y[$ and set $U_{xy} =]-\infty,z[$, $U_{yx} =]z,\infty[$.

This construction ensures that if x, y are any distinct points of X, U_{xy} and U_{yx} are disjoint open sets containing x, y respectively, so $\mathfrak{T}$ is Hausdorff.

Now suppose that $F \subseteq X$ is closed and that $x \in X \setminus F$. Then $V_{xF} = \operatorname{int}(X \cap \bigcap_{y \in F} U_{xy})$ contains x. **P** There are u, $v \in X \cup \{-\infty, \infty\}$ such that $x \in]u, v[\subseteq X \setminus F$. If $]u, x[= \emptyset$, set $u' = u$; otherwise, let u' be the $\preccurlyeq$-least member of $]u, x[$. Similarly, if $]x, v[= \emptyset$, set $v' = v$; otherwise, let v' be the $\preccurlyeq$-least member of $]x, v[$. Then $u' < x < v'$. Now suppose that $y \in F$ and $y > x$. If $]x, v[= \emptyset$, then $U_{xy} \supseteq]-\infty, x] =]-\infty, v'[$. Otherwise, $v' \in]x, v[\subseteq]x, y[$, so $U_{xy} =]-\infty, z[$ where z is the $\preccurlyeq$-least member of $]x, y[$. But this means that $z \preccurlyeq v'$ and either $z = v'$ or $z \notin]x, v[$; in either case, $v' \leq z$ and $]-\infty, v'[\subseteq U_{xy}$.

Similarly, $]u', \infty[\subseteq U_{xy}$ whenever $y \in F$ and $y < x$. So $x \in]u', v'[\subseteq V_{xF}$. **Q**

Finally, suppose that E and F are disjoint closed sets. Set $G = \bigcup_{x \in E} V_{xF}$, $H = \bigcup_{y \in F} V_{yE}$. Then G and H are open sets including E, F respectively. If $x \in E$ and $y \in F$, then $V_{xF} \cap V_{yE} \subseteq U_{xy} \cap U_{yx} = \emptyset$, so $G \cap H = \emptyset$. As E and F are arbitrary, $\mathfrak{T}$ is normal.

(d) Let B be the set of such suprema and infima. For $x \in X$ set $A_x = A \cap]-\infty, x]$, $A'_x = A \cap [x, \infty[$. Then $x \in B$ iff either $x = \sup A_x$ or $x = \inf A'_x$, so

$$\begin{aligned} x \notin B &\iff x \neq \sup A_x \text{ and } x \neq \inf A'_x \\ &\iff \text{there are } u < x,\ v > x \text{ such that } A_x \subseteq]-\infty, u] \text{ and } A'_x \subseteq [u, \infty[\\ &\iff \text{there are } u,\ v \text{ such that } x \in]u, v[\subseteq X \setminus A \\ &\iff x \notin \overline{A}. \end{aligned}$$

Thus $B = \overline{A}$, as claimed.

(e) Because X is totally ordered, all its subsets are both upwards-directed and downwards-directed; so we have only to join the definition in 313Da to (d) above.

(f) If $x \in]u, v[$ then there is some $n \in \mathbb{N}$ such that $x_n \geq u$, and now $x_i \in]u, v[$ for every $i \geq n$.

(g)(α) If K is compact and $A \subseteq K$ is non-empty, let B be the set of upper bounds for A in $X \cup \{-\infty, \infty\}$, and set $\mathcal{G} = \{]-\infty, a[: a \in A\} \cup \{]b, \infty[: b \in B\}$. Then no finite subfamily of $\mathcal{G}$ can cover K; and if $c \in K \setminus \bigcup \mathcal{G}$ then $c = \sup A$. Similarly, any non-empty subset of K has an infimum in X which belongs to K.

(β) Now suppose that K satisfies the condition. By (d) above, it is closed. If it is empty it is certainly compact. Otherwise, $a_0 = \inf K$ and $b_0 = \sup K$ are defined in X and belong to K. Let $\mathcal{G}$ be an open cover of K. Set

$$A = \{x : x \in X,\ K \cap [a_0, x] \text{ is not covered by any finite } \mathcal{G}_0 \subseteq \mathcal{G}\}.$$

Note that A is bounded below by a_0. **?** If $b_0 \in A$, then $c = \inf A$ is defined and belongs to $[a_0, b_0]$, because X is Dedekind complete. If $c \notin K$ then there are u, v such that $c \in]u, v[\subseteq X \setminus K$; if $c \in K$ then there are u, v such that $c \in]u, v[\subseteq G$ for some $G \in \mathcal{G}$. In either case, $u \notin A$, so that $K \cap [a_0, v[\subseteq (K \cap [a_0, u]) \cup]u, v[$ is covered by a finite subset of $\mathcal{G}$, and A does not meet $[a_0, v[$, that is, $A \subseteq [v, \infty[$ and v is a lower bound of A. **X** Thus $b_0 \notin A$, and $K = K \cap [a_0, b_0]$ is covered by a finite subset of $\mathcal{G}$. As $\mathcal{G}$ is arbitrary, K is compact.

(h) Use (g).

(i) Use (h).

(j) Gaal 64, p. 36. (Compare 2A2I.)

(k) Use (h).

(l) Write W for $\{(x, y) : x < y\}$. If $x < y$, then either there is a z such that $x < z < y$, in which case $]-\infty, z[\times]z, \infty[$ is an open set containing (x, y) and included in W, or $]x, y[= \emptyset$, so $]-\infty, y[\times]x, \infty[$ is an open set containing (x, y) and included in W. Thus W is open.

Now $\{(x, y) : x \leq y\} = (X \times X) \setminus \{(x, y) : y < x\}$ is closed.

(m) The subspace topology $\mathfrak{T}_F$ on F is generated by sets of the form $F \cap]-\infty, x[$, $F \cap]x, \infty[$ where $x \in X$ (4A2B(a-iv)), while the order topology $\mathfrak{S}$ on F is generated by sets of the form $F \cap]-\infty, x[$, $F \cap]x, \infty[$ where $x \in F$. So $\mathfrak{S} \subseteq \mathfrak{T}_F$.

Now suppose that F is either compact or an interval, and that $x \in X$. If $x \in F$, or $F \cap]-\infty, x[$ is either F or $\emptyset$, then of course $F \cap]-\infty, x[\in \mathfrak{S}$. Otherwise, F meets both $]-\infty, x[$ and $[x, \infty[$ and does not contain

x, so is not an interval, and is compact. Accordingly $x' = \inf(F \cap [x, \infty[)$ is defined and belongs to F, by (g), and $F \cap]-\infty, x[= F \cap]-\infty, x'[\in \mathfrak{S}$.

Similarly, $F \cap]x, \infty[\in \mathfrak{S}$ for every $x \in X$. But this means that $\mathfrak{T}_F \subseteq \mathfrak{S}$, so the two topologies are equal, as stated.

(n)(α) Let $\mathcal{G}$ be a family of open subsets of X with union H. Set

$$\mathcal{A} = \{A : A \subseteq \bigcup \mathcal{G}_0 \text{ for some countable } \mathcal{G}_0 \subseteq \mathcal{G}\}.$$

(I seek to show that $H \in \mathcal{A}$.) Of course $\bigcup \mathcal{A}_0 \in \mathcal{A}$ for every countable subset $\mathcal{A}_0$ of $\mathcal{A}$.

(β) Let $\mathcal{C}$ be the family of members C of $\mathcal{A}$ which are order-convex (that is, $[x, y] \subseteq C$ for all x, $y \in C$), and $\mathcal{C}^*$ the family of maximal members of $\mathcal{C}$. If $C \in \mathcal{C}$ is not included in any member of $\mathcal{C}^*$, then there is a $C' \in \mathcal{C}$ such that $C \subseteq C'$ and $\operatorname{int}(C' \setminus C) \neq \emptyset$. **P** Since no member of $\mathcal{C}$ including C can be maximal, we can find $C' \in \mathcal{C}$ such that $C \subseteq C'$ and $\#(C' \setminus C) \geq 5$. Because C is order-convex, every point of $X \setminus C$ is either a lower bound or an upper bound of C, and there must be three points $x < y < z$ of $C' \setminus C$ on the same side of C. In this case,

$$y \in]x, z[\subseteq \operatorname{int}(C' \setminus C),$$

so we have an appropriate C'. **Q**

(γ) In fact, every member of $\mathcal{C}$ is included in a member of $\mathcal{C}^*$. **P?** Suppose, if possible, otherwise. Then we can choose a strictly increasing family $\langle C_\xi \rangle_{\xi < \omega_1}$ in $\mathcal{C}$ inductively, as follows. Start from any non-empty $C_0 \in \mathcal{C}$ not included in any member of $\mathcal{C}^*$. Given that $C_0 \subseteq C_\xi \in \mathcal{C}$, then C_ξ cannot be included in any member of $\mathcal{C}^*$, so by (β) above there is a $C_{\xi+1} \in \mathcal{C}$ such that $\operatorname{int}(C_{\xi+1} \setminus C_\xi)$ is non-empty. Given $\langle C_\eta \rangle_{\eta < \xi}$ where $\xi < \omega_1$ is a non-zero countable limit ordinal, set $C_\xi = \bigcup_{\eta < \xi} C_\eta$; then C_ξ is order-convex, because $\{C_\eta : \eta < \xi\}$ is upwards-directed, and belongs to $\mathcal{A}$, because $\mathcal{A}$ is closed under countable unions, so $C_\xi \in \mathcal{C}$ and the induction proceeds.

Now, however, $\langle \operatorname{int}(C_{\xi+1} \setminus C_\xi) \rangle_{\xi < \omega_1}$ is an uncountable disjoint family of non-empty open sets, and X is not ccc. **XQ**

(δ) Since $C \cup C'$ is order-convex whenever C, $C' \in \mathcal{C}$ and $C \cap C' \neq \emptyset$, $\mathcal{C}^*$ is a disjoint family. Moreover, if $x \in H$, there is some open interval containing x and belonging to $\mathcal{C}$, so $x \in \operatorname{int} C$ for some $C \in \mathcal{C}^*$; this shows that $\mathcal{C}^*$ is an open cover of H. Because X is ccc, $\mathcal{C}^*$ is countable, so $H = \bigcup \mathcal{C}^* \in \mathcal{A}$. Thus there is some countable $\mathcal{G}_0 \subseteq \mathcal{G}$ with union H; as $\mathcal{G}$ is arbitrary, X is hereditarily Lindelöf, by 4A2H(c-i).

(ϵ) By 4A2H(c-ii), X is perfectly normal.

(o)(α) Suppose that f is continuous. If $A \subseteq X$ is a non-empty set with supremum x in X, then $x \in \overline{A}$, by (d), so $f(x) \in \overline{f[A]}$ (3A3Cc) and $f(x)$ is less than or equal to any upper bound of $f[A]$; but $f(x)$ is an upper bound of $f[A]$, because f is order-preserving, so $f(x) = \sup f[A]$. Similarly, $f(\inf A) = \inf f[A]$ whenever A is non-empty and has an infimum, so f is order-continuous.

(β) Now suppose that f is order-continuous. Take any $y \in Y$ and consider $A = f^{-1}[\,]-\infty, y[\,]$, $B = X \setminus A$. If $x \in A$ then $f(x)$ cannot be $\inf f[B]$ so x cannot be $\inf B$ and there is an $x' \in X$ such that $x < x' \leq z$ for every $z \in B$; in which case $x \in]-\infty, x'[\subseteq A$. So A is open. Similarly, $f^{-1}[\,]y, \infty[\,]$ is open. By 4A2B(a-ii), f is continuous.

4A2S Order topologies on ordinals (a) Let ζ be an ordinal with its order topology.

(i) ζ is locally compact (4A2Rk); all the sets $[0, \eta] =]-\infty, \eta + 1[$, for $\eta < \zeta$, are open and compact (4A2Rh). If ζ is a successor ordinal, it is compact, being of the form $[0, \eta]$ where $\zeta = \eta + 1$.

(ii) For any $A \subseteq \zeta$, $\overline{A} = \{\sup B : \emptyset \neq B \subseteq A, \sup B < \zeta\}$. (4A2Rd, because $\inf B \in B \subseteq A$ for every non-empty $B \subseteq A$.)

(iii) If $\xi \leq \zeta$, then the subspace topology on ξ induced by the order topology of ζ is the order topology of ξ. (4A2Rm.)

(b) Give ω_1 its order topology.

(i) ω_1 is first-countable. **P** If $\xi < \omega_1$ is either zero or a successor ordinal, then $\{\xi\}$ is open so $\{\{\xi\}\}$ is a base of neighbourhoods of ξ. If ξ is a non-zero limit ordinal, there is a sequence $\langle \xi_n \rangle_{n \in \mathbb{N}}$ in ξ with supremum ξ, and $\{]\xi_n, \xi] : n \in \mathbb{N}\}$ is a base of neighbourhoods of ξ. **Q**

(ii) Singleton subsets of ω_1 are zero sets. (Assemble 4A2F(d-v), 4A2Rc and (i) above.)

(iii) If $f : \omega_1 \to \mathbb{R}$ is continuous, there is a $\xi < \omega_1$ such that $f(\eta) = f(\xi)$ for every $\eta \geq \xi$. **P?** Otherwise, we may define a strictly increasing family $\langle \zeta_\xi \rangle_{\xi<\omega_1}$ in ω_1 by saying that $\zeta_0 = 0$,

$$\zeta_{\xi+1} = \min\{\eta : \eta > \zeta_\xi,\, f(\eta) \neq f(\zeta_\xi)\}$$

for every $\xi < \omega_1$,

$$\zeta_\xi = \sup\{\zeta_\eta : \eta < \xi\}$$

for non-zero countable limit ordinals ξ. Now

$$\omega_1 = \textstyle\bigcup_{k\in\mathbb{N}} \{\xi : |f(\zeta_{\xi+1}) - f(\zeta_\xi)| \geq 2^{-k}\},$$

so there is a $k \in \mathbb{N}$ such that $A = \{\xi : |f(\zeta_{\xi+1}) - f(\zeta_\xi)| \geq 2^{-k}\}$ is infinite. Take a strictly increasing sequence $\langle \xi_n \rangle_{n\in\mathbb{N}}$ in A and set $\xi = \sup_{n\in\mathbb{N}} \xi_n = \sup_{n\in\mathbb{N}} (\xi_n + 1)$. Then $\langle \zeta_{\xi_n} \rangle_{n\in\mathbb{N}}$ and $\langle \zeta_{\xi_n+1} \rangle_{n\in\mathbb{N}}$ are strictly increasing sequences with supremum ζ_ξ, so both converge to ζ_ξ in the order topology of ω_1 (4A2Rf), and

$$f(\zeta_\xi) = \lim_{n\to\infty} f(\zeta_{\xi_n}) = \lim_{n\to\infty} f(\zeta_{\xi_n+1}).$$

But this means that

$$\lim_{n\to\infty} f(\zeta_{\xi_n}) - f(\zeta_{\xi_n+1}) = 0,$$

which is impossible, because $|f(\zeta_{\xi_n}) - f(\zeta_{\xi_n+1})| \geq 2^{-k}$ for every n. **XQ**

4A2T Upper limits of families of sets For the sake of §446 I outline some elementary ideas. Let X be a topological space, $\langle A_i \rangle_{i\in I}$ a family of subsets of X, and $\mathcal{F}$ a filter on I.

(a) $\limsup_{i\to\mathcal{F}} A_i$ is closed. If $F \subseteq X$ is closed and $A_i \subseteq F$ for every i, then $\limsup_{i\to\mathcal{F}} A_i \subseteq F$. If $\langle B_i \rangle_{i\in I}$ is another family of sets, and $B_i \subseteq A_i$ for every i, then $\limsup_{i\to\mathcal{F}} B_i \subseteq \limsup_{i\to\mathcal{F}} A_i$. If $x \in A_i$ for every i then $x \in \limsup_{i\to\mathcal{F}} A_i$. (Immediate from the definition in 4A2A.)

If X is Hausdorff, $x_i \in A_i$ for every i and $x = \lim_{i\to\mathcal{F}} x_i$ is defined in X, then $x \in \limsup_{i\to\mathcal{F}} A_i$. ($\limsup_{i\to\mathcal{F}} \{x_i\} = \{x\}$.)

If $f : X \to X$ is a homeomorphism then $f[\limsup_{i\to\mathcal{F}} A_i] = \limsup_{i\to\mathcal{F}} f[A_i]$.

(b) If $K \subseteq X$ is compact and $K \cap \limsup_{i\to\mathcal{F}} A_i = \emptyset$, then $\{i : A_i \cap K = \emptyset\} \in \mathcal{F}$. ($\{K \cap \overline{\bigcup_{i\in J} A_i} : J \in \mathcal{F}\}$ is a downwards-directed family of relatively closed subsets of K with empty intersection, so contains $\emptyset$.)

(c) Suppose that $\mathcal{F}$ is an ultrafilter. If $G \subseteq X$ is open and $G \cap \limsup_{i\to\mathcal{F}} A_i \neq \emptyset$ then $\{i : G \cap A_i \neq \emptyset\} \in \mathcal{F}$. (Otherwise, $J = \{i : G \cap A_i = \emptyset\} \in \mathcal{F}$ and

$$\limsup_{i\to\mathcal{F}} A_i \subseteq \overline{\textstyle\bigcup_{i\in J} A_i} \subseteq X \setminus G.)$$

4A2U Old friends (a) $\mathbb{R}$, with its usual topology, is metrizable (2A3Ff) and separable (the countable set $\mathbb{Q}$ is dense), so is second-countable (4A2P(a-i)). Every subset of $\mathbb{R}$ is separable (4A2P(a-iv)); in particular, every dense subset of $\mathbb{R}$ has a countable subset which is still dense.

(b) $\mathbb{N}^\mathbb{N}$ is Polish in its usual topology (4A2Qc), so has a countable network (4A2P(a-iii), or 4A2Ne), and is hereditarily Lindelöf (4A2Nb or 4A2Pd). Moreover, it is homeomorphic to $[0,1] \setminus \mathbb{Q}$(Kuratowski 66, §36.II; Kechris 95, 7.7).

(c) The map $x \mapsto \frac{2}{3} \sum_{j=0}^\infty 3^{-j} x(j)$ (cf. 134Gb) is a homeomorphism between $\{0,1\}^\mathbb{N}$ and the Cantor set $C \subseteq [0,1]$. (It is a continuous bijection.)

(d) If I is any set, then the map $A \mapsto \chi A : \mathcal{P}I \to \{0,1\}^I$ is a homeomorphism (for the usual topologies on $\mathcal{P}I$ and $\{0,1\}^I$, as described in 4A2A and 3A3K). So $\mathcal{P}I$ is zero-dimensional, compact (3A3K) and Hausdorff. If I is countable, then $\mathcal{P}I$ is metrizable, therefore Polish (4A2Qb).

4A3 Topological σ-algebras

I devote a section to some σ-algebras which can be defined on topological spaces. While 'measures' will not be mentioned here, the manipulation of these σ-algebras is an essential part of the technique of measure theory, and I will give proofs and exercises as if this were part of the main work. I look at Borel σ-algebras (4A3A-4A3J), Baire σ-algebras (4A3K-4A3P), Baire property algebras (4A3Q, 4A3R) and cylindrical σ-algebras on linear spaces (4A3T-4A3V).

4A3A Borel sets If $(X, \mathfrak{T})$ is a topological space, the **Borel σ-algebra** of X is the σ-algebra $\mathcal{B}(X)$ of subsets of X generated by $\mathfrak{T}$. Its elements are the **Borel sets** of X. If $(Y, \mathfrak{S})$ is another topological space with Borel σ-algebra $\mathcal{B}(Y)$, a function $f : X \to Y$ is **Borel measurable** if $f^{-1}[H] \in \mathcal{B}(X)$ for every $H \in \mathfrak{S}$, and is a **Borel isomorphism** if it is a bijection and $\mathcal{B}(Y) = \{F : F \subseteq Y, f^{-1}[F] \in \mathcal{B}(X)\}$, that is, f is an isomorphism between the structures $(X, \mathcal{B}(X))$ and $(Y, \mathcal{B}(Y))$.

4A3B (Σ, T)**-measurable functions** It is time I put the following idea into bold type.

(a) Let X and Y be sets, with σ-algebras $\Sigma \subseteq \mathcal{P}X$ and $\mathrm{T} \subseteq \mathcal{P}Y$. A function $f : X \to Y$ is (Σ, T)**-measurable** if $f^{-1}[F] \in \Sigma$ for every $F \in \mathrm{T}$.

(b) If Σ, T and Υ are σ-algebras of subsets of X, Y and Z respectively, and $f : X \to Y$ is (Σ, T)-measurable while $g : Y \to Z$ is (T, Υ)-measurable, then $gf : X \to Z$ is (Σ, Υ)-measurable. (If $H \in \Upsilon$, $g^{-1}[H] \in \mathrm{T}$ so $(gf)^{-1}[H] = f^{-1}[g^{-1}[H]] \in \Sigma$.)

(c) Let $\langle X_i \rangle_{i \in I}$ be a family of sets with product X, Y another set, and $f : X \to Y$ a function. If $\mathrm{T} \subseteq \mathcal{P}Y$, $\Sigma_i \subseteq \mathcal{P}X_i$ are σ-algebras for each i, then f is $(\mathrm{T}, \widehat{\bigotimes}_{i \in I} \Sigma_i)$-measurable iff $\pi_i f : Y \to X_i$ is (T, Σ_i)-measurable for every i, where $\pi_i : X \to X_i$ is the coordinate map. **P** π_i is $(\widehat{\bigotimes}_{j \in I} \Sigma_j, \Sigma_i)$-measurable, so if f is $(\mathrm{T}, \widehat{\bigotimes}_{j \in I} \Sigma_j)$-measurable then $\pi_i f$ must be (T, Σ_i)-measurable. In the other direction, if every $\pi_i f$ is measurable, then $\{H : H \subseteq X, f^{-1}[E] \in \mathrm{T}\}$ is a σ-algebra of subsets of X containing $\pi_i^{-1}[E]$ whenever $i \in I$ and $E \in \Sigma_i$, so includes $\widehat{\bigotimes}_{i \in I} \Sigma_i$, and f is measurable. **Q**

4A3C Elementary facts (a) If X is a topological space and Y is a subspace of X, then $\mathcal{B}(Y)$ is just the subspace σ-algebra $\{E \cap Y : E \in \mathcal{B}(X)\}$. **P** $\{E : E \subseteq X, E \cap Y \in \mathcal{B}(Y)\}$ and $\{E \cap Y : E \in \mathcal{B}(X)\}$ are σ-algebras containing all open sets, so include $\mathcal{B}(X)$, $\mathcal{B}(Y)$ respectively. **Q**

(b) If X is a set, Σ is a σ-algebra of subsets of X, $(Y, \mathfrak{S})$ is a topological space and $f : X \to Y$ is a function, then f is $(\Sigma, \mathcal{B}(Y))$-measurable iff $f^{-1}[H] \in \Sigma$ for every $H \in \mathfrak{S}$. **P** If f is $(\Sigma, \mathcal{B}(Y))$-measurable then $f^{-1}[H] \in \Sigma$ for every $H \in \mathfrak{S}$ just because $\mathfrak{S} \subseteq \mathcal{B}(Y)$. If $f^{-1}[H] \in \Sigma$ for every $H \in \mathfrak{S}$, then $\{F : F \subseteq Y, f^{-1}[F] \in \Sigma\}$ is a σ-algebra of subsets of Y (cf. 112E) including $\mathfrak{S}$, so includes $\mathcal{B}$, and f is $(\Sigma, \mathcal{B})$-measurable. **Q**

(c) If X and Y are topological spaces, and $f : X \to Y$ is a function, then f is Borel measurable iff it is $(\mathcal{B}(X), \mathcal{B}(Y))$-measurable. (Apply (b) with $\Sigma = \mathcal{B}(X)$.) So if X, Y and Z are topological spaces and $f : X \to Y$, $g : Y \to Z$ are Borel measurable functions, then $gf : X \to Z$ is Borel measurable. (Use 4A3Bb.)

(d) If X and Y are topological spaces and $f : X \to Y$ is continuous, it is Borel measurable. (Immediate from the definitions in 4A3A.)

(e) If X is a topological space and $f : X \to [-\infty, \infty]$ is lower semi-continuous, then it is Borel measurable. (The inverse image of a half-open interval $]\alpha, \beta]$ is a difference of open sets, so is a Borel set, and every open subset of $[-\infty, \infty]$ is a countable union of such half-open intervals.)

(f) If $\langle X_i \rangle_{i \in I}$ is a family of topological spaces with product X, then $\mathcal{B}(X) \supseteq \widehat{\bigotimes}_{i \in I} \mathcal{B}(X_i)$. (Put (d) and 4A3Bc together.)

(g) Let X be a topological space.

(i) The algebra $\mathfrak{A}$ of subsets generated by the open sets is precisely the family of sets expressible as a disjoint union $\bigcup_{i\le n} G_i \cap F_i$ where every G_i is open and every F_i is closed. **P** Write $\mathcal{A}$ for the family of sets expressible in this form. Of course $\mathcal{A} \subseteq \mathfrak{A}$. In the other direction, observe that

$X \in \mathcal{A}$,

if E, $E' \in \mathcal{A}$ then $E \cap E' \in \mathcal{A}$,

if $E \in \mathcal{A}$ then $X \setminus E \in \mathcal{A}$

because if G_i is open and F_i is closed for $i \le n$, then (identifying $\{0, \dots, n\}$ with $n+1$)

$$\begin{aligned} X \setminus \bigcup_{i\le n} (G_i \cap F_i) &= \bigcap_{i\le n} (X \setminus G_i) \cup (G_i \setminus F_i) \\ &= \bigcup_{I \subseteq n+1} (\bigcap_{i\in I} (G_i \setminus F_i) \cap \bigcap_{i \in (n+1)\setminus I} (X \setminus G_i)) \end{aligned}$$

belongs to $\mathcal{A}$. So $\mathcal{A}$ is an algebra of sets and must be equal to $\mathfrak{A}$. **Q**

(ii) $\mathcal{B}(X)$ is the smallest family $\mathcal{E} \supseteq \mathfrak{A}$ such that $\bigcup_{n\in\mathbb{N}} E_n \in \mathcal{E}$ for every non-decreasing sequence $\langle E_n\rangle_{n\in\mathbb{N}}$ in $\mathcal{E}$ and $\bigcap_{n\in\mathbb{N}} E_n \in \mathcal{E}$ for every non-increasing sequence $\langle E_n\rangle_{n\in\mathbb{N}}$ in $\mathcal{E}$. (136G.)

4A3D Hereditarily Lindelöf spaces (a) Suppose that X is a hereditarily Lindelöf space and $\mathcal{U}$ is a subbase for the topology of X. Then $\mathcal{B}(X)$ is the σ-algebra of subsets of X generated by $\mathcal{U}$. **P** Write Σ for the σ-algebra generated by $\mathcal{U}$. Of course $\Sigma \subseteq \mathcal{B}(X)$ just because every member of $\mathcal{U}$ is open. In the other direction, set

$$\mathcal{V} = \{X\} \cup \{U_0 \cap U_1 \cap \dots \cap U_n : U_0, \dots, U_n \in \mathcal{U}\};$$

then $\mathcal{V} \subseteq \Sigma$ and $\mathcal{V}$ is a base for the topology of X (4A2B(a-i)). If $G \subseteq X$ is open, set $\mathcal{V}_1 = \{V : V \in \mathcal{V}, V \subseteq G\}$; then $G = \bigcup \mathcal{V}_1$. Because X is hereditarily Lindelöf, there is a countable set $\mathcal{V}_0 \subseteq \mathcal{V}_1$ such that $G = \bigcup \mathcal{V}_0$ (4A2H(c-i)), so that $G \in \Sigma$. Thus every open set belongs to Σ and $\mathcal{B}(X) \subseteq \Sigma$. **Q**

(b) Let X be a set, Σ a σ-algebra of subsets of X, Y a hereditarily Lindelöf space, $\mathcal{U}$ a subbase for the topology of Y, and $f : X \to Y$ a function. If $f^{-1}[U] \in \Sigma$ for every $U \in \mathcal{U}$, then f is $(\Sigma, \mathcal{B}(Y))$-measurable. **P** $\{F : F \subseteq Y, f^{-1}[F] \in \Sigma\}$ is a σ-algebra of subsets of Y including $\mathcal{U}$, so contains every open set, by (a). **Q**

(c) Let $\langle X_i\rangle_{i\in I}$ be a family of topological spaces with product X. Suppose that X is hereditarily Lindelöf.

(i) $\mathcal{B}(X) = \widehat{\bigotimes}_{i\in I} \mathcal{B}(X_i)$. **P** By 4A3Cf, $\mathcal{B}(X) \supseteq \widehat{\bigotimes}_{i\in I} \mathcal{B}(X_i)$. On the other hand, $\widehat{\bigotimes}_{i\in I} \mathcal{B}(X_i)$ is a σ-algebra including

$$\mathcal{U} = \{\pi_i^{-1}[G] : i \in I, G \subseteq X_i \text{ is open}\},$$

where $\pi_i(x) = x(i)$ for $i \in I$ and $x \in X$; since $\mathcal{U}$ is a subbase for the topology of X, (a) tells us that $\widehat{\bigotimes}_{i\in I} \mathcal{B}(X_i)$ includes $\mathcal{B}(X)$. **Q**

(ii) If Y is another topological space, then a function $f : Y \to X$ is Borel measurable iff $\pi_i f : Y \to X_i$ is Borel measurable for every $i \in I$, where $\pi_i : X \to X_i$ is the canonical map. (Use 4A3Bc.)

4A3E Applications Recall that any topological space with a countable network (in particular, any second-countable space, any separable metrizable space) is hereditarily Lindelöf (4A2Nb, 4A2Oc, 4A2P(a-iii)); and so is any ccc totally ordered space (4A2Rn). So 4A3Da-4A3Db will be applicable to these. As for product spaces, the product of a countable family of spaces with countable networks again has a countable network (4A2Ne), so for such spaces we shall be able to use 4A3Dc. For instance, $\mathcal{B}(\{0,1\}^{\mathbb{N}})$ is the σ-algebra of subsets of $\{0,1\}^{\mathbb{N}}$ generated by the sets $\{x : x(n) = 1\}$ for $n \in \mathbb{N}$.

4A3F Spaces with countable networks (a) Let X be a topological space with a countable network. Then $\#(\mathcal{B}(X)) \le \mathfrak{c}$. **P** Let $\mathcal{E}$ be a countable network for the topology of X and Σ the σ-algebra of subsets of X generated by $\mathcal{E}$. Then $\#(\Sigma) \le \mathfrak{c}$ (4A1O). If $G \subseteq X$ is open, there is a subset $\mathcal{E}'$ of $\mathcal{E}$ such that $\bigcup \mathcal{E}' = G$; but $\mathcal{E}'$ is necessarily countable, so $G \in \Sigma$. It follows that $\mathcal{B}(X) \subseteq \Sigma$ and $\#(\mathcal{B}(X)) \le \mathfrak{c}$. **Q**

(b) $\#(\mathcal{B}(\mathbb{N}^{\mathbb{N}})) = \mathfrak{c}$. **P** $\mathbb{N}^{\mathbb{N}}$ has a countable network (4A2Ub), so $\#(\mathcal{B}(\mathbb{N}^{\mathbb{N}})) \leq \mathfrak{c}$. On the other hand, $\mathcal{B}(\mathbb{N}^{\mathbb{N}})$ contains all singletons, so

$$\#(\mathcal{B}(\mathbb{N}^{\mathbb{N}})) \geq \#(\mathbb{N}^{\mathbb{N}}) \geq \#(\{0,1\}^{\mathbb{N}}) = \mathfrak{c}. \quad \mathbf{Q}$$

4A3G Second-countable spaces Suppose that X is a second-countable space and Y is any topological space. Then $\mathcal{B}(X \times Y) = \mathcal{B}(X)\widehat{\otimes}\mathcal{B}(Y)$. **P** By 4A3Cf, $\mathcal{B}(X \times Y) \supseteq \mathcal{B}(X)\widehat{\otimes}\mathcal{B}(Y)$. On the other hand, let $\mathcal{U}$ be a countable base for the topology of X. If $W \subseteq X \times Y$ is open, set

$$V_U = \bigcup\{H : H \subseteq Y \text{ is open}, U \times H \subseteq W\}$$

for $U \in \mathcal{U}$. Then $W = \bigcup_{U \in \mathcal{U}} U \times V_U$ belongs to $\mathcal{B}(X)\widehat{\otimes}\mathcal{B}(Y)$. As W is arbitrary, $\mathcal{B}(X \times Y) \subseteq \mathcal{B}(X)\widehat{\otimes}\mathcal{B}(Y)$. **Q**

4A3H Borel sets in Polish spaces: Proposition Let $(X, \mathfrak{T})$ be a Polish space and $E \subseteq X$ a Borel set. Then there is a Polish topology $\mathfrak{S}$ on X, including $\mathfrak{T}$, for which E is open.

proof Let $\mathcal{E}$ be the union of all the Polish topologies on X including $\mathfrak{T}$. Of course $X \in \mathcal{E}$. If $E \in \mathcal{E}$ then $X \setminus E \in \mathcal{E}$. **P** There is a Polish topology $\mathfrak{S} \supseteq \mathfrak{T}$ such that $E \in \mathfrak{S}$. Now both E and $X \setminus E$ are Polish in the subspace topologies $\mathfrak{S}_E$, $\mathfrak{S}_{X \setminus E}$ induced by $\mathfrak{S}$ (4A2Qd), so the disjoint union topology $\mathfrak{S}'$ of $\mathfrak{S}_E$ and $\mathfrak{S}_{X \setminus E}$ is also Polish (4A2Qe). Now $\mathfrak{S}' \supseteq \mathfrak{S} \supseteq \mathfrak{T}$ and $X \setminus E \in \mathfrak{S}'$, so $X \setminus E \in \mathcal{E}$. **Q** Moreover, the union of any sequence $\langle E_n \rangle_{n \in \mathbb{N}}$ in $\mathcal{E}$ belongs to $\mathcal{E}$. **P** For each $n \in \mathbb{N}$ let $\mathfrak{S}_n \supseteq \mathfrak{T}$ be a Polish topology containing E_n. If m, $n \in \mathbb{N}$ then $\mathfrak{S}_m \cap \mathfrak{S}_n$ includes $\mathfrak{T}$, so is Hausdorff. By 4A2Qf, the topology $\mathfrak{S}$ generated by $\bigcup_{n \in \mathbb{N}} \mathfrak{S}_n$ is Polish. Of course $\mathfrak{S} \supseteq \mathfrak{T}$, and $\bigcup_{n \in \mathbb{N}} E_n \in \mathfrak{S}$, so $\bigcup_{n \in \mathbb{N}} E_n \in \mathcal{E}$. **Q**

Thus $\mathcal{E}$ is a σ-algebra. Since it surely includes $\mathfrak{T}$, it includes $\mathcal{B}(X, \mathfrak{T})$, as claimed.

4A3I Corollary If $(X, \mathfrak{T})$ is a Polish space and $\langle E_n \rangle_{n \in \mathbb{N}}$ is a sequence of Borel subsets of X, then there is a Polish topology $\mathfrak{T}'$ on X, including $\mathfrak{T}$, for which every E_n is open-and-closed.

proof For each $n \in \mathbb{N}$ we can find a Polish topology $\mathfrak{T}_n \supseteq \mathfrak{T}$ containing E_k (if $n = 2k$ is even) or $X \setminus E_k$ (if $n = 2k+1$ is odd); now the topology $\mathfrak{T}'$ generated by $\bigcup_{n \in \mathbb{N}} \mathfrak{T}_n$ is Polish, by 4A2Qf, and every E_n is open-and-closed for $\mathfrak{T}'$.

4A3J Borel sets in ω_1: Proposition A set $E \subseteq \omega_1$ is a Borel set iff either E or its complement includes a closed cofinal set.

proof (a) Let Σ be the family of all those sets $E \subseteq \omega_1$ such that either E or $\omega_1 \setminus E$ includes a closed cofinal set. Of course Σ is closed under complements. Because the intersection of a sequence of closed cofinal sets is a closed cofinal set (4A1Bc), the union of any sequence in Σ belongs to Σ; so Σ is a σ-algebra. If E is closed, then either it is cofinal with ω_1, and is a closed cofinal set, or there is a $\xi < \omega_1$ such that $E \subseteq \xi$, in which case $\omega_1 \setminus E$ includes the closed cofinal set $\omega_1 \setminus \xi$; in either case, $E \in \Sigma$. Thus every open set belongs to Σ, and Σ includes $\mathcal{B}(\omega_1)$.

(b) Now suppose that $E \subseteq \omega_1$ is such that there is a closed cofinal set $F \subseteq \omega_1 \setminus E$. For each $\xi < \omega_1$ let $f_\xi : \xi \to \mathbb{N}$ be an injective function. Define $g : E \to \mathbb{N}$ by setting $g(\eta) = f_{\alpha(\eta)}(\eta)$, where $\alpha(\eta) = \min(F \setminus \eta)$ for $\eta \in E$. Set $A_n = g^{-1}[\{n\}]$ for $n \in \mathbb{N}$, so that $E = \bigcup_{n \in \mathbb{N}} A_n$. If $\xi \in \overline{A}_n \setminus A_n$ and $\xi' < \xi$, there must be η, $\eta' \in A_n$ such that $\xi' \leq \eta < \eta' < \xi$. But now, because $f_{\alpha(\eta')}$ is injective, while $g(\eta) = g(\eta') = n$, $\alpha(\eta) < \alpha(\eta')$, so $\alpha(\eta) \in F \cap]\xi', \xi[$. As ξ' is arbitrary, $\xi \in \overline{F} = F$. This shows that $\overline{A}_n \subseteq A_n \cup F$ and $A_n = \overline{A}_n \setminus F$ is a Borel set. This is true for every $n \in \mathbb{N}$, so $E = \bigcup_{n \in \mathbb{N}} A_n$ is a Borel set.

(c) If $E \subseteq \omega_1$ includes a closed cofinal set, then (b) tells us that $\omega_1 \setminus E$ and E belong to Σ. Thus $\Sigma \subseteq \mathcal{B}(\omega_1)$ and $\Sigma = \mathcal{B}(\omega_1)$, as claimed.

4A3K Baire sets When we come to study measures in terms of the integrals of continuous functions (§436), we find that it is sometimes inconvenient or even impossible to apply them to arbitrary Borel sets, and we need to use a smaller σ-algebra, as follows.

(a) Definition Let X be a topological space. The **Baire σ-algebra** $\mathcal{Ba}(X)$ of X is the σ-algebra generated by the zero sets. Members of $\mathcal{Ba}(X)$ are called **Baire** sets. (**Warning!** Do not confuse 'Baire sets' in this sense with 'sets with the Baire property' in the sense of 4A3Q, nor with 'sets which are Baire spaces in their subspace topologies'.)

(b) For any topological space X, $\mathcal{Ba}(X) \subseteq \mathcal{B}(X)$ (because every zero set is closed, therefore Borel). If $\mathfrak{T}$ is perfectly normal – for instance, if it is metrizable (4A2Lc), or is regular and hereditarily Lindelöf (4A2H(c-iii)) – then $\mathcal{Ba}(X) = \mathcal{B}(X)$ (because every closed set is a zero set, by 4A2Fi, so every open set belongs to $\mathcal{Ba}(X)$).

(c) Let X and Y be topological spaces, with Baire σ-algebras $\mathcal{Ba}(X)$, $\mathcal{Ba}(Y)$ respectively. If $f : X \to Y$ is continuous, it is $(\mathcal{Ba}(X), \mathcal{Ba}(Y))$-measurable. **P** Let T be the σ-algebra $\{F : F \subseteq Y, f^{-1}[F] \in \mathcal{Ba}(X)\}$. If $g : Y \to \mathbb{R}$ is continuous, then $gf : X \to \mathbb{R}$ is continuous, so

$$f^{-1}[\{y : g(y) = 0\}] = \{x : gf(x) = 0\} \in \mathcal{Ba}(X),$$

and $\{y : g(y) = 0\} \in \mathrm{T}$. Thus every zero set belongs to T, and $\mathrm{T} \supseteq \mathcal{Ba}(Y)$. **Q**

(d) In particular, if X is a subspace of Y, then $E \cap X \in \mathcal{Ba}(X)$ whenever $E \in \mathcal{Ba}(Y)$. More fundamentally, $F \cap X$ is a zero set in X for every zero set $F \subseteq Y$, just because $g \restriction X$ is continuous for any continuous $g : Y \to \mathbb{R}$.

(e) If X is a topological space and Y is a separable metrizable space, a function $f : X \to Y$ is **Baire measurable** if $f^{-1}[H] \in \mathcal{Ba}(X)$ for every open $H \subseteq Y$. Observe that f is Baire measurable in this sense iff it is $(\mathcal{Ba}(X), \mathcal{B}(Y))$-measurable iff it is $(\mathcal{Ba}(X), \mathcal{Ba}(Y))$-measurable.

4A3L Lemma Let $(X, \mathfrak{T})$ be a topological space. Then $\mathcal{Ba}(X)$ is just the smallest σ-algebra of subsets of X with respect to which every continuous real-valued function on X is measurable.

proof (a) Let $f : X \to \mathbb{R}$ be a continuous function and $\alpha \in \mathbb{R}$. Set $g(x) = \max(0, f(x) - \alpha)$ for $x \in X$; then g is continuous, so

$$\{x : f(x) \leq \alpha\} = \{x : g(x) = 0\}$$

is a zero set and belongs to $\mathcal{Ba}(X)$. As α is arbitrary, f is $\mathcal{Ba}(X)$-measurable.

(b) On the other hand, if Σ is any σ-algebra of subsets of X such that every continuous real-valued function on X is Σ-measurable, and $F \subseteq X$ is a zero set, then there is a continuous g such that $F = g^{-1}[\{0\}]$, so that $F \in \Sigma$; as F is arbitrary, $\Sigma \supseteq \mathcal{Ba}(X)$.

4A3M Product spaces Let $\langle X_i \rangle_{i \in I}$ be a family of topological spaces with product X.

(a) $\mathcal{Ba}(X) \supseteq \widehat{\bigotimes}_{i \in I} \mathcal{Ba}(X_i)$. (Apply 4A3Bc to the identity map from X to itself; compare 4A3Cf.)

(b) Suppose that X is ccc. Then every Baire subset of X is determined by coordinates in a countable set. **P** By 254Mb, the family $\mathcal{W}$ of sets determined by coordinates in countable sets is a σ-algebra of subsets of X. By 4A2E(b-ii), every continuous real-valued function is $\mathcal{W}$-measurable, so $\mathcal{W}$ contains every zero set and every Baire set. **Q**

4A3N Products of separable metrizable spaces: Proposition Let $\langle X_i \rangle_{i \in I}$ be a family of separable metrizable spaces, with product X.

(a) $\mathcal{Ba}(X) = \widehat{\bigotimes}_{i \in I} \mathcal{Ba}(X_i) = \widehat{\bigotimes}_{i \in I} \mathcal{B}(X_i)$.

(b) $\mathcal{Ba}(X)$ is the family of Borel subsets of X which are determined by coordinates in countable sets.

(c) A set $Z \subseteq X$ is a zero set iff it is closed and determined by coordinates in a countable set.

(d) If Y is a dense subset of X, then the Baire σ-algebra $\mathcal{Ba}(Y)$ of Y is just the subspace σ-algebra $\mathcal{Ba}(X)_Y$ induced by $\mathcal{Ba}(X)$.

(e) If Y is a set, T is a σ-algebra of subsets of Y, and $f : Y \to X$ is a function, then f is $(\mathrm{T}, \mathcal{Ba}(X))$-measurable iff $\pi_i f : Y \to X_i$ is $(\mathrm{T}, \mathcal{B}(X_i))$-measurable for every $i \in I$, where $\pi_i(x) = x(i)$ for $x \in X$, $i \in I$.

proof (a) X is ccc (4A2E(a-iii)), so if $f : X \to \mathbb{R}$ is continuous, there are a countable set $J \subseteq I$ and a continuous function $g : X_J \to \mathbb{R}$ such that $f = g\tilde{\pi}_J$, where $X_J = \prod_{i\in J} X_J$ and $\tilde{\pi}_J : X \to X_J$ is the canonical map (4A2E(b-ii)). Now X_J is separable and metrizable (4A2P(a-v)), therefore hereditarily Lindelöf (4A2P(a-iii)), so $\mathcal{B}(X_J) = \widehat{\bigotimes}_{i\in J}\mathcal{B}(X_i)$, by 4A3D(c-i). By 4A3Bc, $\tilde{\pi}_J$ is $(\widehat{\bigotimes}_{i\in I}\mathcal{B}(X_i), \widehat{\bigotimes}_{i\in J}\mathcal{B}(X_j))$-measurable, so f is $\widehat{\bigotimes}_{i\in J}\mathcal{B}(X_j)$-measurable. As f is arbitrary, $\mathcal{Ba}(X) \subseteq \widehat{\bigotimes}_{i\in I}\mathcal{B}(X_i)$ (4A3L). Also $\mathcal{B}(X_i) = \mathcal{Ba}(X_i)$ for every i (4A3Kb), so $\widehat{\bigotimes}_{i\in I}\mathcal{B}(X_i) = \widehat{\bigotimes}_{i\in I}\mathcal{Ba}(X_i)$. With 4A3Ma, this proves the result.

(b)(i) If $W \in \mathcal{Ba}(X)$ it is certainly a Borel set (4A3Kb), and by 4A3Mb it is determined by coordinates in a countable set.

(ii) If W is a Borel subset of X determined by coordinates in a countable subset J of X, then write $X_J = \prod_{i\in J} X_i$ and $X_{I\setminus J} = \prod_{i\in I\setminus J} X_i$; let $\tilde{\pi}_J : X \to X_J$ be the canonical map. We can identify W with $W' \times X_{I\setminus J}$, where W' is some subset of X_J. Now if $z \in X_{I\setminus J}$, $W' = \{w : w \in X_J, (w, z) \in W\}$ is a Borel subset of X_J, because $w \mapsto (w, z) : X_J \to X$ is continuous. (I am passing over the trivial case $X = \emptyset$.) Since X_J is metrizable (4A2P(a-v)), $W' \in \mathcal{Ba}(X_J)$ (4A3Kb) and $W = \tilde{\pi}_J^{-1}[W']$ is a Baire set (4A3Kc).

(c)(i) If Z is a zero set, it is surely closed; and it is determined by coordinates in a countable set by (b) above, or directly from 4A2E(b-ii).

(ii) If Z is closed and determined by coordinates in a countable set J, then (in the language of (b) above) it can be identified with $Z' \times X_{I\setminus J}$ for some $Z' \subseteq X_J$. As in the proof of (b), Z' is closed (at least, if $X_{I\setminus J} \neq \emptyset$), so is a zero set (4A2Lc), and $Z = \tilde{\pi}_J^{-1}[Z']$ is a zero set (4A2C(b-iv)).

(d)(i) $\mathcal{Ba}(Y) \supseteq \mathcal{Ba}(X)_Y$ by 4A3Kd.

(ii) Let $f : Y \to \mathbb{R}$ be any continuous function. For each $n \in \mathbb{N}$, there is an open set $G_n \subseteq X$ such that $G_n \cap Y = \{y : f(y) > 2^{-n}\}$. Now $\overline{G}_n$ is determined by coordinates in a countable set (4A2E(b-i)), so is a zero set, by (c) here. Because Y is dense in X, $\overline{G}_n = \overline{G_n \cap Y}$ does not meet $\{y : f(y) = 0\}$, and $\{y : f(y) > 0\} = Y \cap \bigcup_{n\in\mathbb{N}} \overline{G}_n$ belongs to $\mathcal{Ba}(X)_Y$. Thus $\mathcal{Ba}(X)_Y$ contains every cozero subset of Y and includes $\mathcal{Ba}(Y)$.

(e) Put (a) and 4A3Bc together.

4A3O Compact spaces (a) Let $(X, \mathfrak{T})$ be a topological space, $\mathcal{U}$ a subbase for $\mathfrak{T}$, and $\mathfrak{A}$ the algebra of subsets of X generated by $\mathcal{U}$. If $H \subseteq X$ is open and $K \subseteq H$ is compact, there is an $E \in \mathfrak{A}$ such that $K \subseteq E \subseteq H$. **P** Set $\mathcal{V} = \{X\} \cup \{U_0 \cap U_1 \cap \ldots \cap U_n : U_0, \ldots, U_n \in \mathcal{U}\}$, so that $\mathcal{V}$ is a base for $\mathfrak{T}$ and $\mathcal{V} \subseteq \mathfrak{A}$. $\{U : U \in \mathcal{V}, U \subseteq H\}$ is an open cover of the compact set K, so there is a finite set $\mathcal{U}_0 \subseteq \mathcal{V}$ such that $E = \bigcup \mathcal{U}_0$ includes K and is included in H; now $E \in \mathfrak{A}$. **Q**

(b) Let $(X, \mathfrak{T})$ be a compact space and $\mathcal{U}$ a subbase for $\mathfrak{T}$. Then every open-and-closed subset of X belongs to the algebra of subsets of X generated by $\mathcal{U}$. (If $F \subseteq X$ is open-and-closed, it is also compact; apply (a) here with $K = H = F$.)

(c) Let $(X, \mathfrak{T})$ be a compact space and $\mathcal{U}$ a subbase for $\mathfrak{T}$. Then $\mathcal{Ba}(X)$ is included in the σ-algebra of subsets of X generated by $\mathcal{U}$. **P** Let Σ be the σ-algebra generated by $\mathcal{U}$. If $Z \subseteq X$ is a zero set, there is a sequence $\langle H_n\rangle_{n\in\mathbb{N}}$ of open sets with intersection Z (4A2C(b-vi)); now we can find a sequence $\langle E_n\rangle_{n\in\mathbb{N}}$ in Σ such that $Z \subseteq E_n \subseteq H_n$ for every n, by (a), so that $Z = \bigcap_{n\in\mathbb{N}} E_n \in \Sigma$. This shows that every zero set belongs to Σ, so Σ must include $\mathcal{Ba}(X)$. **Q**

(d) If $\langle X_i\rangle_{i\in I}$ is a family of compact Hausdorff spaces with product X, then $\mathcal{Ba}(X) = \widehat{\bigotimes}_{i\in I}\mathcal{Ba}(X_i)$. **P** By 4A3Ma, $\mathcal{Ba}(X) \supseteq \widehat{\bigotimes}_{i\in I}\mathcal{Ba}(X_i)$. On the other hand, let $\mathcal{U}_i$ be the family of cozero sets in X_i for each i. Because X_i is completely regular (3A3Bb), $\mathcal{U}_i$ is a base for its topology (4A2Fc). Set

$$\mathcal{W} = \{\textstyle\prod_{i\in I} U_i : U_i \in \mathcal{U}_i \text{ for every } i \in I, \{i : U_i \neq X_i\} \text{ is finite}\},$$

so that $\mathcal{W} \subseteq \widehat{\bigotimes}_{i\in I}\mathcal{Ba}(X_i)$ is a base for the topology of X. By (c) above, $\mathcal{Ba}(X)$ is the σ-algebra generated by $\mathcal{W}$, and $\mathcal{Ba}(X) \subseteq \widehat{\bigotimes}_{i\in I}\mathcal{Ba}(X_i)$. **Q**

(e) In a compact Hausdorff zero-dimensional space the Baire σ-algebra is the σ-algebra generated by the open-and-closed sets. (Apply (c) with $\mathcal{U}$ the family of open-and-closed sets.)

(f) In particular, for any set I, $\mathcal{Ba}(\{0,1\}^I)$ is the σ-algebra generated by sets of the form $\{x : x(i) = 1\}$ as i runs over I.

4A3P Proposition The Baire σ-algebra $\mathcal{Ba}(\omega_1)$ of ω_1 is just the countable-cocountable algebra (211R).

proof We see from 4A2S(b-iii) that every continuous function is measurable with respect to the countable-cocountable algebra, so $\mathcal{Ba}(\omega_1)$ is included in the countable-cocountable algebra. On the other hand,

$$[0,\xi] = \{\eta : \eta \leq \xi\} = [0,\xi+1[= \omega_1 \setminus]\xi,\omega_1[$$

is an open-and-closed set (4A2S(a-i)), therefore a zero set, therefore belongs to $\mathcal{Ba}(\omega_1)$, for every $\xi < \omega_1$. Now if $\xi < \omega_1$, it is itself a countable set, so

$$[0,\xi[= \textstyle\bigcup_{\eta<\xi}[0,\eta] \in \mathcal{Ba}(\omega_1), \quad \{\xi\} = [0,\xi] \setminus [0,\xi[\in \mathcal{Ba}(\omega_1).$$

It follows that every countable set belongs to $\mathcal{Ba}(\omega_1)$ and the countable-cocountable algebra is included in $\mathcal{Ba}(\omega_1)$.

4A3Q Baire property If X is a topological space, a subset X has the **Baire property** if it is expressible in the form $G \triangle M$ where $G \subseteq X$ is open and $M \subseteq X$ is meager; that is, $A \subseteq X$ has the Baire property if there is an open set $G \subseteq X$ such that $G \triangle A$ is meager. (For $A = G \triangle M$ iff $M = G \triangle A$.) The family $\widehat{\mathcal{B}}(X)$ of all such sets is the **Baire property algebra** of X. (See 4A3R.) (**Warning!** do not confuse the 'Baire property algebra' $\widehat{\mathcal{B}}$ with the 'Baire σ-algebra' $\mathcal{Ba}$ as defined in 4A3K.)

4A3R Proposition Let X be a topological space.

(a) Let $A \subseteq X$ be any set.

(i) There is a unique regular open set $H \subseteq X$ such that $A \setminus H$ is meager and $H \cap G$ is empty whenever $G \subseteq X$ is open and $A \cap G$ is meager.

(ii) H is in itself a Baire space.

(iii) If A has the Baire property, $H \triangle A$ is meager.

(iv) If $A = X$, then H is the smallest comeager regular open set in X.

(b) $\widehat{\mathcal{B}}(X)$ is a σ-algebra of subsets of X including $\mathcal{B}(X)$.

(c) Write $\mathcal{M}$ for the family of meager subsets of X, so that $\mathcal{M}$ is a σ-ideal of $\widehat{\mathcal{B}}$. If X has a countable network, then the quotient algebra $\widehat{\mathcal{B}}/\mathcal{M}$ has a countable order-dense set (definition: 313J).

proof (a) (See Kechris 95, 8.29.)

(i) Set $\mathcal{G} = \{G : G \subseteq X \text{ is open, } A \cap G \text{ is meager}\}$. Let $\mathcal{G}_0 \subseteq \bigcup \mathcal{G}$ be a maximal disjoint set, and $G_0 = \bigcup \mathcal{G}_0$. Then $A \cap G_0$ is meager. **P** For each $G \in \mathcal{G}_0$, let $\langle F_{Gn}\rangle_{n\in\mathbb{N}}$ be a sequence of nowhere dense closed sets covering $A \cap G$. Set $A_n = \bigcup_{G\in\mathcal{G}_0} G \cap F_{Gn}$. If $U \subseteq X$ is any non-empty open set, either $U \cap A_n$ is empty or there is a $G \in \mathcal{G}_0$ such that $U \cap G \neq \emptyset$, in which case $U \cap G \setminus F_{Gn}$ is a non-empty open subset of U not meeting A_n. Thus A_n is nowhere dense. This is true for every n, so $A \cap G_0 \subseteq \bigcup_{n\in\mathbb{N}} A_n$ is meager. **Q**

Set $H = \operatorname{int}(X \setminus G_0)$, so that H is a regular open set (definition: 314O). $A \setminus H \subseteq (\overline{G}_0 \setminus G_0) \cup (A \cap G_0)$ is meager. If $G \in \mathcal{G}$ then $G \cap H = G \setminus \overline{G}_0$ belongs to $\mathcal{G}$ and is disjoint from every member of $\mathcal{G}_0$; by the maximality of $\mathcal{G}_0$, it is empty.

If $H' \neq H$ is another regular open set, either $H \setminus \overline{H'}$ is not empty and $A \setminus H' \supseteq A \cap H \setminus \overline{H'}$ is non-meager, or $H' \setminus \overline{H}$ is not empty and meets A in a meager set; so H is the only regular open set with the declared properties.

(ii) If now $\langle H_n\rangle_{n\in\mathbb{N}}$ is a sequence of open subsets of H which are dense in H, and $H' \subseteq H$ is any non-empty open set, $H' \setminus H_n$ is nowhere dense for every n, so $H' \setminus \bigcap_{n\in\mathbb{N}} H_n$ is meager. On the other hand, $A \cap H'$ is non-meager so H' also is, and H' must meet $\bigcap_{n\in\mathbb{N}} H_n$. As H' is arbitrary, $\bigcap_{n\in\mathbb{N}} H_n$ is dense in H; as $\langle H_n\rangle_{n\in\mathbb{N}}$ is arbitrary, H is a Baire space in its subspace topology.

(iii) If A has the Baire property, there is an open set G such that $A \triangle G$ is meager. In this case, $A \cap H \setminus \overline{G}$ must be meager, so $H \subseteq \overline{G}$ and $H \setminus A \subseteq (G \setminus A) \cup (\overline{G} \setminus G)$ is meager and $H \triangle A = (A \setminus H) \cup (H \setminus A)$ is meager.

(iv) If $A = X$, then H is comeager and is disjoint from every meager open set. So any comeager regular open set has complement disjoint from H and includes H; H is the smallest such set.

(b) (See Čech 66, §22C; Kuratowski 66, §11.III; Kechris 95, 8.22.) Of course $X = X \triangle \emptyset$ belongs to $\widehat{\mathcal{B}}(X)$. If $E \in \widehat{\mathcal{B}}(X)$, let $G \subseteq X$ be an open set such that $E \triangle G$ is meager. Then

$$(X \setminus \overline{G}) \triangle (X \setminus E) \subseteq (\overline{G} \setminus G) \cup (G \triangle E)$$

is meager, so $X \setminus E \in \widehat{\mathcal{B}}(X)$. If $\langle E_n \rangle_{n \in \mathbb{N}}$ is a sequence in $\widehat{\mathcal{B}}(X)$, then for each $n \in \mathbb{N}$ we can find an open set G_n such that $G_n \triangle E_n$ is meager, and now

$$(\bigcup_{n \in \mathbb{N}} G_n) \triangle (\bigcup_{n \in \mathbb{N}} E_n) \subseteq \bigcup_{n \in \mathbb{N}} G_n \triangle E_n$$

is meager, so $\bigcup_{n \in \mathbb{N}} E_n \in \widehat{\mathcal{B}}(X)$.

This shows that $\widehat{\mathcal{B}}(X)$ is a σ-algebra of subsets of X. Since it contains every open set, it must include the Borel σ-algebra.

(c) Suppose that X has a countable network $\mathcal{A}$. For $A \in \mathcal{A}$, set $d_A = \overline{A}^\bullet$, the equivalence class of $\overline{A} \in \widehat{\mathcal{B}}$ in $\widehat{\mathcal{B}}/\mathcal{M}$. If $b \in \widehat{\mathcal{B}}/\mathcal{M}$ is non-zero, take $E \in \widehat{\mathcal{B}}$ such that $E^\bullet = b$, and an open set $G \subseteq X$ such that $E \triangle G \in \mathcal{M}$. Then G is not meager. Set $\mathcal{A}_1 = \{A : A \in \mathcal{A}, A \subseteq G\}$; then $\mathcal{A}_1$ is countable and $G = \bigcup \mathcal{A}_1$, so there is a non-meager $A \in \mathcal{A}_1$. In this case $\overline{A}$ is not meager, so $d_A \neq 0$, while $\overline{A} \setminus G \subseteq \overline{G} \setminus G$ is nowhere dense, so $d_A \subseteq b$. As b is arbitrary, $\{d_A : A \in \mathcal{A}\}$ is order-dense in $\widehat{\mathcal{B}}/\mathcal{M}$, and is countable because $\mathcal{A}$ is.

***4A3S** The following result will be useful in §424 and in Volume 5.

Lemma Let X and Y be sets, Σ a σ-algebra of subsets of X, T a σ-algebra of subsets of Y and $\mathcal{J}$ a σ-ideal of T. Suppose that the quotient Boolean algebra $\mathrm{T}/\mathcal{J}$ has a countable order-dense set.

(a) $\{x : x \in X, W[\{x\}] \cap A \in \mathcal{J}\}$ belongs to Σ for any $W \in \Sigma \widehat{\otimes} \mathrm{T}$ and $A \subseteq Y$.

(b) For every $W \in \Sigma \widehat{\otimes} \mathrm{T}$ there are sequences $\langle E_n \rangle_{n \in \mathbb{N}}$ in Σ, $\langle V_n \rangle_{n \in \mathbb{N}}$ in T such that $(W \triangle W_1)[\{x\}] \in \mathcal{J}$ for every $x \in X$, where $W_1 = \bigcup_{n \in \mathbb{N}} E_n \times V_n$.

proof (Compare Kechris 95, 16.1.)

(a) Let $D \subseteq \mathrm{T}/\mathcal{J}$ be a countable order-dense set. Let $\mathcal{V} \subseteq \mathrm{T}$ be a countable set such that $D = \{V^\bullet : V \in \mathcal{V}\}$. Let Λ be the family of subsets W of $X \times Y$ such that

$$W[\{x\}] \in \mathrm{T} \text{ for every } x \in X,$$

$$\{x : x \in X, W[\{x\}] \cap A \in \mathcal{J}\} \in \Sigma \text{ for every } A \subseteq Y.$$

(i) Of course $\emptyset \in \Lambda$, because if $W = \emptyset$ then $W[\{x\}] = \emptyset$ for every $x \in X$, and $\{x : W[\{x\}] \cap A \in \mathcal{J}\} = X$ for every $A \subseteq Y$.

(ii) Suppose that $W \in \Lambda$, and set $W' = (X \times Y) \setminus W$. Then

$$W'[\{x\}] = Y \setminus W[\{x\}] \in \mathrm{T}$$

for every $x \in X$. Now suppose that $A \subseteq Y$. Set $\mathcal{V}^* = \{V : V \in \mathcal{V}, A \cap V \notin \mathcal{J}\}$,

$$E = \{x : W'[\{x\}] \cap A \in \mathcal{J}\},$$

$$E' = \{x : V \cap W[\{x\}] \notin \mathcal{J} \text{ for every } V \in \mathcal{V}^*\}.$$

Then $E = E'$. **P** (α) If $x \in E$ and $V \in \mathcal{V}^*$, then $A \cap W'[\{x\}] = A \setminus W[\{x\}]$ belongs to $\mathcal{J}$, so $V \cap A \setminus W[\{x\}] \in \mathcal{J}$ and $V \cap W[\{x\}] \supseteq V \cap A \cap W[\{x\}]$ is not in $\mathcal{J}$. As V is arbitrary, $x \in E'$; as x is arbitrary, $E \subseteq E'$. (β) If $x \notin E$, then $W'[\{x\}] \cap A \notin \mathcal{J}$. Set $\mathcal{V}_1 = \{V : V \in \mathcal{V}, V \setminus W'[\{x\}] \in \mathcal{J}\}$, $D_1 = \{V^\bullet : V \in \mathcal{V}_1\}$. Then $D_1 = \{d : d \in D, d \subseteq W'[\{x\}]^\bullet\}$, so $W'[\{x\}]^\bullet = \sup D_1$ in $\mathrm{T}/\mathcal{J}$ (313K). Because $\mathcal{J}$ is a σ-ideal, the map $F \mapsto F^\bullet : \mathrm{T} \to \mathrm{T}/\mathcal{J}$ is sequentially order-continuous (313Qb), and $(\bigcup \mathcal{V}_1)^\bullet = \sup D_1$ (313Lc), that is,

$W'[\{x\}] \triangle \bigcup \mathcal{V}_1 \in \mathcal{J}$. There must therefore be a $V \in \mathcal{V}_1$ such that $V \cap A \notin \mathcal{J}$, that is, $V \in \mathcal{V}^*$. At the same time, $V \cap W[\{x\}] = V \setminus W'[\{x\}]$ belongs to $\mathcal{J}$, so V witnesses that $x \notin E'$. As x is arbitrary, $E' \subseteq E$. **Q**

Since $W \in \Lambda$,

$$E = E' = X \setminus \bigcup_{V \in \mathcal{V}^*} \{x : V \cap W[\{x\}] \in \mathcal{J}\}$$

belongs to T. As A is arbitrary, $W' \in \Lambda$. Thus the complement of any member of Λ belongs to Λ.

(iii) If $\langle W_n \rangle_{n \in \mathbb{N}}$ is any sequence in Λ with union W, then

$$W[\{x\}] = \bigcup_{n \in \mathbb{N}} W_n[\{x\}] \in \mathrm{T}$$

for every x, while

$$\{x : W[\{x\}] \cap A \in \mathcal{J}\} = \bigcap_{n \in \mathbb{N}} \{x : W_n[\{x\}] \cap A \in \mathcal{J}\} \in \Sigma$$

for every $A \subseteq Y$. So $W \in \Lambda$.

(iv) What this shows is that Λ is a σ-algebra of subsets of $X \times Y$. But if $W = E \times F$, where $E \in \Sigma$ and $F \in \mathrm{T}$, then

$$W[\{x\}] \in \{\emptyset, F\} \subseteq \mathrm{T} \text{ for every } x \in X,$$

$$\{x : W[\{x\}] \cap A \in \mathcal{J}\} \in \{X \setminus E, X\} \subseteq \Sigma$$

for every $A \subseteq Y$; so $W \in \Lambda$. Accordingly Λ must include $\Sigma \widehat{\otimes} \mathrm{T}$, as claimed.

(b) Let $\langle V_n \rangle_{n \in \mathbb{N}}$ be a sequence running over $\mathcal{V} \cup \{\emptyset\}$. For each $n \in \mathbb{N}$, set

$$E_n = \{x : V_n \setminus W[\{x\}] \in \mathcal{J}\};$$

by (a), $E_n \in \Sigma$. Set $W_1 = \bigcup_{n \in \mathbb{N}} E_n \times V_n$. Take any $x \in X$. Then $W_1[\{x\}] = \bigcup_{n \in I} V_n$ where $I = \{n : x \in E_n\}$. Since $V_n \setminus W[\{x\}] \in \mathcal{J}$ for every $n \in I$, $W_1[\{x\}] \setminus W[\{x\}] \in \mathcal{J}$. **?** If $W[\{x\}] \setminus W_1[\{x\}] \notin \mathcal{J}$, there is a $d \in D$ such that $0 \neq d \subseteq W[\{x\}]^\bullet \setminus W_1[\{x\}]^\bullet$. Let $n \in \mathbb{N}$ be such that $V_n^\bullet = d$; then $V_n \setminus W[\{x\}] \in \mathcal{J}$, so $n \in I$ and $V_n \subseteq W_1[\{x\}]$ and $d \subseteq W_1[\{x\}]^\bullet$, which is impossible. **X**

As x is arbitrary, W_1 has the required properties.

4A3T Cylindrical σ-algebras I end the section with a note on a particular type of Baire σ-algebra.

Definition Let X be a linear topological space. Then the **cylindrical σ-algebra** of X is the smallest σ-algebra Σ of subsets of X such that every continuous linear functional on X is Σ-measurable.

4A3U Proposition Let X be a linear topological space and $\mathfrak{T}_s = \mathfrak{T}_s(X, X^*)$ its weak topology. Then the cylindrical σ-algebra of X is just the Baire σ-algebra of $(X, \mathfrak{T}_s)$.

proof (a) Let $\langle f_i \rangle_{i \in I}$ be a Hamel basis for X^* (4A4Ab). For $x \in X$, set $Tx = \langle f_i(x) \rangle_{i \in I}$; then $T : X \to \mathbb{R}^I$ is a linear operator. Now $Y = T[X]$ is dense in $\mathbb{R}^I$. **P** Y is a linear subspace of $\mathbb{R}^I$, so its closure $\overline{Y}$ also is (2A5Ec). If $\phi \in (\mathbb{R}^I)^*$ is such that $\phi(Tx) = 0$ for every $x \in X$, there are a finite set $J \subseteq I$ and a family $\langle \alpha_i \rangle_{i \in J} \in \mathbb{R}^J$ such that $\phi(y) = \sum_{i \in J} \alpha_i y(i)$ for every $y \in \mathbb{R}^I$ (4A4Be). In this case, $\sum_{i \in J} \alpha_i f_i(x) = \phi(Tx) = 0$ for every $x \in X$; but $\langle f_i \rangle_{i \in I}$ is linearly independent, so $\alpha_i = 0$ for every $i \in J$ and $\phi = 0$. By 4A4Eb, $\overline{Y}$ must be the whole of $\mathbb{R}^I$. **Q**

(b)(i) Set $\mathfrak{T}'_s = \{T^{-1}[H] : H \subseteq Y \text{ is open}\}$. Then $\mathfrak{T}'_s = \mathfrak{T}_s$. **P** Because every f_i is continuous, T is continuous, so $\mathfrak{T}'_s \subseteq \mathfrak{T}_s$. On the other hand, any $f \in X^*$ is a linear combination of the f_i, so is $\mathfrak{T}'_s$-continuous, and $\mathfrak{T}_s \subseteq \mathfrak{T}'_s$. **Q**

(ii) If $g : X \to \mathbb{R}$ is $\mathfrak{T}_s$-continuous, there is a continuous $g_1 : Y \to \mathbb{R}$ such that $g = g_1 T$. **P** If $x, x' \in X$ are such that $Tx = Tx'$, then every $\mathfrak{T}_s$-open set containing one must contain the other, so $g(x) = g(x')$. This means that there is a function $g_1 : Y \to \mathbb{R}$ such that $g = g_1 T$. Next, if $U \subseteq \mathbb{R}$ is open, $T^{-1}[g_1^{-1}[U]] = g^{-1}[U]$ belongs to $\mathfrak{T}_s = \mathfrak{T}'_s$, so $g_1^{-1}[U]$ must be open in Y; as U is arbitrary, g_1 is continuous. **Q**

(c) Now let Σ be the cylindrical σ-algebra of X. Then every $f_i : X \to \mathbb{R}$ is Σ-measurable, so $T : X \to \mathbb{R}^I$ is $(\Sigma, \mathcal{B}\mathfrak{a}(\mathbb{R}^I))$-measurable, by 4A3Ne. Because Y is dense in $\mathbb{R}^I$, $\mathcal{B}\mathfrak{a}(Y)$ is the subspace σ-algebra induced by $\mathcal{B}\mathfrak{a}(\mathbb{R}^I)$ (4A3Nd). So $T : X \to Y$ is $(\Sigma, \mathcal{B}\mathfrak{a}(Y))$-measurable. Now if $g : X \to \mathbb{R}$ is a continuous function,

there is a continuous function $g_1 : Y \to \mathbb{R}$ such that $g = g_1 T$; g_1 is $\mathcal{Ba}(Y)$-measurable, so g is Σ-measurable. As this is true for every $\mathfrak{T}_s$-continuous $g : X \to \mathbb{R}$, $\mathcal{Ba}(X) \subseteq \Sigma$.

(d) On the other hand, $\Sigma \subseteq \mathcal{Ba}(X)$ just because every member of X^* is $\mathfrak{T}_s$-continuous. So $\Sigma = \mathcal{Ba}(X)$, as claimed.

4A3V Proposition Let $(X, \mathfrak{T})$ be a separable metrizable locally convex linear topological space, and $\mathfrak{T}_s = \mathfrak{T}_s(X, X^*)$ its weak topology. Then the cylindrical σ-algebra of X is also both the Baire σ-algebra and the Borel σ-algebra for both $\mathfrak{T}$ and $\mathfrak{T}_s$.

proof (a) For any linear topological space, we have

$$\Sigma \subseteq \mathcal{Ba}(X, \mathfrak{T}_s) \subseteq \mathcal{Ba}(X, \mathfrak{T}) \subseteq \mathcal{B}(X, \mathfrak{T}), \quad \mathcal{Ba}(X, \mathfrak{T}_s) \subseteq \mathcal{B}(X, \mathfrak{T}_s) \subseteq \mathcal{B}(X, \mathfrak{T}),$$

writing Σ for the cylindrical σ-algebra and $\mathcal{Ba}(X, \mathfrak{T}_s)$, $\mathcal{Ba}(X, \mathfrak{T})$, $\mathcal{B}(X, \mathfrak{T}_s)$ and $\mathcal{B}(X, \mathfrak{T})$ for the Baire and Borel σ-algebras of the two topologies. So all I have to do is to show that $\mathcal{B}(X, \mathfrak{T}) \subseteq \Sigma$.

Let $\langle \tau_n \rangle_{n \in \mathbb{N}}$ be a sequence of seminorms defining the topology of X (4A4Cf), and $D \subseteq X$ a countable dense set; for $n \in \mathbb{N}$, $\delta > 0$ and $x \in X$, set $U_n(x, \delta) = \{y : \tau_i(y - x) < \delta \text{ for every } i \leq n\}$. Then every $U_n(x, \delta)$ is a convex open set. Set

$$\mathcal{U} = \{U_n(z, 2^{-m}) : z \in D,\ m,\ n \in \mathbb{N}\}.$$

(b) If $G \subseteq X$ is any convex open set, $\overline{G} \in \Sigma$. **P** Set $\mathcal{U}_G = \{U : U \in \mathcal{U},\ U \cap G = \emptyset\}$. For each $U \in \mathcal{U}_G$, there are $f_U \in X^*$, $\alpha_U \in \mathbb{R}$ such that $f_U(x) < \alpha_U$ for every $x \in G$ and $f_U(x) > \alpha_U$ for every $x \in U$ (4A4Db). So $F = \{x : f_U(x) \leq \alpha_U \text{ for every } U \in \mathcal{U}_G\}$ belongs to Σ. Of course $F \supseteq \overline{G}$. On the other hand, if $x \notin \overline{G}$, there are m, $n \in \mathbb{N}$ such that $G \cap U_n(x, 2^{-m}) = \emptyset$; if we take $z \in D \cap U_n(x, 2^{-m-1})$, $U = U_n(z, 2^{-m-1})$ then $x \in U \in \mathcal{U}_G$, so $f_U(x) > \alpha_U$ and $x \notin F$. Thus $\overline{G} = F$ belongs to Σ. **Q**

(c) In particular, $\mathcal{V} = \{\overline{U} : U \in \mathcal{U}\}$ is included in Σ. But $\mathcal{V}$ is a countable network for $\mathfrak{T}$. So every member of $\mathfrak{T}$ is a union of countably many members of Σ and belongs to Σ. It follows at once that $\mathcal{B}(X, \mathfrak{T}) \subseteq \Sigma$, as required.

4A3X Basic exercises (a) (i) Let X be a regular space with a countable network and Y any topological space. Show that $\mathcal{B}(X \times Y) = \mathcal{B}(X) \widehat{\otimes} \mathcal{B}(Y)$. (*Hint*: 4A2Ng.) (ii) Set $X = [0, 1]$ with the topology generated by $\{X \setminus \{x\} : x \in X\}$ and $Y = [0, 1]$ with the discrete topology. Show that X has a countable network and that $\{(x, x) : x \in [0, 1]\}$ is a closed subset of $X \times Y$ not belonging to $\mathcal{B}(X) \times \mathcal{B}(Y)$.

(b) Let X be a topological space, and $E \subseteq X$. Show that the following are equiveridical: (i) $E \in \mathcal{Ba}(X)$; (ii) there are a continuous function $f : X \to [0, 1]^{\mathbb{N}}$ and $F \in \mathcal{B}([0, 1]^{\mathbb{N}})$ such that $E = f^{-1}[F]$; (iii) there are a metric space Z, a continuous function $f : X \to Z$ and an $F \in \mathcal{B}(Z)$ such that $E = f^{-1}[F]$.

>(c) Let X be a topological space, and $K \subseteq X$ a compact set such that $K \in \mathcal{Ba}(X)$. Show that K is a zero set. (*Hint*: 4A3Xb.)

(d) Let X be a compact Hausdorff space such that $\mathcal{Ba}(X) = \mathcal{B}(X)$. Show that X is perfectly normal.

(e) Let $\mathfrak{S}$ be the topology on $\mathbb{R}$ generated by the usual topology and $\{\{x\} : x \in \mathbb{R} \setminus \mathbb{Q}\}$. Show that $\mathfrak{S}$ is completely regular and Hausdorff and that $\mathbb{Q}$ is a closed Baire set which is not a zero set.

(f) Let $\langle X_i \rangle_{i \in I}$ be a family of spaces with countable networks, and X their product. Show that $\mathcal{Ba}(X) = \widehat{\bigotimes}_{i \in I} \mathcal{Ba}(X_i)$.

>(g) (i) Let I be an uncountable set with its discrete topology, and X the one-point compactification of I. Show that $\mathcal{Ba}(I)$ is not the subspace σ-algebra generated by $\mathcal{Ba}(X)$. (ii) Show that ω_1 has a subset I such that $\mathcal{Ba}(I)$ is not the subspace σ-algebra induced by $\mathcal{Ba}(\omega_1)$.

4A3Y Further exercises (a) Let X be a Čech-complete space and $\langle E_n \rangle_{n \in \mathbb{N}}$ a sequence of Borel sets in X. Show that there is a Čech-complete topology on X, finer than the given topology, with the same weight, and containing every E_n.

(b) Let $\langle X_i\rangle_{i\in I}$ be a family of regular spaces with countable networks, with product X. Show that (i) $\mathcal{B}\mathfrak{a}(X)$ is the family of Borel subsets of X which are determined by coordinates in countable sets; (ii) a set $Z \subseteq X$ is a zero set iff it is closed and determined by coordinates in a countable set; (iii) if $Y \subseteq X$ is dense, then $\mathcal{B}\mathfrak{a}(Y)$ is just the subspace σ-algebra $\mathcal{B}\mathfrak{a}(X)_Y$ induced by $\mathcal{B}\mathfrak{a}(X)$.

4A3 Notes and comments Much of this section consists of easy technicalities. It is however not always easy to guess at the exact results obtainable by these methods. It is important to notice that Baire σ-algebras on subspaces can give difficulties which do not arise with Borel σ-algebras (4A3Xg, 4A3Ca). I have expressed 4A3D in terms of 'hereditarily Lindelöf' spaces. Of course the separable metrizable spaces form by far the most important class of these, but there are others (the split interval, for instance) which are of great interest in measure theory. Similarly, there are important products of non-metrizable spaces which are ccc (e.g., 417Xu(vii)), so that 4A3Mb has something to say.

4A3H-4A3I are a most useful tool in studying Borel subsets of Polish spaces, especially in conjunction with the First Separation Theorem (422I); see 424G and 424H. I include 4A3Ya and 4A3Yb to show that some more of the arguments here can be adapted to non-separable or non-metrizable spaces.

You will note my caution in the definition of 'Baire measurable' function (4A3Ke). This is supposed to cover the case of functions taking values in $[-\infty, \infty]$ without taking a position on functions between general topological spaces.

4A4 Locally convex spaces

As in §3A5, all the ideas, and nearly all the results as stated below, are applicable to complex linear spaces; but for the purposes of this volume the real case will almost always be sufficient, and for definiteness you may take it that the scalar field is $\mathbb{R}$, except in 4A4J-4A4K. (Complex Hilbert spaces arise naturally in §445.)

4A4A Linear spaces (a) If U is a linear space, a **Hamel basis** for U is a maximal linearly independent family $\langle u_i\rangle_{i\in I}$ in U, so that every member of U is uniquely expressible as $\sum_{i\in J} \alpha_i u_i$ for some finite $J \subseteq I$, $\langle \alpha_i\rangle_{i\in J} \in (\mathbb{R} \setminus \{0\})^J$.

(b) Every linear space has a Hamel basis. (Schaefer 71, p. 10; Köthe 69, §7.3.)

(c) If U is a linear space, I write U' for the algebraic dual of U, the linear space of all linear functionals from U to $\mathbb{R}$.

4A4B Linear topological spaces (see §2A5) **(a)** If U is a linear topological space, and V is a linear subspace of U, then V, with the linear structure and topology induced by those of U, is again a linear topological space. (Bourbaki 87, I.1.3; Schaefer 71, §I.2; Köthe 69, §15.2.)

(b) If $\langle U_i\rangle_{i\in I}$ is any family of linear topological spaces, then $U = \prod_{i\in I} U_i$, with the product linear space structure and topology, is again a linear topological space. (Bourbaki 87, I.1.3; Schaefer 71, §I.2; Köthe 69, §15.4.) In particular, $\mathbb{R}^X$, with its usual linear and topological structures, is a linear topological space, for any set X.

(c) If U and V are linear topological spaces, the set of continuous linear operators from U to V is a linear subspace of the space $\mathrm{L}(U;V)$ of all linear operators from U to V. If U, V and W are linear topological spaces, and $T : U \to V$ and $S : V \to W$ are continuous linear operators, then $ST : U \to W$ is a continuous linear operator.

(d) If U is a linear topological space, I will write U^* for the **dual** of U, the space of all continuous linear functionals from U to $\mathbb{R}$ (compare 2A4H). U^* is a linear subspace of U' as defined in 4A4Ac. The **weak topology** on U, $\mathfrak{T}_s(U, U^*)$, is that defined by the method of 2A5B from the seminorms $u \mapsto |f(u)|$ as f runs through U^* (compare 2A5Ia). The **weak* topology** on U^*, $\mathfrak{T}_s(U^*, U)$, is that defined by the method of 2A5B from the seminorms $f \mapsto |f(u)|$ as u runs through U (compare 2A5Ig). By 2A5B, both are linear space topologies. If U and V are linear topological spaces, $T : U \to V$ is a continuous linear operator, and $g \in V^*$, then $gT \in U^*$ ((c) above).

(e) If $U = \prod_{i\in I} U_i$ is a product of linear topological spaces, then every element of U^* is of the form $u \mapsto \sum_{i\in J} f_i(u(i))$ where $J \subseteq I$ is finite and $f_i \in U_i^*$ for every $i \in J$. (Bourbaki 87, II.6.6; Schaefer 71, IV.4.3; Köthe 69, §22.5.)

(f) If U is a linear topological space, a set $A \subseteq U$ is **bounded** if for every neighbourhood G of 0 there is an $n \in \mathbb{N}$ such that $A \subseteq nG$. The closure of a bounded set is bounded. (Schaefer 71, I.5.1; Rudin 91, 1.13.)

(g) If U and V are linear topological spaces, $T : U \to V$ is a continuous linear operator and $A \subseteq U$ is a bounded set, then $T[A] \subseteq V$ is bounded. (Schaefer 71, I.5.4; Köthe 69, §15.6; Rudin 91, 1.32.)

(h) Let U be a linear topological space. If G is a neighbourhood of 0 in U, then its **polar** set in U^*, $G^\circ = \{f : f \in U^*, f(x) \leq 1 \text{ for every } x \in G\}$, is a $\mathfrak{T}_s(U^*, U)$-compact subset of U^* (compare 3A5F). (Schaefer 71, III.4.3; Köthe 69, §20.9; Rudin 91, 3.15.)

(i) Let U be a linear topological space. If $D \subseteq U$ is non-empty and closed under addition and multiplication by rationals, $\overline{D}$ is a linear subspace of U. **P** The linear span

$$V = \{\textstyle\sum_{i=0}^n \alpha_i u_i : u_0, \dots, u_n \in D, \alpha_0, \dots, \alpha_n \in \mathbb{R}\}$$

of

$$D = \{\textstyle\sum_{i=0}^n \alpha_i u_i : u_0, \dots, u_n \in D, \alpha_0, \dots, \alpha_n \in \mathbb{Q}\}$$

is included in $\overline{D}$, because addition and scalar multiplication are continuous; so $\overline{D} = \overline{V}$ is a linear subspace. **Q** If $A \subseteq U$ is separable, then the closed linear subspace generated by A is separable. **P** let $D_0 \subseteq A$ be a countable dense subset; then

$$D = \{\textstyle\sum_{i=0}^n \alpha_i u_i : u_0, \dots, u_n \in D_0, \alpha_0, \dots, \alpha_n \in \mathbb{Q}\}$$

is countable, and $\overline{D}$ is separable; but $\overline{D}$ is the closed linear subspace generated by A. **Q**

(j) If $\langle u_i\rangle_{i\in I}$ is an indexed family in a Hausdorff linear topological space U and $u \in U$, we say that $u = \sum_{i\in I} u_i$ if for every neighbourhood G of u there is a finite set $J \subseteq I$ such that $\sum_{i\in K} u_i \in G$ whenever $K \subseteq I$ is finite and $J \subseteq K$ (compare 226Ad).

If now V is another Hausdorff linear topological space and $T : U \to V$ is a continuous linear operator, $\sum_{i\in I} Tu_i = T(\sum_{i\in I} u_i)$ if the right-hand-side is defined. **P** Set $u = \sum_{i\in I} u_i$. If H is an open set containing Tu, then $T^{-1}[H]$ is an open set containing u, so there is a $J \in [I]^{<\omega}$ (notation: 3A1J) such that $\sum_{i\in K} u_i \in T^{-1}[H]$ and $\sum_{i\in K} Tu_i \in H$ whenever $J \subseteq K \in [I]^{<\omega}$. **Q**

(k) If U is a Hausdorff linear topological space, then any finite-dimensional linear subspace of U is closed. (Schaefer 71I.3.3; Taylor 64, 3.12-C; Rudin 91, 1.2.1.)

4A4C Locally convex spaces (a) A linear topological space U (2A5A) is **locally convex** if the convex open sets form a base for the topology.

(b) A linear topological space is locally convex iff its topology can be defined by a family of seminorms (2A5B, 2A5D). (Bourbaki 87, II.4.1; Schaefer 71, §II.4; Köthe 69, §18.1.)

(c) Let U be a linear space and τ a seminorm on U. Then $N_\tau = \{u : \tau(u) = 0\}$ is a linear subspace of X. On the quotient space U/N_τ we have a norm defined by setting $\|u^\bullet\| = \tau(u)$ for every $u \in U$. (Bourbaki 87, II.1.3; Schaefer 71, II.5.4; Rudin 91, 1.43.)

(d) Let U be a locally convex linear topological space, and T the family of continuous seminorms on U. For each $\tau \in \mathrm{T}$, write $N_\tau = \{u : \tau(u) = 0\}$, as in (c) above, and π_τ for the canonical map from U to $U_\tau = U/N_\tau$. Give each U_τ its norm, and set $\mathcal{G}_\tau = \{\pi_\tau^{-1}[H] : H \subseteq U_\tau \text{ is open}\}$. Then $\bigcup_{\tau\in\mathrm{T}} \mathcal{G}_\tau$ is a base for the topology of X closed under finite unions. (Schaefer 71, II.5.4.)

(e) A linear subspace of a locally convex linear topological space is locally convex. (Bourbaki 87, II.4.3; Köthe 69, §18.3.) The product of any family of locally convex linear topological spaces (4A4Bb) is locally convex. (Bourbaki 87, II.4.3; Köthe 69, §18.3.)

(f) If U is a metrizable locally convex linear topological space, its topology can be defined by a sequence of seminorms. (Bourbaki 87, II.4.1; Köthe 69, §18.2.)

(g) Let U be a linear space and V a linear subspace of the space U' of all linear functionals on U. Let $\mathfrak{T}_s(V,U)$ be the topology on V generated by the seminorms $f \mapsto |f(u)|$ as u runs over U (compare 4A4Bd), and let $\phi : V \to \mathbb{R}$ be a $\mathfrak{T}_s(V,U)$-continuous linear functional. Then there is a $u \in U$ such that $\phi(f) = f(u)$ for every $f \in V$. (Bourbaki 87, IV.1.1; Schaefer 71, IV.1.2; Köthe 69, §20.2; Rudin 91, 3.10; Dunford & Schwartz 57, II.3.9; Taylor 64, 3.81-A.)

(h) Grothendieck's theorem If U is a complete locally convex Hausdorff linear topological space, and ϕ is a linear functional on the dual U^* such that $\phi \restriction G^\circ$ is $\mathfrak{T}_s(U^*,U)$-continuous for every neighbourhood G of 0 in U (defining G° as in 4A4Bh), then ϕ is of the form $f \mapsto f(u)$ for some $u \in U$. (Bourbaki 87, III.3.6; Schaefer 71, IV.6.2; Köthe 69, §21.9.)

4A4D Hahn-Banach theorem (a) Let U be a linear space and $\theta : U \to [0,\infty[$ a seminorm.

(i) If $V \subseteq U$ is a linear subspace and $g : V \to \mathbb{R}$ is a linear functional such that $|g(v)| \leq \theta(v)$ for every $v \in V$, then there is a linear functional $f : U \to \mathbb{R}$, extending g, such that $|f(u)| \leq \theta(u)$ for every $u \in U$.

(ii) If $u_0 \in U$ then there is a linear functional $f : U \to \mathbb{R}$ such that $f(u_0) = \theta(u_0)$ and $|f(u)| \leq \theta(u)$ for every $u \in U$. (Bourbaki 87, II.3.2; Rudin 91, 3.3; Dunford & Schwartz 57, II.3.11; Taylor 64, 3.7-C.)

(b) Let U be a linear topological space and G, H two disjoint convex sets in U, of which one has non-empty interior. Then there are an $f \in U^*$ and an $\alpha \in \mathbb{R}$ such that $f(u) \leq \alpha \leq f(v)$ for every $u \in G$, $v \in H$. If G and H are both open, then $f(u) < \alpha < f(v)$ for every $u \in G$, $v \in H$. (Bourbaki 87, II.5.2; Schaefer 71, II.9.1; Köthe 69, §17.1.)

4A4E The Hahn-Banach theorem in locally convex spaces Let U be a locally convex linear topological space.

(a) If $V \subseteq U$ is a linear subspace, then every member of V^* extends to a member of U^* (compare 3A5Ab). (Bourbaki 87, II.4.1; Schaefer 71, II.4.2; Köthe 69, §20.1; Rudin 91, 3.6; Taylor 64, 3.8-D.)

Consequently $\mathfrak{T}_s(V,V^*)$ is just the subspace topology on V induced by $\mathfrak{T}_s(U,U^*)$.

(b) Let $C \subseteq U$ be a non-empty closed convex set. If $u \in U$ then $u \in C$ iff $f(u) \leq \sup_{v\in C} f(v)$ for every $f \in U^*$ iff $f(u) \geq \inf_{v\in C} f(v)$ for every $f \in U^*$. (Bourbaki 87, II.5.3; Schaefer 71, II.9.2; Köthe 69, §20.7; Dunford & Schwartz 57, V.2.12.)

If $V \subseteq U$ is a closed linear subspace and $u \in U \setminus V$ there is an $f \in U^*$ such that $f(u) \neq 0$ and $f(v) = 0$ for every $v \in V$. (Bourbaki 87, II.5.3; Köthe 69, §20.1; Rudin 91, 3.5; Taylor 64, 3.8-E.)

(c) If U is Hausdorff, U^* separates its points (compare 3A5Ae). (Bourbaki 87, II.4.1; Rudin 91, 3.4.)

(d) If $u \in U$ belongs to the $\mathfrak{T}_s(U,U^*)$-closure of a convex set $C \subseteq U$, it belongs to the closure of C (compare 3A5Ee). (Schaefer 71, II.9.2; Köthe 69, §20.7; Rudin 91, 3.12.) In particular, if C is closed, it is $\mathfrak{T}_s(U,U^*)$-closed. (Dunford & Schwartz 57, V.2.13.)

(e) If C, $C' \subseteq U$ are disjoint non-empty closed convex sets, of which one is compact, there is an $f \in U^*$ such that $\sup_{u\in C} f(u) < \inf_{u\in C'} f(u)$. (Apply (b) to $C - C'$. See Bourbaki 87, II.5.3; Schaefer 71, II.9.2; Köthe 69, §20.7; Rudin 91, 3.4; Dunford & Schwartz 57, V.3.13.)

(f) Let V be a linear subspace of U'. Let $K \subseteq U$ be a non-empty $\mathfrak{T}_s(U,V)$-compact convex set, and $\phi_0 : V \to \mathbb{R}$ a linear functional such that $\phi_0(f) \leq \sup_{u\in K} f(u)$ for every $f \in V$. Then there is a $u_0 \in K$ such that $\phi_0(f) = f(u_0)$ for every $f \in V$. **P** Give U the topology $\mathfrak{T}_s(U,V)$ and V' the topology $\mathfrak{T}_s(V',V)$

(4A4Cg). For $u \in U$, $f \in V$ set $\hat{u}(f) = f(u)$; then $u \mapsto \hat{u}$ is a continuous linear operator from U to V' (use 2A3H), so $\hat{K} = \{\hat{u} : u \in K\}$ is a compact convex subset of V'.

? Suppose, if possible, that $\phi_0 \notin \hat{K}$. By (b), there is a continuous linear functional $\boldsymbol{\theta} : V' \to \mathbb{R}$ such that $\boldsymbol{\theta}(\phi) > \sup_{u \in K} \boldsymbol{\theta}(\hat{u})$. But there is an $f \in V$ such that $\boldsymbol{\theta}(\phi) = \phi(f)$ for every $\phi \in V'$ (4A4Cg), so that $\phi_0(f) > \sup_{u \in K} f(u)$, contrary to hypothesis. **X** So there is a $u_0 \in K$ such that $\phi_0 = \hat{u}_0$, as claimed. **Q**

(g) The Bipolar Theorem Let $A \subseteq U'$ be a non-empty set. Set $A^\circ = \{u : u \in U, f(u) \leq 1 \text{ for every } f \in A\}$ (compare 4A4Bh). If $g \in U'$ is such that $g(u) \leq 1$ for every $u \in A^\circ$, then g belongs to the $\mathfrak{T}_s(U', U)$-closed convex hull of $A \cup \{0\}$. **P** Put 4A4Cg and (b) above together, as in (f). See Bourbaki 87, II.6.3; Schaefer 71, IV.1.5; Köthe 69, 20.8. **Q**

4A4F The Mackey topology Let U be a linear space and V a linear subspace of U'. The **Mackey topology** $\mathfrak{T}_k(V, U)$ on V is the topology of uniform convergence on convex $\mathfrak{T}_s(U, V)$-compact subsets of U. Every $\mathfrak{T}_k(V, U)$-continuous linear functional on V is of the form $f \mapsto f(u)$ for some $u \in U$ (use 4A4Ef). So every $\mathfrak{T}_k(V, U)$-closed convex set is $\mathfrak{T}_s(V, U)$-closed, by 4A4Ed. (See Bourbaki 87, IV.1.1; Schaefer 71, IV.3.2; Köthe 69, 21.4.)

4A4G Extreme points (a) Let X be a real linear space, and $C \subseteq X$ a convex set. An element of C is an **extreme** point of C if it is not expressible as a convex combination of two other members of C; equivalently, if it is not expressible as $\frac{1}{2}(x + y)$ where $x, y \in C$ are distinct.

(b) The Kreĭn-Mil'man theorem Let U be a Hausdorff locally convex linear topological space and $K \subseteq U$ a compact convex set. Then K is the closed convex hull of the set of its extreme points. (Bourbaki 87, II.7.1; Schaefer 71, II.10.4; Köthe 69, §25.1; Rudin 91, 3.22.)

(c) Let U and V be Hausdorff locally convex linear topological spaces, $T : U \to V$ a continuous linear operator, $K \subseteq X$ a compact convex set and v any extreme point of $T[K] \subseteq V$. Then there is an extreme point u_0 of K such that $Tu_0 = v$. **P** Set $K_1 = \{u : u \in K, Tu = v\}$. Then K_1 is a compact convex set so has an extreme point u_0. **?** If u_0 is not an extreme point of K, it is expressible as $\alpha u_1 + (1-\alpha)u_2$ where u_1, u_2 are distinct points of K and $\alpha \in]0, 1[$. So $v = \alpha Tu_1 + (1-\alpha)Tu_2$, and we must have $Tu_1 = Tv = Tu_2$, because v is an extreme point of $T[K]$; but this means that u_1, $u_2 \in K_1$ and u_0 is not an extreme point of K_1. **X** So u_0 has the required properties. **Q**

4A4H Proposition Let I be a set, W a closed linear subspace of $\mathbb{R}^I$, U a linear topological space and V a Hausdorff linear topological space. Let $K \subseteq U$ be a compact set and $T : U \times \mathbb{R}^I \to V$ a continuous linear operator. Then $T[K \times W]$ is closed.

proof Take $v_0 \in \overline{T[K \times W]}$. Let $J \subseteq I$ be a maximal set such that

> whenever $L \subseteq J$ is finite and $H \subseteq V$ is an open set containing v_0, there are a $u \in K$ and an $x \in W$ such that $x(i) = 0$ for every $i \in L$ and $T(u, x) \in H$.

Let $\mathcal{F}$ be the filter on $U \times \mathbb{R}^I$ generated by the closed set $K \times W$, the sets $\{(u, x) : x(i) = 0\}$ for $i \in J$, and the sets $T^{-1}[H]$ for open sets H containing v_0. Then for any $j \in I$ there is an $F \in \mathcal{F}$ such that $\{x(j) : (u, x) \in F\}$ is bounded. **P?** Suppose, if possible, otherwise. Then, in particular, $j \notin J$. So there must be a finite set $L \subseteq J$ and an open set H containing v_0 such that $x(j) \neq 0$ whenever $u \in K$, $x \in W$, $x(i) = 0$ for every $i \in L$ and $T(u, x) \in H$. By 2A5C, or otherwise, there is a neighbourhood G_0 of 0 in V such that $v_0 + G_0 - G_0 \subseteq H$ and $\alpha v \in G_0$ whenever $v \in G_0$ and $|\alpha| \leq 1$. Fix $u^* \in K$, $x^* \in W$ such that $x^*(i) = 0$ for every $i \in L$ and $T(u^*, x^*) \in v_0 + G_0$. If $x \in W$ and $x(i) = 0$ for every $i \in L$ and $x(j) = x^*(j)$, then $T(u^*, x^* - x) \notin v_0 + G_0 - G_0$ so $T(0, x) \notin G_0$. It follows that $T(0, x) \notin G_0$ whenever $x \in W$ and $x(i) = 0$ for every $i \in L$ and $|x(j)| \geq |x^*(j)|$.

Let G be a neighbourhood of 0 in V such that $G + G - G - G \subseteq G_0$. We are supposing that $\{x(j) : (u, x) \in F\}$ is unbounded for every $F \in \mathcal{F}$. So for every $n \in \mathbb{N}$ there are $u_n \in K$ and $x_n \in W$ such that $x_n(i) = 0$ for $i \in L$, $T(u_n, x_n) \in v_0 + G$ and $|x_n(j)| \geq n$. Let $u \in K$ be a cluster point of $\langle u_n \rangle_{n \in \mathbb{N}}$. Then $T(u, 0)$ is a cluster point of $\langle T(u_n, 0) \rangle_{n \in \mathbb{N}}$, so $M = \{n : T(u_n, 0) \in T(u, 0) + G\}$ is infinite. For $n \in M$, $T(0, x_n) = T(u_n, x_n) - T(u_n, 0) \in v_0 - T(u, 0) + G - G$; so if $m, n \in M$, $T(0, x_m - x_n) \in G - G - (G - G) \subseteq G_0$.

But note now that $(x_m - x_n)(i) = 0$ for all m, $n \in \mathbb{N}$ and $i \in L$, and that because M is infinite there are certainly m, $n \in M$ such that $|x_m(j) - x_n(j)| \geq |x^*(j)|$; which contradicts the last paragraph. **XQ**

Now let $\mathcal{G}$ be any ultrafilter on $U \times \mathbb{R}^I$ including $\mathcal{F}$. Then for every $i \in I$ there is a $\gamma_i < \infty$ such that $\mathcal{G}$ contains $\{(u, x) : |x(i)| \leq \gamma_i\}$. It follows that $\mathcal{G}$ has a limit $(\hat{u}, \hat{x})$ in $K \times W$. Now the image filter $T[[\mathcal{G}]]$ (2A1Ib) converges to $T(\hat{u}, \hat{x})$; since $T[[\mathcal{F}]] \to v_0$, and the topology of V is Hausdorff, $v_0 = T(\hat{u}, \hat{x}) \in T[K \times W]$. As v_0 is arbitrary, $T[K \times W]$ is closed.

4A4I Normed spaces (a) Two norms $\| \|$, $\| \|'$ on a linear space U give rise to the same topology iff they are **equivalent** in the sense that, for some $M \geq 0$,

$$\|x\| \leq M\|x\|', \quad \|x\|' \leq M\|x\|$$

for every $x \in U$. (Köthe 69, §14.2; Taylor 64, 3.1-D; Jameson 74, 2.8.)

(b) If U and V are normed spaces, $T : U \to V$ is a linear operator and $gT : X \to \mathbb{R}$ is continuous for every $g \in V^*$, then T is a bounded operator. (Jameson 74, 27.6.)

(c) If U is any normed space, its dual U^*, under its usual norm (2A4H), is a Banach space. (Rudin 91, 4.1; Dunford & Schwartz 57, II.3.9; Köthe 69, §14.5.)

(d) If U is a separable normed space, its dual U^* (regarded as a normed space, as in 2A4H) is isometrically isomorphic to a closed linear subspace of ℓ^∞. **P** Let $\langle x_n \rangle_{n \in \mathbb{N}}$ run over a dense subset of the unit ball of U (4A2P(a-iv)); define $T : U^* \to \ell^\infty$ by setting $(Tf)(n) = f(x_n)$ for every n. T is a linear isometry between U^* and $T[U^*]$, which is closed because U^* is complete (4A4Ic, 3A4Fd). **Q**

(e) Let U be a Banach space. Suppose that $\langle u_i \rangle_{i \in I}$ is a family in U such that $\gamma = \sum_{i \in I} \|u_i\| < \infty$.

(i) $\sum_{i \in I} u_i$ is defined in the sense of 4A4Bj. **P** For $J \in [I]^{<\omega}$, set $v_J = \sum_{i \in J} u_i$. For each $n \in \mathbb{N}$, there is a $J_n \in [I]^{<\omega}$ such that $\gamma - \sum_{i \in K} \|u_i\| \leq 2^{-n}$ whenever $J_n \subseteq K \in [I]^{<\omega}$. Now

$$\|v_{J_m} - v_{J_n}\| \leq \sum_{i \in J_m \triangle J_n} \|u_i\| \leq 2^{-m} + 2^{-n}$$

for all m, $n \in \mathbb{N}$, so $\langle v_{J_n} \rangle_{n \in \mathbb{N}}$ is a Cauchy sequence and has a limit v say. If now $n \in \mathbb{N}$ and $J_n \subseteq K \in [I]^{<\omega}$,

$$\begin{aligned} \|v - \sum_{i \in K} u_i\| &= \lim_{m \to \infty} \|v_{J_m} - \sum_{i \in K} u_i\| \leq \limsup_{m \to \infty} \sum_{i \in J_m \triangle K} \|u_i\| \\ &\leq \lim_{m \to \infty} 2^{-m} + 2^{-n} = 2^{-n}, \end{aligned}$$

so $v = \sum_{i \in I} u_i$. **Q**

(ii) Now if $\langle I_j \rangle_{j \in J}$ is any partition of I, $w_j = \sum_{i \in I_j} u_i$ is defined for every j, and $\sum_{j \in J} w_j$ is defined and equal to $\sum_{i \in I} u_i$.

(f) Let U be a normed space. For $u \in U$, define $\hat{u} \in U^{**} = (U^*)^*$ by setting $\hat{u}(f) = f(u)$ for every $f \in U^*$. Then $\{\hat{u} : u \in U, \|u\| \leq 1\}$ is weak*-dense in $\{\phi : \phi \in U^{**}, \|\phi\| = 1\}$. (Apply 4A4Eg with $A = \{\hat{u} : \|u\| \leq 1\}$.)

4A4J Inner product spaces (a) Let U be an inner product space over $\begin{matrix}\mathbb{R}\\ \mathbb{C}\end{matrix}$ (3A5L). An **orthonormal basis** in U is a family $\langle e_i \rangle_{i \in I}$ in U such that (α) $(e_i|e_j) = 0$ if $i \neq j$, 1 if $i = j$ (β) the closed linear subspace of U generated by $\{e_i : i \in I\}$ is U itself.

(b) If U, V are inner product spaces over $\mathbb{R}$ and $T : U \to V$ is an isometry such that $T(0) = 0$, then $(Tu|Tv) = (u|v)$ for all u, $v \in U$ and T is linear. **P** (α)

$$(Tu|Tv) = \tfrac{1}{2}(\|Tu\|^2 + \|Tv\|^2 - \|Tu - Tv\|^2) = \tfrac{1}{2}(\|u\|^2 + \|v\|^2 - \|u - v\|^2) = (u|v).$$

(β) For any u, $v \in U$,

$$\begin{aligned}\|T(u+v)-Tu-Tv\|^2 &= \|T(u+v)\|^2+\|Tu\|^2+\|Tv\|^2\\ &\qquad -2(T(u+v)|Tu)-2(T(u+v)|Tv)+2(Tu|Tv)\\ &= \|u+v\|^2+\|u\|^2+\|v\|^2\\ &\qquad -2(u+v|u)-2(u+v|v)+2(u|v)\\ &= 0.\end{aligned}$$

So T is additive. (γ) Consequently $T(qu)=qTu$ for every $u\in U$ and $q\in\mathbb{Q}$; as T is continuous, it is linear. **Q**

(c) If U is an inner product space over $\begin{matrix}\mathbb{R}\\ \mathbb{C}\end{matrix}$, a linear operator $T:U\to U$ is **self-adjoint** if $(Tu|v)=(u|Tv)$ for all u, $v\in U$.

(d) If U is a finite-dimensional inner product space over $\mathbb{R}$, it is isomorphic to Euclidean space $\mathbb{R}^r$, where $r=\dim U$. (Taylor 64, 3.21-A.) In particular, any finite-dimensional inner product space is a Hilbert space.

(e) If U is an inner product space over $\begin{matrix}\mathbb{R}\\ \mathbb{C}\end{matrix}$ and $V\subseteq U$ is a linear subspace of U, then $V^\perp=\{x : x\in U, (x|y)=0 \text{ for every } y\in V\}$ is a linear subspace of U, and $\|x+y\|^2=\|x\|^2+\|y\|^2$ for $x\in V$, $y\in V^\perp$. If V is complete (in particular, if V is finite-dimensional), then $U=V\oplus V^\perp$. (Rudin 91, 12.4; Bourbaki 87, V.1.6; Taylor 64, 4.82-A.)

(f) If U is an inner product space over $\mathbb{R}$ and v_1, $v_2\in U$ are such that $\|v_1\|=\|v_2\|=1$, there is a linear operator $T:U\to U$ such that $Tv_1=v_2$ and $\|Tu\|=\|u\|$ and $\|Tu-u\|\le\|v_1-v_2\|\|u\|$ for every $u\in U$. **P** If v_2 is a multiple of v_1, say $v_2=\alpha v_1$, take $Tu=\alpha u$ for every u. Otherwise, set $w=v_2-(v_2|v_1)v_1$ and $w_1=\frac{1}{\|w\|}w$, so that $v_2=\cos\theta v_1+\sin\theta w_1$, where $\theta=\arccos(v_2|v_1)$. Let V be the two-dimensional linear subspace of U generated by v_1 and w_1, so that $U=V\oplus V^\perp$. Define a linear operator $T:U\to U$ by saying that $Tv_1=v_2$, $Tw_1=\cos\theta w_1-\sin\theta v_1$ and $Tu=u$ for $u\in V^\perp$. Then T acts on V as a simple rotation through an angle θ, so $\|Tv\|=1$ and $\|Tv-v\|=\|v_2-v_1\|$ whenever $v\in V$ and $\|v\|=1$; generally, if $u\in U$, then $\|Tu\|=\|u\|$ and

$$\|Tu-u\|=\|T(Pu)-Pu\|=\|v_2-v_1\|\|Pu\|\le\|v_2-v_1\|\|u\|,$$

where P is the orthogonal projection of U onto V. **Q**

(g) Let U be an inner product space over $\begin{matrix}\mathbb{R}\\ \mathbb{C}\end{matrix}$, and $\langle u_i\rangle_{i\in I}$ a countable family in U. Then there is a countable orthonormal family $\langle v_j\rangle_{j\in J}$ in U such that $\{v_j : j\in J\}$ and $\{u_i : i\in I\}$ span the same linear subspace of U. **P** We can suppose that $I\subseteq\mathbb{N}$; set $u_i=0$ for $i\in\mathbb{N}\setminus I$. Define $\langle v_n\rangle_{n\in\mathbb{N}}$ inductively by setting $v_n'=u_n-\sum_{i<n}(u_n|v_i)v_i$, $v_n=0$ if $v_n'=0$, $\frac{1}{\|v_n'\|}v_n'$ otherwise. Set $J=\{n : v_n\neq 0\}$. **Q**

4A4K Hilbert spaces (a) If U is a real or complex Hilbert space, its unit ball is compact in the weak topology $\mathfrak{T}_s(U,U^*)$; any bounded set is relatively compact for $\mathfrak{T}_s(U,U^*)$. (Bourbaki 87, V.1.7; Dunford & Schwartz 57, IV.4.6.)

(b) If U is a real or complex Hilbert space, any norm-bounded sequence in U has a weakly convergent subsequence. (462D; Dunford & Schwartz 57, IV.4.7.)

(c) If U is a real or complex Hilbert space and $\langle u_i\rangle_{i\in I}$ is any orthonormal family in U, then it can be extended to an orthonormal basis. (Dunford & Schwartz 57, IV.4.10; Taylor 64, 3.2-I.) In particular, U has an orthonormal basis.

4A4L Compact operators (see 3A5Ka) **(a)** Let U, V and W be Banach spaces. If $T\in\mathrm{B}(U;V)$ and $S\in\mathrm{B}(V;W)$ and either S or T is a compact operator, then ST is compact. (Dunford & Schwartz 57, VI.5.4; Jameson 74, 34.2.)

(b) If U is a Banach space, $T \in \mathrm{B}(U;U)$ is a compact linear operator and $\gamma \neq 0$ then $\{u : Tu = \gamma u\}$ is finite-dimensional. (Rudin 91, 4.18; Taylor 64, 5.5-C; Dunford & Schwartz 57, VII.4.5; Jameson 74, 34.8.)

4A4M Self-adjoint compact operators If U is a Hilbert space and $T : U \to U$ is a self-adjoint compact linear operator, then $T[U]$ is the closed linear span of $\{Tv : v \text{ is an eigenvector of } T\}$. (Taylor 64, 6.4-B.)

4A4N Max-flow Min-cut Theorem (Ford & Fulkerson 56) Let (V, E, γ) be a (finite) transportation network, that is,

V is a finite set of 'vertices',

$E \subseteq \{(v, v') : v, v' \in V, v \neq v'\}$ is a set of (directed) 'edges',

$\gamma : E \to [0, \infty[$ is a function;

we regard a member $e = (v, v')$ of E as 'starting' at v and 'ending' at v', and $\gamma(e)$ is the 'capacity' of the edge e. Suppose that v_0, $v_1 \in V$ are distinct vertices such that no edge ends at v_0 and no edge starts at v_1. Then we have a 'flow' $\phi : E \to [0, \infty[$ and a 'cut' $X \subseteq E$ such that

(i) for every $v \in V \setminus \{v_0, v_1\}$,

$$\sum_{e \in E, e \text{ starts at } v} \phi(e) = \sum_{e \in E, e \text{ ends at } v} \phi(e),$$

(ii) $\phi(e) \leq \gamma(e)$ for every $e \in E$,

(iii) there is no path from v_0 to v_1 using only edges in $E \setminus X$,

(iv) $\sum_{e \in E, e \text{ starts at } v_0} \phi(e) = \sum_{e \in E, e \text{ ends at } v_1} \phi(e) = \sum_{e \in X} \gamma(e)$.

(Bollobás 79, §III.1; Anderson 87, 12.3.1.)

4A5 Topological groups

For Chapter 44 we need a variety of facts about topological groups. Most are essentially elementary, and all the non-trivial ideas are covered by at least one of Császár 78 and Hewitt & Ross 63. In 4A5A-4A5C and 4A5I I give some simple definitions concerning groups and group actions. Topological groups, properly speaking, appear in 4A5D. Their simplest properties are in 4A5E-4A5G. I introduce 'right' and 'bilateral' uniformities in 4A5H; the latter are the more interesting (4A5M-4A5O), but the former are also important (4A5P). 4A5J-4A5L deal with quotient spaces, including spaces of cosets of non-normal subgroups. I conclude with notes on metrizable groups (4A5Q-4A5S).

4A5A Notation If X is a group, $x_0 \in X$, and A, $B \subseteq X$ I write

$$x_0 A = \{x_0 x : x \in A\}, \quad Ax_0 = \{xx_0 : x \in A\},$$

$$AB = \{xy : x \in A, y \in B\}, \quad A^{-1} = \{x^{-1} : x \in A\}.$$

A is **symmetric** if $A = A^{-1}$. Observe that $(AB)C = A(BC)$, $(AB)^{-1} = B^{-1}A^{-1}$ for any A, B, $C \subseteq X$.

4A5B Group actions (a) If X is a group and Z is a set, an **action** of X on Z is a function $(x, z) \mapsto x \bullet z : X \times Z \to Z$ such that

$$(xy) \bullet z = x \bullet (y \bullet z) \text{ for all } x, y \in X \text{ and } z \in Z,$$

$$e \bullet z = z \text{ for every } z \in Z$$

where e is the identity of X.

In this context I may say that 'X acts on Z', taking the operation $\bullet$ for granted.

(b) An action $\bullet$ of a group X on a set Z is **transitive** if for every w, $z \in Z$ there is an $x \in X$ such that $x \bullet w = z$.

(c) If $\bullet$ is an action of a group X on a set Z, I write $x \bullet A = \{x \bullet z : z \in A\}$ whenever $x \in X$ and $A \subseteq Z$.

(d) If $\bullet$ is an action of a group X on a set Z, then $z \mapsto x\bullet z : Z \to Z$ is a bijection for every $x \in X$. (For it has an inverse $z \mapsto x^{-1}\bullet z$.) So if Z is a topological space and $z \mapsto x\bullet z$ is continuous for every x, it is a homeomorphism for every x.

(e) An action $\bullet$ of a group X on a set Z is **faithful** if whenever x, $y \in X$ are distinct there is a $z \in Z$ such that $x\bullet z \neq y\bullet z$; that is, the natural homomorphism from X to the group of bijections from Z to itself is injective. An action of X on Z is faithful iff for any $x \in X$ which is not the identity there is a $z \in Z$ such that $x\bullet z \neq z$.

(f) If $\bullet$ is an action of a group X on a set Z, then $Y_z = \{x : x \in X, x\bullet z = z\}$ is a subgroup of X (the **stabilizer** of z) for every $z \in Z$. If $\bullet$ is transitive, then Y_w and Y_z are conjugate subgroups for all w, $z \in Z$. (If $x\bullet w = z$, then $Y_z = xY_wx^{-1}$.)

4A5C Examples Let X be any group.

(a) Write

$$x\bullet_l y = xy, \quad x\bullet_r y = yx^{-1}, \quad x\bullet_c y = xyx^{-1}$$

for x, $y \in X$. These are all actions of X on itself, the **left**, **right** and **conjugacy** actions.

(b) If $A \subseteq X$, we have an action of X on the set $\{xA : x \in X\}$ defined by setting $x\bullet(yA) = xyA$ for x, $y \in X$.

4A5D Definitions (a) A **topological group** is a group X endowed with a topology such that the operations $(x, y) \mapsto xy : X \times X \to X$ and $x \mapsto x^{-1} : X \to X$ are continuous.

(b) A **Polish group** is a topological group in which the topology is Polish (definition: 4A2A).

4A5E Elementary facts Let X be any topological group.

(a) For any $x \in X$, the functions $y \mapsto xy$, $y \mapsto yx$ and $y \mapsto y^{-1}$ are all homeomorphisms from X to itself. (Hewitt & Ross 63, 4.2; Folland 95, 2.1.)

(b) The maps $(x, y) \mapsto x^{-1}y$, $(x, y) \mapsto xy^{-1}$ and $(x, y) \mapsto xyx^{-1}$ from $X \times X$ to X are continuous.

(c) $\{G : G \text{ is open}, e \in G, G^{-1} = G\}$ is a base of neighbourhoods of the identity e of X. (Hewitt & Ross 63, 4.6; Folland 95, 2.1.)

(d) If $G \subseteq X$ is an open set, then AG and GA are open for any set $A \subseteq X$. (Hewitt & Ross 63, 4.4.)

(e) If $F \subseteq X$ is closed and $x \in X \setminus F$, there is a neighbourhood U of e such that $UxUU \cap FUU = \emptyset$. **P** Set $U_1 = X \setminus x^{-1}F$. Let U_2 be a neighbourhood of e such that $U_2U_2U_2U_2^{-1}U_2^{-1} \subseteq U_1$. Let U be a neighbourhood of e such that $U \subseteq U_2 \cap xU_2x^{-1}$; this works. **Q**

(f) If $K \subseteq X$ is compact and $F \subseteq X$ is closed then KF and FK are closed. If K, $L \subseteq X$ are compact so is KL. (Hewitt & Ross 63, 4.4.)

(g) If there is any compact set $K \subseteq X$ such that $\operatorname{int} K$ is non-empty, then X is locally compact.

(h) If $K \subseteq X$ is compact and $\mathcal{F}$ is a downwards-directed family of closed subsets of X with intersection F_0, then $KF_0 = \bigcap_{F\in\mathcal{F}} KF$ and $F_0K = \bigcap_{F\in\mathcal{F}} FK$. **P** Of course $KF_0 \subseteq \bigcap_{F\in\mathcal{F}} KF$. If $x \in X \setminus KF_0$, then $K^{-1}x \cap F_0$ is empty; because $K^{-1}x$ is compact, there is some $F \in \mathcal{F}$ such that $K^{-1}x \cap F = \emptyset$ (3A3Db), so that $x \notin KF$. Accordingly $KF_0 = \bigcap_{F\in\mathcal{F}} KF$. Similarly, $F_0K = \bigcap_{F\in\mathcal{F}} FK$. **Q**

(i) If $K \subseteq X$ is compact and $G \subseteq X$ is open, then $\{x : xK \subseteq G\}$ and $\{x : Kx \subseteq G\}$ are open. **P** $\{x : xK \not\subseteq G\} = (X \setminus G)K^{-1}\}$, which by (e) above is closed. Similarly, $\{x : Kx \not\subseteq G\} = K^{-1}(X \setminus G)$ is closed. **Q**

(j) If X is Hausdorff, $K \subseteq X$ is compact and U is a neighbourhood of e, there is a neighbourhood V of e such that $xy \in U$ whenever x, $y \in K$ and $yx \in V$; that is, $y^{-1}zy \in U$ whenever $z \in V$ and $y \in K$. **P** If U is open, then $\{xy : x, y \in K, yx \notin U\}$ is a compact set not containing e. Compare 4A5Oc below. **Q**

(k) Any open subgroup of X is also closed. (Császár 78, 11.2.12; Hewitt & Ross 63, 5.5; Folland 95, 2.1.)

(l) If X is locally compact, it has an open subgroup which is σ-compact. (Hewitt & Ross 63, 5.14; Folland 95, 2.3.)

4A5F Proposition (a) Let $(X, \mathfrak{T})$ and $(Y, \mathfrak{S})$ be topological groups. If $\phi : X \to Y$ is a group homomorphism which is continuous at the identity of X, it is continuous. (Császár 78, 11.2.17; Hewitt & Ross 63, 5.40.)

(b) Let X be a group and $\mathfrak{S}$, $\mathfrak{T}$ two topologies on X both making X a topological group. If every $\mathfrak{S}$-neighbourhood of the identity is a $\mathfrak{T}$-neighbourhood of the identity, then $\mathfrak{S} \subseteq \mathfrak{T}$. (Apply (a) to the identity map from $(X, \mathfrak{T})$ to $(X, \mathfrak{S})$.)

4A5G Proposition If $\langle X_i \rangle_{i \in I}$ is any family of topological groups, then $\prod_{i \in I} X_i$, with the product topology and the product group structure, is again a topological group. (Hewitt & Ross 63, 6.2.)

4A5H The uniformities of a topological group Let $(X, \mathfrak{T})$ be a topological group. Write $\mathcal{U}$ for the set of open neighbourhoods of the identity e of X.

(a) For $U \in \mathcal{U}$, set $W_U = \{(x, y) : xy^{-1} \in U\} \subseteq X \times X$. The family $\{W_U : U \in \mathcal{U}\}$ is a filter base, and the filter on $X \times X$ which it generates is a uniformity on X, the **right uniformity** of X. (**Warning!!** Some authors call this the 'left uniformity'.) This uniformity induces the topology $\mathfrak{T}$ (Császár 78, 11.2.7). It follows that $\mathfrak{T}$ is completely regular, therefore regular (4A2Ja, or Hewitt & Ross 63, 8.4).

(b) For $U \in \mathcal{U}$, set $\tilde{W}_U = \{(x, y) : xy^{-1} \in U, x^{-1}y \in U\} \subseteq X \times X$. The family $\{\tilde{W}_U : U \in \mathcal{U}\}$ is a filter base, and the filter on $X \times X$ which it generates is a uniformity on X, the **bilateral uniformity** of X. This uniformity induces the topology $\mathfrak{T}$. (Császár 78, 11.3.c.)

4A5I Definitions If X is a topological group and Z a topological space, an action of X on Z is 'continuous' or 'Borel measurable' if it is continuous, or Borel measurable, when regarded as a function from $X \times Z$ to Z.

Of course the left, right and conjugacy actions of a topological group on itself are all continuous.

4A5J Quotient groups: Proposition Let X be a topological group, Y a subgroup of X, and Z the set of left cosets of Y in X. Set $\pi x = xY$ for $x \in X$.

(a) We have a topology on Z defined by saying that $V \subseteq Z$ is open iff $\pi^{-1}[V]$ is open in X. The canonical map $\pi : X \to Z$ is continuous and open.

(b) Z is Hausdorff iff Y is closed. If X is locally compact, so is Z.

(c) We have a continuous action of X on Z defined by saying that $x \bullet \pi x' = \pi(xx')$ for any x, $x' \in X$.

(d) If Y is a normal subgroup of X, then the group operation on Z renders it a topological group.

proof (a) By Hewitt & Ross 63, 5.15-5.16 the given formula defines a topology on Z for which π is continuous and open.

(b) By Hewitt & Ross 63, 5.21, Z is Hausdorff iff Y is closed. By Hewitt & Ross 63, 5.22 or Folland 95, 2.2, Z is locally compact if X is.

(c) I have noted in 4A5Cb that the formula given defines an action. If $V \subseteq Z$ is open and $x_0 \in X$, $z_0 \in Z$ are such that $x_0 \bullet z_0 \in V$, take $x_0' \in X$ such that $\pi x_0' = z_0$, and observe that $x_0 x_0' \in \pi^{-1}[V]$, which is open. So there are open neighbourhoods V_0, V_0' of x_0, x_0' respectively such that $V_0 V_0' \subseteq \pi^{-1}[V]$, and $x \bullet z \in V$ whenever $x \in V_0$ and $z \in \pi[V_0']$. Since $\pi[V_0']$ is an open neighbourhood of z_0, this is enough to show that $\bullet$ is continuous at (x_0, z_0).

(d) Császár 78, 11.2.15; Hewitt & Ross 63, 5.26; Folland 95, 2.2.

4A5K Proposition Let X be a topological group with identity e.
(a) $Y = \overline{\{e\}}$ is a closed normal subgroup of X.
(b) Writing $\pi : X \to X/Y$ for the canonical map,
(i) a subset of X is open iff it is the inverse image of an open subset of X/Y,
(ii) a subset of X is closed iff it is the inverse image of a closed subset of X/Y,
(iii) $\pi[G]$ is a regular open set in X/Y for every regular open set $G \subseteq X$,
(iv) $\pi[F]$ is nowhere dense in X/Y for every nowhere dense set $F \subseteq X$,
(v) $\pi^{-1}[V]$ is nowhere dense in X for every nowhere dense $V \subseteq X/Y$.

proof (a) Császár 78, 11.2.13; Hewitt & Ross 63, 5.4; Folland 95, 2.3.

(b)(i)-(ii) If $G \subseteq X$ is open and $x \in G$, then $x\overline{\{e\}} = \overline{\{x\}} \subseteq G$, because X is regular (4A5Ha). So $G = GY = \pi^{-1}[\pi[G]]$. Since π is an open map (4A5Ja), $\pi[G]$ is open and G is the inverse image of an open set. If $F \subseteq X$ is closed,

$$F = X \setminus \pi^{-1}[\pi[X \setminus F]] = \pi^{-1}[(X/Y) \setminus \pi[X \setminus F]]$$

is the inverse image of a closed set, and $\pi[F] = (X/Y) \setminus \pi[X \setminus F]$ is closed.

Conversely, because π is continuous, the inverse image of an open or closed set is again open or closed.

(iii) If $A \subseteq X$, then $\pi[\overline{A}]$ is a closed set included in $\overline{\pi[A]}$ (because π is continuous), so $\overline{\pi[A]} = \pi[\overline{A}]$. If $G \subseteq X$ is a regular open set, then $\pi^{-1}[\operatorname{int}\pi[\overline{G}]]$ is an open subset of $\pi^{-1}[\pi[\overline{G}]] = \overline{G}$, so is included in $\operatorname{int}\overline{G} = G$. But this means that the open set $\pi[G]$ includes $\operatorname{int}\pi[\overline{G}] = \operatorname{int}\overline{\pi[G]}$, and $\pi[G] = \operatorname{int}\overline{\pi[G]}$ is a regular open set.

(iv) If $F \subseteq X$ is nowhere dense, then its closure is of the form $\pi^{-1}[V]$ for some closed set $V \subseteq X/Y$. Now if $H \subseteq X/Y$ is a non-empty open set, $\pi^{-1}[H]$ is a non-empty open subset of X, so is not included in F, and H cannot be included in V. Thus V is nowhere dense; but $V \supseteq \pi[F]$, so $\pi[F]$ is nowhere dense.

(v) If $V \subseteq X/Y$ is nowhere dense, and $G \subseteq X$ is open and not empty, then $G = \pi^{-1}[H]$ for some non-empty open $H \subseteq X/Y$. In this case, $H \setminus \overline{V}$ is non-empty, so $\pi^{-1}[H \setminus \overline{V}]$ is a non-empty open subset of G disjoint from $\pi^{-1}[V]$. As G is arbitrary, $\pi^{-1}[V]$ is nowhere dense.

4A5L Theorem Let X be a topological group and Y a normal subgroup of X. Let $\pi : X \to X/Y$ be the canonical homomorphism.
(a) If X' is another topological group and $\phi : X \to X'$ a continuous homomorphism with kernel included in Y, then we have a continuous homomorphism $\psi : X/Y \to X'$ defined by the formula $\psi\pi = \phi$; ψ is injective iff Y is the kernel of ϕ.
(b) Suppose that K_1, K_2 are two subgroups of X/Y such that $K_2 \lhd K_1$. Set $Y_1 = \pi^{-1}[K_1]$ and $Y_2 = \pi^{-1}[K_2]$. Then $Y_2 \lhd Y_1$ and Y_1/Y_2 and K_1/K_2 are isomorphic as topological groups.

proof (a) This is elementary group theory, except for the claim that ψ is continuous. But if $H \subseteq X'$ is open, then $\psi^{-1}[H] = \pi[\phi^{-1}[H]]$ is open because ϕ is continuous and π is open (4A5Ja); so ψ is continuous.

(b) See Hewitt & Ross 63, 5.35.

4A5M Proposition Let X be a topological group.
(a) Let Y be any subgroup of X. If X is given its bilateral uniformity, then the subspace uniformity on Y is the bilateral uniformity of Y. (Császár 78, 11.3.13.)
(b) If X is locally compact it is complete under its right uniformity. (Császár 78, 11.3.21.) If X is complete under its right uniformity it is complete under its bilateral uniformity. (Császár 78, 11.3.10.)
(c) Suppose that X is Hausdorff and that Y is a subgroup of X which is locally compact in its subspace topology. Then Y is closed in X. **P** Putting (a) and (b) together, we see that Y is complete in its subspace uniformity; by 3A4Fd, it is closed. **Q**

4A5N Theorem Let X be a Hausdorff topological group. Then its completion $\widehat{X}$ under its bilateral uniformity can be endowed (in exactly one way) with a group structure rendering it a Hausdorff topological group in which the natural embedding of X in $\widehat{X}$ represents X as a dense subgroup of $\widehat{X}$. (Császár 78, 11.3.15.) If X has a neighbourhood of the identity which is totally bounded for the bilateral uniformity, then $\widehat{X}$ is locally compact. (Császár 78, 11.3.24.)

4A5O Proposition Let X be a topological group.

(a) If $A \subseteq X$, then the following are equiveridical: (i) A is totally bounded for the bilateral uniformity of X; (ii) for every neighbourhood U of the identity there is a finite set $I \subseteq X$ such that $A \subseteq IU \cap UI$.

(b) If A, $B \subseteq X$ are totally bounded for the bilateral uniformity of X, so are $A \cup B$, A^{-1} and AB. In particular, $\bigcup_{i \leq n} x_i B$ is totally bounded for any $x_0, \ldots, x_n \in X$.

(c) If $A \subseteq X$ is totally bounded for the bilateral uniformity, and U is any neighbourhood of the identity, then $\{y : xyx^{-1} \in U \text{ for every } x \in A\}$ is a neighbourhood of the identity.

(d) If X is the product of a family $\langle X_i \rangle_{i \in I}$ of topological groups, a subset A of X is totally bounded for the bilateral uniformity of X iff it is included in a product $\prod_{i \in K} A_i$ where $A_i \subseteq X_i$ is totally bounded for the bilateral uniformity of X_i for every $i \in I$.

(e) If X is locally compact, a subset of X is totally bounded for the bilateral uniformity iff it is relatively compact.

proof (a)(i)⇒(ii) Suppose that A is totally bounded, and that U is a neighbourhood of the identity e of X. Set

$$W = \{(x, y) : xy^{-1} \in U^{-1},\ x^{-1}y \in U\} = \{(x, y) : y \in Ux \cap xU\};$$

then W belongs to the uniformity, so there is a finite set $I \subseteq X$ such that $A \subseteq W[I]$. But $W[I] \subseteq UI \cap IU$, so $A \subseteq UI \cap IU$.

(ii)⇒(i) Now suppose that A satisfies the condition, and that W belongs to the uniformity. Then there is a neighbourhood U of e such that $\{(x, y) : xy^{-1} \in U,\ x^{-1}y \in U\} \subseteq W$. Let V be a neighbourhood of e such that $VV^{-1} \subseteq U$ and $V^{-1}V \subseteq U$. Let $I \subseteq X$ be a finite set such that $A \subseteq VI \cap IV$. For w, $z \in I$ set $A_{wz} = A \cap Vw \cap zV$. If x, $y \in A_{wz}$, $xy^{-1} \in Vww^{-1}V^{-1} \subseteq U$ and $x^{-1}y \in V^{-1}z^{-1}zV \subseteq U$. But this means that $A_{wz} \times A_{wz} \subseteq W$. So if we take a finite set J which meets every non-empty A_{wz}, $A \subseteq W[J]$. As W is arbitrary, A is totally bounded.

(b) Of course $A \cup B$ is totally bounded; this is immediate from the definition of 'totally bounded'. If U is a neighbourhood of e, so is U^{-1}, so there is a finite set $I \subseteq X$ such that $A \subseteq IU^{-1} \cap U^{-1}I$ and $A^{-1} \subseteq UI^{-1} \cap I^{-1}U$; as U is arbitrary, A^{-1} is totally bounded.

To see that AB is also totally bounded, let U be a neighbourhood of e, and take a neighbourhood V of e such that $VV \subseteq U$. Then there is a finite set $I \subseteq X$ such that $A \subseteq VI$ and $B \subseteq IV$. Let W be a neighbourhood of e such that $zWz^{-1} \cup z^{-1}Wz \subseteq V$ for every $z \in I$, and J a finite set such that $B \subseteq WJ$ and $A \subseteq JW$. Then

$$zW \subseteq Vz, \quad Wz \subseteq zV$$

for every $z \in I$, so

$$IW \subseteq VI, \quad WI \subseteq IV$$

and

$$AB \subseteq VIWJ \subseteq VVIJ \subseteq UK, \quad AB \subseteq JWIV \subseteq JIVV \subseteq KU$$

where $K = IJ \cup JI$ is finite. As U is arbitrary, AB is totally bounded.

(c) Let V be a neighbourhood of e such that $VVV^{-1} \subseteq U$. Let I be a finite set such that $A \subseteq VI$. Let W be a neighbourhood of e such that $zWz^{-1} \subseteq V$ for every $z \in I$. If now $y \in W$ and $x \in A$, there is a $z \in I$ such that $x \in Vz$, so that

$$xyx^{-1} \in VzWz^{-1}V^{-1} \subseteq VVV^{-1} \subseteq U.$$

Turning this round, $\{y : xyx^{-1} \in U \text{ for every } x \in A\}$ includes W and is a neighbourhood of e.

(d)(i) Suppose that A is totally bounded. Set $A_k = \pi_k[A]$ for each $k \in K$, where $\pi_k(x) = x(k)$ for $x \in X$. If U is a neighbourhood of the identity in X_k, then $V = \pi_k^{-1}[U]$ is a neighbourhood of the identity in X, so there is a finite set $I \subseteq X$ such that $A \subseteq IV \cap VI$; now $A_k \subseteq JU \cap UJ$, where $J = \pi_k[I]$ is finite. As U is arbitrary, A_k is totally bounded. This is true for every k, and $A \subseteq \prod_{k \in K} A_k$.

(ii) Suppose that $A \subseteq \prod_{k \in K} A_k$ where $A_k \subseteq X_k$ is totally bounded for each $k \in K$. If A is empty, of course it is totally bounded; assume that $A \neq \emptyset$. If $K = \emptyset$, then $X = \{\emptyset\}$ is the trivial group, and again

A is totally bounded; so assume that K is non-empty. Let V be a neighbourhood of the identity in X. Then there are a non-empty finite set $L \subseteq K$ and a family $\langle U_k \rangle_{k \in L}$ such that U_k is a neighbourhood of the identity in X_k for each $k \in L$, and $V \supseteq \bigcap_{k \in L} \pi_k^{-1} U_k$. For each $k \in L$, let I_k be a finite subset of X_k such that $A_k \subseteq I_k U_k \cap U_k I_k$. Set

$$I = \{x : x \in X, \, x(k) \text{ is the identity for } k \in K \setminus L, \, x(k) \in I_k \text{ for } k \in L\}.$$

Then I is finite and $A \subseteq IV \cap VI$. As V is arbitrary, A is totally bounded.

(e) By 4A5Mb and 4A2Jd, the totally bounded sets are the relatively compact sets.

4A5P Lemma Let X be a locally compact Hausdorff topological group. Take $f \in C_k(X)$, the space of continuous real-valued functions on X with compact supports.

(a) Let $K \subseteq X$ be a compact set. Then for any $\epsilon > 0$ there is a neighbourhood W of the identity E of X such that $|f(xay) - f(xby)| \leq \epsilon$ whenever $x \in K$, $y \in X$ and $ab^{-1} \in W$.

(b) For any $x_0 \in X$, there is a non-negative $f^* \in C_k(X)$ such that for every $\epsilon > 0$ there is an open set G containing x_0 such that $|f(xy) - f(x_0 y)| \leq \epsilon f^*(y)$ for every $x \in G$ and $y \in X$.

proof (a) By 4A2Je and 4A5Ha, f is uniformly continuous for the right uniformity of X. There is therefore a symmetric neighbourhood U of e, included in V, such that $|f(y_1) - f(y_2)| \leq \epsilon$ whenever y_1, $y_2 \in X$ and $y_1 y_2^{-1} \in U$. By 4A5Oc, there is a symmetric neighbourhood W of e such that $xzx^{-1} \in U$ whenever $x \in K$ and $z \in W$.

Now suppose that $x \in K$, $y \in X$ and $ab^{-1} \in W$. Then $(xay)(xby)^{-1} = xab^{-1}x^{-1} \in U$, so $|f(xay) - f(xby)| \leq \epsilon$, as required.

(b) We need a trifling refinement of the ideas above.

(i) Suppose for the moment that $x_0 = e$. Set $L = \overline{\{x : f(x) \neq 0\}}$ and let V be a compact symmetric neighbourhood of the identity e, so that L and VL are compact. Let $f^* \in C_k(X)$ be such that $f^* \geq \chi(VL)$ (4A2G(e-i)). Given $\epsilon > 0$, take U as in (a), so that U is a symmetric neighbourhood of e and $|f(y_1) - f(y_2)| \leq \epsilon$ whenever $y_1 y_2^{-1} \in U$; this time arrange further that $U \subseteq V$. Then if $x \in U$ and $y \in X$,

either y and xy belong to VL, while $(xy)y^{-1} \in U$, so $|f(xy) - f(y)| \leq \epsilon \leq \epsilon f^*(y)$

or neither y nor xy belongs to L, so $|f(xy) - f(y)| = 0 \leq \epsilon f^*(y)$.

(ii) For the general case, set $f_0(x) = f(x_0 x)$ for $x \in X$. Because $x \mapsto x_0 x$ is a homeomorphism, $f_0 \in C_k(X)$. By (i), we have a non-negative $f^* \in C_k(X)$ such that for every $\epsilon > 0$ there is a neighbourhood G_ϵ of e such that $|f_0(xy) - f_0(y)| \leq \epsilon f^*(y)$ whenever $x \in G_\epsilon$ and $y \in X$. Now, given $\epsilon > 0$, $G' = x_0 G_\epsilon$ is a neighbourhood of x_0 and $|f(xy) - f(x_0 y)| \leq \epsilon f^*(y)$ whenever $x \in G'$ and $y \in X$. So f^* witnesses that the result is true.

4A5Q Metrizable groups: Proposition Let $(X, \mathfrak{T})$ be a topological group. Then the following are equiveridical:

(i) X is metrizable;

(ii) the identity e of X has a countable neighbourhood base;

(iii) there is a metric ρ on X, inducing the topology $\mathfrak{T}$, which is **right-translation-invariant**, that is, $\rho(x_1, x_2) = \rho(x_1 y, x_2 y)$ for all x_1, x_2, $y \in X$;

(iv) there is a right-translation-invariant metric on X which induces the right uniformity of X.

proof Császár 78, 11.2.10; Hewitt & Ross 63, 8.3.

Warning! A Polish group (4A5Db) is of course metrizable, so has a right-translation-invariant metric inducing its topology. At the same time, it has a complete metric inducing its topology. But there is no suggestion that these two metrics should be the same, or even induce the same uniformity.

4A5R Corollary If X is a locally compact topological group and $\{e\}$ is a G_δ set in X, then X is metrizable. (Put 4A5Q and 4A2Kf together, or see Hewitt & Ross 63, 8.5.)

4A5S Lemma Let X be a σ-compact locally compact Hausdorff topological group and $\langle U_n\rangle_{n\in\mathbb{N}}$ any sequence of neighbourhoods of the identity in X. Then X has a compact normal subgroup $Y \subseteq \bigcap_{n\in\mathbb{N}} U_n$ such that X/Y is metrizable.

proof Let $\langle K_n\rangle_{n\in\mathbb{N}}$ be a sequence of compact sets covering X. Choose inductively a sequence $\langle V_n\rangle_{n\in\mathbb{N}}$ of compact neighbourhoods of e such that, for each $n \in \mathbb{N}$,

(α) $V_{n+1} \subseteq V_n^{-1}$, $\quad V_{n+1}V_{n+1} \subseteq V_n$, $\quad V_n \subseteq U_n$,

(β) $xyx^{-1} \in V_n$ whenever $y \in V_{n+1}$ and $x \in \bigcup_{i\le n} K_i$.

(When we come to choose V_{n+1}, we can achieve (α) because inversion and multiplication are continuous, and (β) by 4A5Oc; and we can then shrink V_{n+1} to a closed neighbourhood of e because X is regular, by 4A5Ha.) Set $Y = \bigcap_{n\in\mathbb{N}} V_n$. Then ($\alpha$) is enough to ensure that Y is a compact subgroup of X included in $\bigcap_{n\in\mathbb{N}} U_n$, while ($\beta$) ensures that Y is normal, because for any $x \in X$ there is an $n \in \mathbb{N}$ such that $xV_{m+1}x^{-1} \subseteq V_m$ for every $m \ge n$.

Let $\pi : X \to X/Y$ be the canonical map. Then $C = \bigcap_{n\in\mathbb{N}} \pi[\operatorname{int} V_n]$ is a G_δ subset of X/Y, because π is open. But

$$\pi^{-1}[C] \subseteq \bigcap_{n\in\mathbb{N}} \pi^{-1}[\pi[V_{n+1}]] = \bigcap_{n\in\mathbb{N}} V_{n+1}Y \subseteq \bigcap_{n\in\mathbb{N}} V_n = Y,$$

so $C = \{e_{X/Y}\}$, writing $e_{X/Y}$ for the identity of X/Y. Thus $\{e_{X/Y}\}$ is a G_δ set; as X/Y is locally compact and Hausdorff (4A5Jb), it is metrizable (4A5R).

***4A5T** I shall not rely on the following fact, but it will help you to make sense of some of the results of this volume.

Theorem A compact Hausdorff topological group is dyadic.

proof Uspenskiĭ 88.

4A6 Banach algebras

I give results which are needed for Chapter 44. Those down to 4A6K should be in any introductory text on normed algebras; 4A6L-4A6N, as expressed here, are a little more specialized. As with normed spaces or linear topological spaces, Banach algebras may be defined over either $\mathbb{R}$ or $\mathbb{C}$. In §445 we need complex Banach algebras, but in §446 I think the ideas are clearer in the context of real Banach algebras. Accordingly, as in §2A4, I express as much as possible of the theory in terms applicable equally to either, speaking of 'normed algebras' or 'Banach algebras' without qualification, and using the symbol $\begin{smallmatrix}\mathbb{R}\\ \mathbb{C}\end{smallmatrix}$ to represent the field of scalars. Since (at least, if you keep to the path indicated here) the ideas are independent of which field we work with, you will have no difficulty in applying the arguments given in Folland 95 or Hewitt & Ross 63 for the complex case to the real case. In 4A6B and 4A6I-4A6K, however, we have results which apply only to 'complex' Banach algebras, in which the underlying field is taken to be $\mathbb{C}$.

4A6A Definition (a) I repeat a definition from §2A4. A **normed algebra** is a normed space U together with a multiplication, a binary operator $\times$ on U, such that

$$u \times (v \times w) = (u \times v) \times w,$$

$$u \times (v + w) = (u \times v) + (u \times w), \quad (u + v) \times w = (u \times w) + (v \times w),$$

$$(\alpha u) \times v = u \times (\alpha v) = \alpha(u \times v),$$

$$\|u \times v\| \le \|u\|\|v\|$$

for all u, v, $w \in U$ and $\alpha \in \begin{smallmatrix}\mathbb{R}\\ \mathbb{C}\end{smallmatrix}$. A normed algebra is **commutative** if its multiplication is commutative.

(b) A **Banach algebra** is a normed algebra which is a Banach space. A **unital Banach algebra** is a Banach algebra with a multiplicative identity e such that $\|e\| = 1$. (**Warning:** some authors reserve the term 'Banach algebra' for what I call a 'unital Banach algebra'.)

In a unital Banach algebra I will always use the letter e for the identity.

4A6B Stone-Weierstrass Theorem: fourth form Let X be a locally compact Hausdorff space, and $C_0 = C_0(X;\mathbb{C})$ the complex Banach algebra of continuous functions $f : X \to \mathbb{C}$ such that $\{x : |f(x)| \geq \epsilon\}$ is compact for every $\epsilon > 0$. Let $A \subseteq C_0$ be such that

A is a linear subspace of C_0;

$f \times g \in A$ for every f, $g \in A$;

the complex conjugate $\bar{f}$ of f belongs to A for every $f \in A$;

for every $x \in X$ there is an $f \in A$ such that $f(x) \neq 0$:

whenever x, y are distinct points of X there is an $f \in A$ such that $f(x) \neq f(y)$.

Then A is $\| \ \|_\infty$-dense in C_0.

proof Let $X_\infty = X \cup \{\infty\}$ be the one-point compactification of X (3A3O). For $f \in C_0$ write $f^\#$ for the extension of f to $X \cup \{\infty\}$ with $f^\#(\infty) = 0$, so that $f^\# \in C_b(X_\infty;\mathbb{C})$. Let $B \subseteq C_b(X_\infty;\mathbb{C})$ be the set of all functions of the form $f^\# + \alpha\chi X_\infty$ where $f \in A$ and $\alpha \in \mathbb{C}$. Then B is a subalgebra of $C_b(X \cup \{\infty\})$ which contains complex conjugates of its members and constant functions and separates the points of X_∞.

Take any $h \in C_0$ and $\epsilon > 0$. By the 'third form' of the Stone-Weierstrass theorem (281G), there is a $g \in B$ such that $\|g - h^\#\|_\infty \leq \frac{1}{2}\epsilon$. Express g as $f^\# + \alpha\chi X_\infty$ where $f \in A$ and $\alpha \in \mathbb{C}$. Then

$$|\alpha| = |g(\infty)| = |g(\infty) - h^\#(\infty)| \leq \tfrac{1}{2}\epsilon,$$

so

$$\|h - f\|_\infty = \|h^\# - f^\#\|_\infty \leq \|h^\# - g\|_\infty + \|g - f^\#\|_\infty \leq \tfrac{1}{2}\epsilon + |\alpha| \leq \epsilon.$$

As h and ϵ are arbitrary, A is dense in C_0.

4A6C Proposition If U is any Banach space other than $\{0\}$, then the space $\mathbb{B}(U;U)$ of bounded linear operators from U to itself is a unital Banach algebra. (Köthe 69, 14.6.)

4A6D Proposition Any normed algebra U can be embedded as a subalgebra of a unital Banach algebra V, in such a way that if U is commutative so is V. (Folland 95, §1.3; Hewitt & Ross 63, C.3.)

4A6E Proposition Let U be a unital Banach algebra and $W \subseteq U$ a closed proper ideal. Then U/W, with the quotient linear structure, ring structure and norm, is a unital Banach algebra. (Hewitt & Ross 63, C.2.)

4A6F Proposition If U is a Banach algebra and $\phi : U \to \begin{matrix}\mathbb{R}\\ \mathbb{C}\end{matrix}$ is a multiplicative linear functional, then $|\phi(u)| \leq \|u\|$ for every $u \in U$.

proof ? Otherwise, there is a u such that $|\phi(u)| > \|u\|$; set $v = \frac{1}{\phi(u)}u$, so that $\phi(v) = 1$ and $\|v\| < 1$. Since $\|v^n\| \leq \|v\|^n$ for every $n \geq 1$, $w = \sum_{n=1}^\infty v^n$ is defined in U (4A4Ie), and $w = vw + v$. But this means that $\phi(w) = \phi(v)\phi(w) + \phi(v) = \phi(w) + 1$, which is impossible. **X**

4A6G Definition Let U be a normed algebra and $u \in U$.

(a) For any $u \in U$, $\lim_{n\to\infty} \|u^n\|^{1/n}$ is defined and equal to $\inf_{n\geq 1} \|u^n\|^{1/n}$. (Hewitt & Ross 63, C.4.)

(b) This common value is called the **spectral radius** of u.

4A6H Theorem If U is a unital Banach algebra, then the set R of invertible elements is open, and $u \mapsto u^{-1}$ is a continuous function from R to itself. Writing e for the identity of U, $v \in R$ and $\|v^{-1} - e\| \leq \frac{\|v-e\|}{1-\|v-e\|}$ whenever $\|v - e\| < 1$. (Folland 95, 1.4; Hewitt & Ross 63, C.8 & C.10; Rudin 91, 10.7 & 10.12.)

4A6I Theorem Let U be a complex unital Banach algebra and $u \in U$. Write r for the spectral radius of u.

(a) If $\zeta \in \mathbb{C}$ and $|\zeta| > r$ then $\zeta e - u$ is invertible.

(b) There is a ζ such that $|\zeta| = r$ and $\zeta e - u$ is not invertible.

proof Folland 95, 1.8; Hewitt & Ross 63, C.24; Rudin 91, 1.13.

4A6J Theorem Let U be a commutative complex unital Banach algebra, and $u \in U$. Then for any $\zeta \in \mathbb{C}$ the following are equiveridical:

(i) there is a non-zero multiplicative linear functional $\phi : U \to \mathbb{C}$ such that $\phi(u) = \zeta$;

(ii) $\zeta e - u$ is not invertible.

proof Folland 95, 1.13; Hewitt & Ross 63, C.20; Rudin 91, 11.5.

4A6K Corollary Let U be a commutative complex Banach algebra and $u \in U$. Then its spectral radius $r(u)$ is $\max\{|\phi(u)| : \phi \text{ is a multiplicative linear functional on } U\}$. (Folland 95, 1.13; Hewitt & Ross 63, C.20; Rudin 91, 11.9.)

4A6L Exponentiation Let U be a unital Banach algebra. For any $u \in U$, $\sum_{k=0}^{\infty} \|\frac{1}{k!}u^k\| \leq \sum_{k=0}^{\infty} \frac{1}{k!}\|u\|^k$ is finite, so

$$\exp(u) = \sum_{k=0}^{\infty} \frac{1}{k!}u^k$$

is defined in U (4A4Ie). (In this formula, interpret u^0 as e for every u.)

4A6M Lemma Let U be a unital Banach algebra.

(a) If u, $v \in U$ and $\max(\|u\|, \|v\|) \leq \gamma$ then $\|\exp(u) - \exp(v) - u + v\| \leq \|u - v\|(\exp(\gamma) - 1)$. So if $\max(\|u\|, \|v\|) \leq \frac{1}{2}$ and $\exp(u) = \exp(v)$ then $u = v$.

(b) If $\|u - e\| \leq \frac{1}{6}$ then there is a v such that $\exp(v) = u$ and $\|v\| \leq 2\|u - e\|$.

(c) If u, $v \in U$ and $uv = vu$ then $\exp(u + v) = \exp(u)\exp(v)$.

proof (a) Note first that if $k \geq 1$ then

$$\begin{aligned}\|u^k - v^k\| &= \|\sum_{i=0}^{k-1} u^{k-i}v^i - u^{k-i-1}v^{i+1}\| = \|\sum_{i=0}^{k-1} u^{k-i-1}(u - v)v^i\| \\ &\leq \sum_{i=0}^{k-1} \|u\|^{k-i-1}\|u - v\|\|v\|^i \leq \sum_{i=0}^{k-1} \gamma^{k-1}\|u - v\| = k\gamma^{k-1}\|u - v\|.\end{aligned}$$

So

$$\begin{aligned}\|\exp(u) - \exp(v) - u + v\| &= \|\sum_{k=2}^{\infty} \frac{1}{k!}(u^k - v^k)\| \leq \sum_{k=2}^{\infty} \frac{1}{k!}\|u^k - v^k\| \\ &\leq \sum_{k=2}^{\infty} \frac{k}{k!}\gamma^{k-1}\|u - v\| = \|u - v\|(\exp(\gamma) - 1).\end{aligned}$$

Now if $\exp(u) = \exp(v)$ and $\gamma \leq \frac{1}{2}$, $\exp(\gamma) - 1 < 1$ so $\|u - v\| = 0$ and $u = v$.

(b) Set $\gamma = \|u - e\|$. Define $\langle v_n \rangle_{n \in \mathbb{N}}$ in U by setting $v_0 = 0$, $v_{n+1} = v_n + u - \exp(v_n)$ for $n \in \mathbb{N}$. Then

$$\|v_{n+1} - v_n\| = \|u - \exp(v_n)\| \leq 2^{-n}\gamma, \quad \|v_n\| \leq 2(1 - 2^{-n})\gamma$$

for every $n \in \mathbb{N}$. **P** Induce on n. The induction starts with $\|v_0\| = 0$ and $\|u - \exp(v_0)\| = \|u - e\| = \gamma$. Given that $\|v_n\| \leq 2(1 - 2^{-n})\gamma$ and $\|u - \exp(v_n)\| \leq 2^{-n}\gamma$, then

$$\|v_{n+1}\| \le \|v_n\| + \|v_{n+1} - v_n\| = \|v_n\| + \|u - \exp(v_n)\|$$
$$\le 2(1 - 2^{-n})\gamma + 2^{-n}\gamma = 2(1 - 2^{-n-1})\gamma.$$

Now $\max(\|v_{n+1}\|, \|v_n\|) \le 2\gamma \le \frac{1}{3}$, so

$$\|u - \exp(v_{n+1})\| = \|v_{n+1} - v_n + \exp(v_n) - \exp(v_{n+1})\| \le \|v_{n+1} - v_n\|(\exp(\tfrac{1}{3}) - 1)$$
$$\le \tfrac{1}{2}\|v_{n+1} - v_n\| \le 2^{-n-1}\gamma,$$

and the induction continues. **Q**

Since $\sum_{n=0}^{\infty} \|v_{n+1} - v_n\|$ is finite, $v = \lim_{n\to\infty} v_n$ is defined in U, and $\|v\| = \lim_{n\to\infty} \|v_n\| \le 2\gamma$. Accordingly

$$\|\exp(v) - \exp(v_n)\| \le \|v - v_n\| + \|\exp(v) - \exp(v_n) - v + v_n\|$$
$$\le \|v - v_n\|(1 + \exp(\tfrac{1}{3}) - 1) \to 0$$

as $n \to \infty$, and $\exp(v) = \lim_{n\to\infty} \exp(v_n) = u$.

(c) Because $uv = vu$, $(u+v)^m = \sum_{j=0}^{m} \frac{m!}{j!(m-j)!} u^j v^{m-j}$ for every $m \in \mathbb{N}$ (induce on m; the point is that $uv^j = v^j u$ for every $j \in \mathbb{N}$). Next, $\sum_{j,k\in\mathbb{N}} \frac{1}{j!k!}\|u\|^j\|v\|^k$ is finite. So

$$\exp(u+v) = \sum_{m=0}^{\infty} \frac{1}{m!}(u+v)^m$$
$$= \sum_{m=0}^{\infty} \Big(\sum_{j+k=m} \frac{1}{j!k!} u^j v^k \Big) = \sum_{(j,k)\in\mathbb{N}\times\mathbb{N}} \frac{1}{j!k!} u^j v^k$$

(using 4A4I(e-ii))

$$= \sum_{j\in\mathbb{N}} \Big(\sum_{k\in\mathbb{N}} \frac{1}{j!k!} u^j v^k \Big)$$

(4A4I(e-ii) again)

$$= \sum_{j\in\mathbb{N}} \Big(\frac{1}{j!} u^j \sum_{k\in\mathbb{N}} \frac{1}{k!} v^k \Big)$$

(by 4A4Bj, because $w \mapsto \frac{1}{j!}u^j w$ is a continuous linear operator for each j)

$$= \sum_{j\in\mathbb{N}} \frac{1}{j!} u^j \exp(v) = \Big(\sum_{j\in\mathbb{N}} \frac{1}{j!} u^j \Big) \exp(v)$$

(4A4Bj again)

$$= \exp(u)\exp(v),$$

as claimed.

4A6N Lemma If U is any unital Banach algebra, $u \in U$ and $u \ne e$, there is some $n \in \mathbb{N}$ such that $\|u^n - e\| > \frac{1}{6}$.

proof ? Otherwise, for every $n \in \mathbb{N}$ take v_n such that $\exp(v_n) = u^{2^n}$ and $\|v_n\| \le \frac{1}{3}$ (4A6Mb). Then $\exp(v_{n+1}) = \exp(v_n)^2 = \exp(2v_n)$ (4A6Mc) and $\|v_{n+1}\| \le \frac{1}{3}$, $\|2v_n\| \le \frac{1}{3}$ so $v_{n+1} = 2v_n$ for every n (4A6Ma). Inducing on n, $v_n = 2^n v_0$ for every n, so that $\|v_0\| \le 2^{-n}\|v_n\| \to 0$ as $n \to \infty$, and $u = \exp(v_0) = e$. **X**

Concordance

I list here the section and paragraph numbers which have (to my knowledge) appeared in print in references to this volume, and which have since been changed.

411I Completion regular measures The definition of 'completion regular' measure, referred to in FREMLIN 00, has been moved to 411J.

414N Density topologies The note on 'density topologies', referred to in the 2001 edition of Volume 2, has been moved to 414P.

415Yd Sorgenfrey topology This exercise, referred to in the 2001 edition of Volume 2, has been moved to 415Ye.

416P The algebra of open-and-closed subsets This paragraph, referred to in the 2002 edition of Volume 3, has been moved to 416Q.

416T Kakutani's theorem The description of the usual measure on $\{0,1\}^\kappa$, referred to in FREMLIN & PLEBANEK 03, has been moved to 416U.

417E τ-additive product measures The reference in FREMLIN 00 to Kakutani's theorem that the product measure on $\{0,1\}^I$ is completion regular should be directed to 415E or 416U rather than 417E.

§**445 Convolutions** The material mentioned in the 2001 edition of Volume 2 has been moved to §444. The particular result referred to as '445K' is now 444R.

445Xq The exercise 445Xq, referred to in the 2002 edition of Volume 3, has been moved to 445Xp.

452I In FREMLIN 00 I quote Pachl's result that if (X,Σ,μ) is countably compact, (Y,T,ν) is strictly localizable and $f:X\to Y$ is inverse-measure-preserving, then ν is countably compact; this is now in 452R.

Wheeler R.F. [83] 'A survey of Baire measures and strict topologies', Expositiones Math. 1 (1983) 97-190. [§435 *notes*, §437 *notes*.]

Index to volumes 1-4

Principal topics and results

The general index below is intended to be comprehensive. Inevitably the entries are voluminous to the point that they are often unhelpful. I am therefore preparing a shorter, better-annotated, index which will, I hope, help readers to focus on particular areas. It does not mention definitions, as the bold-type entries in the main index are supposed to lead efficiently to these; and if you draw blank here you should always, of course, try again in the main index. Entries in the form of mathematical assertions frequently omit essential hypotheses and should be checked against the formal statements in the body of the work.

absolutely continuous real functions §225
—— as indefinite integrals 225E
absolutely continuous additive functionals §232
—— characterization 232B
—— on measure algebras 327B
actions of groups on topological spaces
—— and invariant measures 441C, 443P, 443Q, 443T, 449A
—— inducing actions on measure algebras and function spaces 443C, 443G, 444F
additive functionals on Boolean algebras §326, §327, §362
—— dominating or subordinate to a given functional 391E, 391F
—— on $\mathcal{P}I$ §464
almost continuous functions §418
—— and measurable functions 418E, 418J, 451S
—— and image measures of Radon measures 418I
amenable group §449
analytic spaces §423, §433
—— K-analytic spaces with countable networks 423C
—— and Souslin's operation 423E
angelic spaces §462
Archimedean Riesz spaces §353
associate norm (on a dual function space) §369
atomless measure spaces
—— have elements of all possible measures 215D
automorphisms and automorphism groups
—— of Boolean algebras §381, §382, §384
—— —— automorphisms as products of involutions 382M
—— —— normal subgroups of automorphism groups 382R, 383I
—— —— isomorphisms of automorphism groups 384D, 384E, 384J, 384M
—— of measure algebras §383, §385, §386, §387, §388, 493H

Baire measures §435
Banach lattices §354
—— order-bounded linear operators are continuous 355C
—— duals 356D
Banach-Ulam problem 363S
band algebra in a Riesz space 352Q
barycenter of a measure on a locally convex space §461
—— and convex functions 461C
—— existence of barycenters of given measures 461D, 461E, 461G
—— existence of measures with given barycenters 461H, 461K, 461M, 461N
Becker-Kechris theorem (on Borel measurable actions of Polish groups) 424H
Bernoulli shifts §387
—— calculation of entropy 385R
—— as factors of given homomorphisms (Sinaĭ's theorem) 387E, 387L
—— specified by entropy (Ornstein's theorem) 387I, 387K

Besicovitch's Covering Lemma (for balls in $\mathbb{R}^r$) 472B, 472C
Besicovitch's Density Theorem (for Radon measures on $\mathbb{R}^r$) 472D
biduals of Riesz spaces 356F, 356I
Bochner's theorem (positive definite functions are Fourier-Stieltjes transforms/characteristic functions) 445N
Boolean algebras Chap. 31
Boolean homomorphisms §312
—— between measure algebras §324
—— induced by measurable functions 324A
—— continuity and uniform continuity 324F
—— when measure-preserving 324K
—— represented by measurable functions 343B, 344B, 344E
Boolean rings §311
Borel measures §434
Borel sets in $\mathbb{R}^r$ 111G
—— and Lebesgue measure 114G, 115G, 134F
bounded variation, real functions of §224
—— as differences of monotonic functions 224D
—— integrals of their derivatives 224I
—— Lebesgue decomposition 226C
Brownian motion 455C
—— as a Radon measure on $C([0,\infty[)$ 455D
Cantor set and function 134G, 134H
capacity 432I, 432J
Carathéodory's construction of measures from outer measures 113C
Carleson's theorem (Fourier series of square-integrable functions converge a.e.) §286
Cauchy's Perimeter Theorem 475S
Central Limit Theorem (sum of independent random variables approximately normal) §274
—— Lindeberg's condition 274F, 274G
change of measure in the integral 235M
change of variable in the integral §235
—— $\int J \times g\phi \, d\mu = \int g \, d\nu$ 235A, 235E, 235L
—— finding J 235O;
—— —— $J = |\det T|$ for linear operators T 263A; $J = |\det \phi'|$ for differentiable operators ϕ 263D
—— —— —— when the measures are Hausdorff measures 265B, 265E
—— when ϕ is inverse-measure-preserving 235I
—— $\int g\phi \, d\mu = \int J \times g \, d\nu$ 235T
characteristic function of a probability distribution §285
—— sequences of distributions converge in vague topology iff characteristic functions converge pointwise 285L
Choquet's theorem (analytic sets are capacitable) 432J
Choquet's theorem (on measures on sets of extreme points) 461K
closed subalgebra of a measure algebra 323H, 323J
—— classification theorem 333H, 333K
—— defined by a group of automorphisms 333R
compact measure space §342, §343, §451
—— and representation of homomorphisms between measure algebras 343B
Compactness Theorem (for sets with bounded perimeter) 474S
complete measure space §212
completion of a measure 212C *et seq.*
concentration of measure 264H, §476, §492
conditional expectation
—— of a function §233
—— as operator on $L^1(\mu)$ 242J

construction of measures
—— image measures 112E
—— from outer measures (Carathéodory's method) 113C
—— subspace measures 131A, 214A
—— product measures 251C, 251F, 251W, 254C
—— from inner measures 413C
—— extending given functionals or measures 413I, 413J, 413O
—— —— yielding a Borel measure 435C
—— —— yielding a quasi-Radon measure 415K
—— —— yielding a Radon measure 416J, 416M, 432D, 435B
—— dominating given functionals 413S
—— τ-additive product measures 417C, 417E
—— as pull-backs 132G, 418L
—— as projective limits of Radon measures 418M
—— from integrals §436
—— —— from sequentially smooth functionals 436D
—— —— from smooth functionals 436H
—— —— yielding Radon measures (Riesz' theorem) 436J, 436K
—— of invariant measures 441C, 441E, 441H, 448P
continued fractions 372M *et seq.*
Control Measure Problem §393
convergence theorems (B.Levi, Fatou, Lebesgue) §123
convergence in measure (linear space topology on L^0)
—— on $L^0(\mu)$ §245
—— on $L^0(\mathfrak{A})$ §367
—— when Hausdorff/complete/metrizable 245E, 367N
—— and positive linear operators 367P
—— and pointwise compact sets of measurable functions §463, 465G
convex functions 233G *et seq.*, §461
Convex Isoperimetric Theorem 475T
convolution of functions
—— (on $\mathbb{R}^r$) §255, 473D, 473E
—— (on general topological groups) §444
—— $\int h \times (f * g) = \int h(x+y)f(x)g(y)dxdy$ 255G, 444O
—— $f * (g * h) = (f * g) * h$ 255J, 444O
convolution of measures
—— (on $\mathbb{R}^r$) §257
—— (on general topological groups) §444
—— $\int h\, d(\nu_1 * \nu_2) = \int h(x+y)\nu_1(dx)\nu_2(dy)$ 257B, 444C
—— of absolutely continuous measures 257F, 444Q
convolution of measures and functions 444H, 444J
countable sets 111F, 1A1C *et seq.*
countable-cocountable measure 211R
countably compact measures §451, §452
—— and disintegrations 452I, 452M
—— and inverse-measure-preserving functions 452R
counting measure 112Bd

Dedekind (σ)-complete Boolean algebras §314
—— Riesz spaces §353
Dedekind completion of a Boolean algebra 314T
differentiable functions (from $\mathbb{R}^r$ to $\mathbb{R}^s$) §262, §263
direct sum of measure spaces 214K

disintegration of measures §452
—— of one Radon measure over another, using a strong lifting to concentrate on fibers 453K
—— of Poisson point processes 495I
—— of symmetric measures on product space 459E, 459G
distribution of a finite family of random variables §271
—— as a Radon measure 271B
—— of $\phi(\boldsymbol{X})$ 271J
—— of an independent family 272G
—— determined by characteristic functions 285M
—— of an infinite family of random variables 454J
distributive laws in Boolean algebras 313B
—— in Riesz spaces 352E
divergence of a vector field §474
Divergence Theorem 475N, 484N
Doob's Martingale Convergence Theorem 275G
duals
—— of topological groups §445
—— of Riesz spaces §356, §362, 369C, 369J
—— of Banach lattices 356D
Duality Theorem (for abelian locally compact Hausdorff groups) 445U
Dye's theorem (on the full subgroup generated by a measure-preserving automorphism) 388K, 388L

effectively regular measure 491N
entropy (of a partition or a function) §385, §386
—— calculation (Kolmogorov-Sinaĭ theorem) 385P; (Bernoulli shifts) 385R
equidistributed sequences §491
Ergodic Theorem §372
—— (Pointwise Ergodic Theorem) 372D, 372E
—— (Maximal Ergodic Theorem) 372C
essential boundary (of a set in $\mathbb{R}^r$) §475
exchangeable random variables 459B, 459C
exhaustion, principle of 215A
extended real line §135
extension of measures 413K, 413O, 433J, 435C, 442Yc, 464D
—— yielding quasi-Radon measures 415L, 415M, 415N
—— yielding Radon measures 416F, 416M, 416N, 416O, 416P, 416Q, 432D, 432F, 433I, 435B
extension of order-continuous positive linear operators 355F, 368B, 368M
extremely amenable topological group §493

Fatou's Lemma ($\int \liminf \leq \liminf \int$ for sequences of non-negative functions) 123B
Federer exterior normal 474Q
Féjer sums (running averages of Fourier sums) converge to local averages of f 282H
—— uniformly if f is continuous 282G
de Finetti's theorem 459C
Fourier series §282
—— norm-converge in L^2 282J
—— converge at points of differentiability 282L
—— converge to midpoints of jumps, if f of bounded variation 282O
—— and convolutions 282Q
—— converge a.e. for square-integrable function 286V
Fourier transforms
—— on $\mathbb{R}$ §283, §284
—— on abelian topological groups §445
—— formula for $\int_c^d f$ in terms of $\hat{f}$ 283F
—— and convolutions 283M, 445G

—— as a multiplicative operator 445K
—— in terms of action on test functions 284H *et seq.*
—— of square-integrable functions 284O, 286U, 445R
—— inversion formulae for differentiable functions 283I; for functions of bounded variation 283L; for positive definite functions 445P
—— $\hat{f}(y) = \lim_{\epsilon\downarrow 0} \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-iyx} e^{-\epsilon x^2} f(x)dx$ a.e. 284M
free products of Boolean algebras §315
—— universal mapping theorem 315I
free products of measure algebras §325
—— universal mapping theorems 325D, 325J
Fremlin's Alternative (for sequences of measurable functions) 463H
Fubini's theorem §252
—— $\int f d(\mu \times \nu) = \iint f(x,y)dxdy$ 252B
—— when both factors σ-finite 252C, 252H
—— for characteristic functions 252D, 252F
—— for τ-additive product measures 417H
function spaces §369, §374, §376
Fundamental Theorem of the Calculus ($\frac{d}{dx}\int_a^x f = f(x)$ a.e.) §222, 483I; ($\int_a^b F'(x)dx = F(b) - F(a)$) 225E, 483R

Gagliardo-Nirenberg-Sobolev inequality 473H
gauge, gauge integral §481, §482
Gaussian distributions §456
—— are τ-additive 456K

Haar measure (on topological groups) Chap. 44
—— construction 441E
—— uniqueness 442B
—— action of the group on the measure algebra 443C
—— —— and on L^0 443G
—— derivable from Haar measure on locally compact groups 443L
—— completion regular 443M
—— has a translation-invariant lifting 447J
—— —— which is a strong lifting 453B
Hahn decomposition of a countably additive functional 231E
—— on a Boolean algebra 326I
Hahn-Banach property *see* Nachbin-Kelley theorem (363R)
Hardy-Littlewood Maximal Theorem 286A
Hausdorff measures (on $\mathbb{R}^r$) §264
—— are topological measures 264E
—— r-dimensional Hausdorff measure on $\mathbb{R}^r$ a multiple of Lebesgue measure 264I
—— on general metric spaces §471
—— Increasing Sets Lemma 471G
—— inner regularity properties 471D, 471I, 471S
—— density theorem 471P
—— need not be semi-finite 439H
—— $(r-1)$ dimensional measure on $\mathbb{R}^r$ 265F-265H, Chap. 47
Henry's theorem (on extending measures to Radon measures) 416M
Henstock integral §483

image measures 112E
—— of Radon measures 418I
—— of countably compact measures 452R
indefinite integrals
—— differentiate back to original function 222E, 222H, 483I

—— to construct measures §234
—— Saks-Henstock indefinite integrals 482B-482D, 484J
independent random variables §272
—— joint distributions are product measures 272G
—— limit theorems §273, §274
inner measures 413A *et seq.*
inner regularity of measures §412
—— (with respect to closed sets) Baire measures 412D; Borel measures on metrizable spaces 412E
—— (with respect to compact sets) Lebesgue measure 134F; Radon measures §256, §416
—— in complete locally determined spaces 412J
—— in product spaces 412S, 412U, 412V
—— and Souslin's operation 431D
integral operators §376
—— represented by functions on a product space 376E
—— characterized by action on weakly convergent sequences 376H
—— into M-spaces or out of L-spaces 376M
—— and weak compactness 376P
—— disintegrated 376S
integration of real-valued functions, construction §122
—— as a positive linear functional 122O
—— —— acting on $L^1(\mu)$ 242B
—— by parts 225F
—— characterization of integrable functions 122P, 122R
—— over subsets 131D, 214E
—— functions and integrals with values in $[-\infty,\infty]$ §133
—— measures derived from integrals §436
integration of families of measures §452
invariant means on topological groups 449E, 449I
invariant measures §441, §448
—— on measure algebras 394P
—— on locally compact spaces, under continuous group actions 441C, 443P, 443Q, 443T
—— on locally compact groups (Haar measures) 441E
—— on locally compact metric spaces, under isometries 441H
—— on Polish groups 448P
isoperimetric theorems 474L, 475T

Jensen's inequality 233I-233J
—— expressed in $L^1(\mu)$ 242K

Kakutani's theorem (on the representation of L-spaces as L^1-spaces) 369E
Kolmogorov's extension theorem (for a consistent family of probability measures on finite subproducts) 454D
Kolmogorov-Sinaĭ theorem (on the entropy of a measure-preserving homomorphism) 385P
Komlós' subsequence theorem 276H
Kwapien's theorem (on maps between L^0 spaces) 375I

Lebesgue's Density Theorem (in $\mathbb{R}$) §223
—— $\lim_{h\downarrow 0}\frac{1}{h}\int_x^{x+h} f = f(x)$ a.e. 223A
—— $\lim_{h\downarrow 0}\frac{1}{2h}\int_{x-h}^{x+h}|f(x-y)|dy = 0$ a.e. 223D
—— (in $\mathbb{R}^r$) 261C, 261E
—— (for Hausdorff measure) 471P
—— (in topological groups with B-sequences) 447D
Lebesgue measure, construction of §114, §115
—— further properties §134
—— characterized as measure space 344I

Lebesgue's Dominated Convergence Theorem ($\int \lim = \lim \int$ for dominated sequences of functions) 123C, 367J
B.Levi's theorem ($\int \lim = \lim \int$ for monotonic sequences of functions) 123A; ($\int \sum = \sum \int$) 226E
lifting (of a measure)
—— complete strictly localizable spaces have liftings 341K
—— translation-invariant liftings on $\mathbb{R}^r$ and $\{0,1\}^I$ §345
—— respecting product structures §346
—— strong liftings §453
—— Haar measures have translation-invariant liftings 447J
Lipschitz functions §262
—— differentiable a.e. 262Q
localizable measure space
—— assembling partial measurable functions 213N
—— which is not strictly localizable 216E
locally finite perimeter (for sets in $\mathbb{R}^r$) §474, §475
locally uniformly rotund norm §467
Loomis-Sikorski representation of a Dedekind σ-complete Boolean algebra 314M
lower density (on a measure space)
—— strictly localizable spaces have lower densities 341H
—— respecting a product structure 346G
Lusin's theorem (measurable functions are almost continuous), 418J
—— (on $\mathbb{R}^r$) 256F
—— (on Radon measure spaces) 451S
Lusin's theorem (injective continuous images of Polish spaces are Borel) 423I

Maharam's theorem
—— (homogeneous probability algebras of Maharam type κ are isomorphic) 331I
—— —— to measure algebra of $\{0,1\}^\kappa$) 331L
—— classification of localizable measure algebras 332J
Maharam type
—— (calculation of) 332S
—— —— for measure algebras of qproduct spaces 334A, 334C
—— relative to a subalgebra 333E
Markov processes §455
—— as Baire measures on $\prod_{t\in T} X_t$ defined from conditional distributions 455A
martingales §275
—— L^1-bounded martingales converge a.e. 275G, 367K
—— when of form $\mathbb{E}(X|\Sigma_n)$ 275H, 275I
measurable algebra §391
—— characterized by weak (σ,∞)-distributivity and existence of strictly positive additive functional 391D; by existence of uniformly exhaustive strictly positive Maharam submeasure 392J
—— Control Measure Problem §393
measurable envelopes
—— elementary properties 132E
—— existence 213L
measurable functions
—— (real-valued) §121
—— —— sums, products and other operations on finitely many functions 121E
—— —— limits, infima, suprema 121F
—— into general topological spaces §418
—— and almost continuous functions 418E, 418J, 451S
—— as selectors 423M, 433F-433G
measurable sets
—— and Souslin's operation 431A

measure algebras
—— properties related to those of measure spaces 322B
—— relationships between elementary properties 322C
—— satisfying the countable chain condition 322G
—— topologies and uniformities on §323, §324; uniqueness of topology and uniformity 324H
measure-free cardinals §438
measure-preserving Boolean homomorphisms
—— extension from a closed subalgebra 333C
modular function (of a topological group carrying Haar measures) 442I
—— and calculation of integrals 442K
—— of a subgroup 443Q
—— of a quotient group 443S
Monotone Class Theorem 136B
monotonic functions
—— are differentiable a.e. 222A

Nadkarni-Becker-Kechris theorem (on measures invariant under Polish group actions) 448P
narrow topologies on spaces of signed measures 437J *et seq.*
von Neumann-Jankow selection theorem 423N
non-measurable set (for Lebesgue measure) 134B
non-paradoxical group (of automorphisms of a Boolean algebra) §394, §448
—— characterizations 394D, 448D
—— invariant functionals 394O, 394P, 395B, 448P

order-bounded linear operators §355
order-closed ideals and order-continuous Boolean homomorphisms 313P
order-continuous linear operators §355
order*-convergence of a sequence in a lattice §367
order-dense sets in Boolean algebras 313K
—— in Riesz spaces 352N
Ornstein's theorem (on isomorphism of Bernoulli shifts with the same entropy) 387I, 387K
outer measures constructed from measures §132
—— elementary properties 132A
outer regularity of Lebesgue measure 134F

partially ordered linear spaces §351
perfect measure space 342K *et seq.*, §451
—— and pointwise compact sets of measurable functions 463I
perimeter measure (for sets in $\mathbb{R}^r$) §474, 475G
Pfeffer integral §484
Plancherel Theorem (on Fourier series and transforms of square-integrable functions) 282K, 284O, 445R
Poincaré's inequality 473K
pointwise convergence (in a space of functions) §462, §463, 465D, 465G
—— (in an isometry group) 441G
Poisson point processes §495
—— and disintegrations 495I
Poisson's theorem (a count of independent rare events has an approximately Poisson distribution) 285Q
product of two measure spaces §251
—— basic properties of c.l.d. product measure 251I
—— Lebesgue measure on $\mathbb{R}^{r+s}$ as a product measure 251M
—— more than two spaces 251W
—— Fubini's theorem 252B, 417H
—— Tonelli's theorem 252G, 417H
—— and L^1 spaces §253
—— continuous bilinear maps on $L^1(\mu) \times L^1(\nu)$ 253F

—— conditional expectation on a factor 253H
—— and measure algebras 325A *et seq.*
—— of τ-additive measures 417C; of quasi-Radon measures 417N; of Radon measures 417P
—— of compact, countably compact and perfect measures 451I
product of any number of probability spaces §254
—— basic properties of the (completed) product 254F
—— characterization with inverse-measure-preserving functions 254G
—— products of subspaces 254L
—— products of products 254N
—— determination by countable subproducts 254O
—— subproducts and conditional expectations 254R
—— and measure algebras 325I *et seq.*
—— having homogeneous measure algebras 334E
—— of separable metrizable spaces 415E; of compact metrizable spaces 416U
—— of τ-additive measures 417E; associative law 417J; of quasi-Radon measures 415E, 417O; of Radon measures 416U, 417Q
—— of compact, countably compact and perfect measures 451J
Prokhorov's theorem (on projective limits of Radon measures) 418M

quasi-Radon measures §415
—— are strictly localizable 415A
—— subspaces are quasi-Radon 415B
—— specification and uniqueness 415H
—— construction 415K
—— —— from smooth linear functionals 436H
—— products 415E, 417N, 417O
—— on locally convex spaces §466

Rademacher's theorem (Lipschitz functions are differentiable a.e.) 262Q
Radon measures, §416
—— on $\mathbb{R}^r$ §256
—— as completions of Borel measures 256C, 433C
—— indefinite-integral measures 256E, 416S
—— image measures 256G, 418I
—— product measures 256K, 416U, 417P, 417Q
—— extending given functionals or measures 416J, 416M-416Q, 432D
—— subspaces 416R
—— and Stone spaces of measure algebras 416V
—— and measurable functions 451S
—— as pull-backs 418L, 433D
—— and disintegrations 453K
—— Haar measures 441E; other invariant measures 441H, 448P
—— on locally convex spaces §466
Radon-Nikodým theorem (truly continuous additive set-functions have densities) 232E
—— in terms of $L^1(\mu)$ 242I
—— on a measure algebra 327D, 365E
rearrangements (monotonic rearrangements of measurable functions) §373, §374
regular open algebras 314P, §513
representation
—— of Boolean algebras *see* Stone's theorem (311E)
—— of Dedekind σ-complete Boolean algebras 314M
—— of measure algebras 321J
—— of homomorphisms between measure algebras §343, §344
—— of linear functionals as integrals §436
—— of partially ordered linear spaces 351Q

—— of Riesz spaces 352L, 353M, 368E *et seq.*, 369A
—— of Riesz space duals 369C
—— of L-spaces 369E
—— of M-spaces 354L
representations of topological groups 446B
Riesz representation theorem (construction of a Radon measure from an integral) 436J, 436K
Riesz spaces (vector lattices) §352
—— identities 352D, 352F, 352M
Saks-Henstock lemma 482B
—— indefinite integrals 482D, 484J
Shannon-McMillan-Breiman theorem (entropy functions of partitions generated by a measure-preserving homomorphism converge a.e.) 386E
signed measures 437C, 437H
simple product of Boolean algebras
—— universal mapping theorem 315B
—— of measure algebras 322K
Sinaĭ's theorem (on existence of Bernoulli partitions for a measure-preserving automorphism) 387E, 387L
Souslin's operation §421
—— on measurable sets §431
split interval 343J, 419L
stable set of functions §465
—— is relatively pointwise compact 465D
—— pointwise convergence and convergence in measure 465G
—— uniform strong law of large numbers 465M
—— in L^0 465P
—— in L^1 465R
—— R-stable set 465S
Stone space of a Boolean ring or algebra 311E *et seq.*
—— as topological space 311I
—— and Boolean homomorphisms 312P, 312Q
—— of a Dedekind complete algebra 314S
—— and the countable chain condition 316B
—— and weak (σ, ∞)-distributivity 316I
—— of a measure algebra 321J, 322N, 322Q
—— of a Radon measure space 416V
Stone-Weierstrass theorem §281
—— for Riesz subspaces of $C_b(X)$ 281A
—— for subalgebras of $C_b(X)$ 281E
—— for *-subalgebras of $C_b(X;\mathbb{C})$ 281G
—— for *-subalgebras of $C_0(X;\mathbb{C})$ 4A6B
strictly localizable measures
—— sufficient condition for strict localizability 213O
—— complete locally determined effectively locally finite τ-additive topological measures are strictly localizable 414J
strong law of large numbers ($\lim_{n\to\infty} \frac{1}{n+1}\sum_{i=0}^{n}(X_i - \mathbb{E}(X_i)) = 0$ a.e.) §273
—— when $\sum_{n=0}^{\infty} \frac{1}{(n+1)^2}\operatorname{Var}(X_n) < \infty$ 273D
—— when $\sup_{n\in\mathbb{N}} \mathbb{E}(|X_n|^{1+\delta}) < \infty$ 273H
—— for identically distributed X_n 273I
—— for martingale difference sequences 276C, 276F
—— convergence of averages for $\|\ \|_1$, $\|\ \|_p$ 273N
—— and functions on product spaces 465H
—— nearly uniformly on stable sets 465M
strong liftings §453

submeasure §392
subspace measures
—— for measurable subspaces §131
—— for arbitrary subspaces §214
surface measure in $\mathbb{R}^r$ §265
symmetric group 449Xc, 492H, 493Xc
symmetric measures on product spaces 459E, 459G

tagged-partition structures §481, §482
Talagrand's measure §464
Tamanini-Giacomelli theorem 484B
tensor products of L^1 spaces §253, 376C
Tonelli's theorem (f is integrable if $\iint |f(x,y)|dxdy < \infty$) 252G, 417H
topological groups chap. 44
—— amenable groups §449
—— duality theorem §445
—— extremely amenable groups §493
—— Haar measure §441, §442, §443
—— structure theory §446

uniformly exhaustive submeasures
—— and additive functionals 392F
uniformly integrable sets in L^1 §246
—— criteria for uniform integrability 246G
—— in L-spaces 354P *et seq.*
—— and convergence in measure 246J
—— and weak compactness 247C, 356Q
—— in dual spaces 356O, 362E
universally measurable sets and functions §434

vague topologies on spaces of signed measures 437J *et seq.*
Vitali's theorem (for coverings by intervals in $\mathbb{R}$) 221A
—— (for coverings by balls in $\mathbb{R}^r$) 261B
—— (in general metric spaces) 471O
—— (in topological groups with B-sequences) 447C

weak compactness in $L^1(\mu)$ §247
—— in L-spaces 356Q
—— in $C_0(X)$ 462E
weak topologies of locally convex spaces §466
weakly compactly generated normed spaces 467L
weakly (σ,∞)-distributive Boolean algebras §316
—— and measure algebras 322F, 391D
—— Riesz spaces 368Q
Weyl's Equidistribution Theorem 281N

c.l.d. version 213D *et seq.*
$C(X)$ §436, §462
$C_b(X)$ §436, §437
K-analytic spaces §422, §432
—— basic properties 422G
—— and Souslin-F sets 422H
—— are capacitable 432B, 432J
K-countably determined spaces 467H *et seq*
L-space 354N *et seq.*, §371
$L^0(\mu)$ (space of equivalence classes of measurable functions) §241
—— as Riesz space 241E

$L^0(\mathfrak{A})$ (based on a Boolean algebra) §364, §368, §369, §375
—— as a quotient of a space of functions 364D
—— algebraic operations 364E
—— calculation of suprema and infima 364M
—— linear operators induced by Boolean homomorphisms 364R
—— *when $\mathfrak{A}$ is a regular open algebra 364U
—— —— *of a compact extremally disconnected space 364W
—— as the domain of a linear operator 375A, 375C
—— positive linear operators between L^0 spaces can be derived from Riesz homomorphisms 375I
$L^1(\mu)$ (space of equivalence classes of integrable functions) §242
—— norm-completeness 242F
—— density of simple functions 242M
—— (for Lebesgue measure) density of continuous functions and step functions 242O
$L^1(\mathfrak{A}, \bar{\mu})$ (based on a measure algebra) §365
—— related to $L^1(\mu)$ 365B
—— as L-space 365C, 369E
—— linear operators induced by Boolean homomorphisms 365H, 365O, 365P
—— duality with L^∞ 365M
—— universal mapping theorems 365I, 365K
—— stable sets 465R
$L^p(\mu)$ (space of equivalence classes of pth-power-integrable functions, where $1 < p < \infty$) §244
—— is a Banach lattice 244G
—— has dual $L^q(\mu)$, where $\frac{1}{p} + \frac{1}{q} = 1$ 244K
—— and conditional expectations 244M
$L^p(\mathfrak{A})$ (based on a Boolean algebra) §366
—— related to $L^p(\mu)$ 366B
—— as Banach lattice 366C
—— linear operators induced by Boolean homomorphisms 366H
$L^\infty(\mu)$ (space of equivalence classes of bounded measurable functions) §243
—— duality with L^1 243F-243G
—— norm-completeness 243E
—— order-completeness 243H
$L^\infty(\mathfrak{A})$ (where $\mathfrak{A}$ is a Boolean algebra) §363
—— universal mapping theorems 363E
—— linear operators induced by Boolean homomorphisms 363F
—— order-completeness 363M
—— Nachbin-Kelley theorem (generalized Hahn-Banach theorem) 363R
ℓ^∞ and its dual §464
$\mathrm{L}^\sim(U; V)$ (space of order-bounded linear operators) §355, 371B, 371C
$\mathrm{L}^\times(U; V)$ (space of differences of order-continuous linear operators) §355, 376E
M-space 354G *et seq.*
$S(\mathfrak{A})$ (space of 'simple' functions corresponding to a Boolean ring $\mathfrak{A}$) §361
—— universal mapping theorems 361F-361I
—— linear operators induced by ring homomorphisms 361J
—— dual spaces §362
$\mathcal{T}$, $\mathcal{T}^{(0)}$, $\mathcal{T}^\times$ (classes of operators which are norm-reducing for every $\| \|_p$) 371F-371G, §372, §373, §374
usco-compact relations §422

σ-algebras of sets §111
—— generated by given families 136B, 136G
σ-finite measures 215B
τ-additive measures §414, §417
—— and semi-continuous functions 414A, 414B
—— products

—— —— of two τ-additive measures 417C
—— —— of many τ-additive probability measures 417E
—— on quasi-dyadic spaces 434Q

$\{0,1\}^\kappa$
—— usual measure is (Maharam) homogeneous with Maharam type κ 331K; is homogeneous in strict sense 344L; is a completion regular Radon measure 416U

General index

References in **bold** type refer to definitions; references in *italics* are passing references. Definitions marked with > are those in which my usage is dangerously at variance with that of some other author.

Abel's theorem 224Yi
Abel-Poisson kernel **282Yg**

Banach-Tarski paradox 449Yg
Banach-Ulam problem 232Hc, 326 *notes*, 363S, 376Yg, 439J, 439L; *see also* measure-free cardinal (**438A**)
band in a Riesz space **352O**, 352P-352V, 352Xe, 352Xf, 352Xj, 353B, 353C, 353E, 353H, 353I, 354Bd, 354O, 355H, 355I, 356B, 356L, 362B, 362C, 362Xf-362Xi, 364Xn, *364Xo*, 414Yb, 436L, 436Xr, 437A, 437F, 437Xq; *see also* complemented band, complement of a band, principal band, projection band
band algebra (of an Archimedean Riesz space) **353B**, 353D, 356Yc, 356Yd, 361Yc, 362Ya, 362Yb, 365S, *365Xm*, 366Xb, 368E, 368R; *see also* complemented band algebra (**352Q**), projection band algebra (**352S**)
band projection **352R**, 352Sb, 352Xm, 355Yh, 356C, 356Xe, 356Xf, 356Yb, 362B, 362D, 362Ye, 362Yi
barycenter **461Aa**, 461B-461E, 461G, 461H, 461J, 461K, 461M, 461N, 461Xb-461Xd, 461Xj, 461Yb, *464Xb*
base for a filter **4A1Ia**
base for a topology **3A3M**, 4A2Ba, 4A2Fc, 4A2Lg, 4A2O, 4A2Pa
—— *see also* π-base (**4A2A**)
base of neighbourhoods **4A2A**, 4A2Gd
basically disconnected topological space 314Yf
basis *see* Hamel basis (**4A4Aa**), orthonormal basis (**4A4Ja**)
Becker-Kechris theorem 424H; *see also* Nadkarni-Becker-Kechris theorem
A.Bellow's problem 463Za
Bernoulli partition **387A**, 387B, 387D-387H, 387J
—— shift **385Q**, 385R, 385S, 385Xi-385Xm, 386Xc, 387B, 387I, 387K, 387L, 387Xa, 387Xc, 387Ya
Berry-Esséen theorem 274Hc, 285 *notes*
Besicovitch's Covering Lemma 472A-472C, 472Yb
Besicovitch's Density Theorem 472D, 472Ye
bidual of a normed space (U^{**}) 342Yc, 356Xh, *3A5Ga*, 437Ib, 4A4If; *see also* order-continuous bidual
bidual of a topological group 445E, 445O, 445U
Bienaymé's equality 272R
bilateral uniformity on a topological group 443H, 443I, 443K, 443Xk, 443Yd, 444Xs, *445Ab*, 445E, 445Ya, 449Xh, 493Xb, **4A5Hb**, 4A5M-4A5O

bilinear map §253 (**253A**), 255Xb, 363L, 376B, 376C, 376Ya-376Yc, 436Yf, 437M, 437Xn, 437Ym, 444Sa, *482Xa*

Bipolar Theorem 4A4Eg

Bochner integral **253Yf**, 253Yg, 253Yi, 354Yl, 451Yf, 463Yb, *463Yc*, 483Yg

Bochner's theorem 285Xr, 445N, 445Xh, 445Xo

Boolean algebra Chap. 31 (**311Ab**), 363Xf; *see also* algebra of sets, complemented band algebra (**352Q**), Dedekind (σ-)complete Boolean algebra, measure algebra (**321A**), projection band algebra (**352S**), regular open algebra (**314Q**)

Boolean automorphism 363Ye, 366Yh, *374Yd*, 381C-381E, 381G, 381I, 381J, 381L, 381Q, 381Xc, 381Xf, 381Xg, 381Xn, 381Xo, 381Yb, 382A, 382B, 382D, 382E, 382G-382M, 382Xa, 382Xc, 382Xd, 384A, 388D, 388Xa, 388Ya, 394Ge, 394Ya, 395A, 424Xk, *442H*, 443Af; *see also* Borel automorphism, cyclic automorphism (**381R**), induced automorphism (**381M**), involution, measure-preserving Boolean automorphism, periodic automorphism (**381Bc**), von Neumann automorphism (**388D**), weakly von Neumann automorphism (**388D**)

Boolean homomorphism **312F**, 312G-312K, 312N, 312P-312T, 312Xe, 312Xg, 312Xj, *312Ya*, 313L-313N, 313P-313R, 313Xp, 313Yb, 314I, 314K, 314Xh, 316Yo, §324, *326Be*, *332Yc*, 343A, *352Ta*, 361Xd, 363F, 363Xb, 363Xc, 381B, 381H, 381Xj, *385K*; *see also* aperiodic Boolean homomorphism (**381Bd**), Boolean isomorphism, measure-preserving Boolean homomorphism, (sequentially) order-continuous Boolean homomorphism, periodic Boolean homomorphism (**381Bc**)

Boolean-independent subalgebras **315Xn**

Boolean isomorphism 312L, 314I, 332Xj, 344Yb, 366Yh

Boolean ring §311 (**311Aa**), §361

Boolean subalgebra *see* subalgebra of a Boolean algebra (**312A**)

'Boolean value' (of a proposition) *364Bb*

Borel algebra *see* Borel σ-algebra

Borel automorphism 419Xh

Borel-Cantelli lemma 273K

Borel constituent *see* constituent (**423P**)

Borel isomorphism 254Xs, 419Xh, 423Yc, 424C, 424D, **4A3A**

Borel lifting *345F*, *345Xg*, *345Yc*

Borel measurable function **121C**, 121D, 121Eg, 121H, 121K, **121Yf**, 134Fd, 134Xd, 134Yt, **135Ef**, 135Xc, 135Xe, 225H, 225J, *225Yf*, 233Hc, 241Be, 241I, 241Xd, 256M, 364I, 364J, 364Xg, 364Yd, 367Yo, *417Bb*, *418A*, 423G, 423Ib, 423O, 423Xi, 423Yc, *423Ye*, 433D, 434Xi, 437Jd, 437Yg, 471Xf, *443Jb*, *444F*, *444G*, *444Xg*, 466Xh, 476Xe, 493Yd, **4A3A**, 4A3C, 4A3Dc; *see also* Borel isomorphism

Borel measure **>411K**, 411Xf-411Xh, 412E, *412Xf*, 414L, 414Xj, 415C, 415D, 416F, 416H, 417Xc, 417Xd, 432Xc, 433C, §434, 435C, 435Xa-435Xd, 435Xf, 435Xg, 451Xi, 452Xa, 471S, 438I, 438S, 438Yc, 438Yj, 444E, 466H, 491Xw; (on $\mathbb{R}$) 211P, 216A, 341Lg, 343Xd, 345F; *see also* signed Borel measure (**437G**)

Borel-measure-compact (topological) space **434Ga**, 434H, 434I, 434Na, 434Xj, 434Xk-434Xn, 434Xu, 434Yg, 434Yj, 435Fd, 435Xk, 438J, 438Xk, 438Xo, 438Yd, *439P*

Borel-measure-complete (topological) space **434Gb**, 434I, 434Ka, 434N, 434Xj, 434Xk-434Xn, 434Xr, 434Xs, 434Xu, 438Jc, 438M, 438Xk, 438Xo, 438Ye, *439P*, 439Xh, *466H*

Borel sets in $\mathbb{R}$, $\mathbb{R}^r$ **111G**, *111Yd*, 114G, 114Yd, 115G, 115Yb, *115Yd*, *121Ef*, *121K*, 134F, 134Xc, *135C*, 136D, 136Xj, *212Xc*, *212Xd*, 254Xs, 225J, 264E, 264F, 264Xb, *342Xi*, 364H, 364Yc, 474Xb, 475Cc;

—— in other topological spaces *411A*, *414Ye*, *418A*, 421Xj, 421Xk, 422J, 422Xf, *422Yc*, *422Yd*, 423E, 423I, 423K, *423L*, 423Xe, *424F*, *434Fc*, 443Jb, 443Xn, *444F*, *444Xg*, *451N*, **4A3A**, 4A3H-4A3J, 4A3Ya

Borel space *see* standard Borel space (**424A**)

Borel σ-algebra (of subsets of $\mathbb{R}^r$) **111Gd**, *114Yg*, *114Yh*, *114Yi*, 121J, 121Xd, 121Xe, 121Yb, *216A*, 251L, 364G, 382Yb, 439A;

—— (of other spaces) **135C**, 135Xb, **256Ye**, 271Ya, *314Ye*, *333Ya*, *411K*, 421H, 421Xe-421Xg, 421Xk, 421Xm, 423N, 423Xd, 423Yc, 424Xb, 424Xd-424Xf, 424Yb, *431Xa*, 433I, 434Eb, 435Xb, 435Xd, 437H, 443Jb, 443Yh, 452N, 461Xi, 466E, 466Yb, **4A3A**, 4A3C-4A3G, 4A3Kb, 4A3N, 4A3R, 4A3V, 4A3Xa, 4A3Xd; *see also* standard Borel space (**424A**), Effros Borel structure (**424Ya**)

boundary of a set in a topological space 411Gi, 411Yc, 474Xc, 475C, *475J*, 475S, 475T, 475Xa, **4A2A**, 4A2Bi; *see also* essential boundary (**475B**), reduced boundary (**474G**)

bounded bilinear map **253Ab**
bounded linear operator 253Ab, 253F, 253Gc, 253L, 253Xc, 253Yf, 253Yj, 253Yk, **2A4F**, 2A4G-2A4I, 2A5If, 355C, 3A5Ed, 466L, 466M, *466Yc*, 4A4Ib, *4A4La*; *see also* (weakly) compact linear operator (**3A5K**), order-bounded linear operator (**355A**), $\mathrm{B}(U;V)$ (**2A4F**)
bounded set (in $\mathbb{R}^r$) **134E**; (in a normed space) **2A4Bc**, 3A5H, 4A4Ka; (in a linear topological space) **245Yf**, 367Xw, **4A4B**; *see also* order-bounded (**2A1Ab**)
bounded support, function with *see* compact support (**4A2A**)
bounded variation, function of §224 (**224A**, **224K**), 225Cb, 225M, *225Oc*, *225Xh*, *225Xn*, 225Yc, 226Bc, 226C, 264Yp, 264Yb, 282M, 282O, 283L, 283Xj, 283Xk, *283Xm*, *283Xn*, *283Xq*, 284Xk, *284Yd*, 343Yc, 354Xt, 438Xp, 438Yi, 483Xg, 483Yd
bounding *see* ω^ω-bounding (**316Yg**)
box product of tagged-partition structures 481P
Breiman *see* Shannon-McMillan-Breiman theorem (386E)
Brownian motion **455C**, 455D, 455Yc, 456Xg; *see also* fractional Brownian motion (**456Ye**)

canonical outward-normal function **474G**, 474J, 474Q, 475O, 475P; *see also* Federer exterior normal (**474O**)
Cantor function **134H**, 134I, 222Xd, 225N, 226Cc, 262K, 264Xf, 264Yn
Cantor measure **256Hc**, 256Ia, 256Xk, 264Ym
Cantor set **134G**, 134H, 134I, 134Xe, 256Hc, 256Xk, 264J, 264Ym, 264Yn, 412Ya, 471Xg, 4A2Uc; *see also* $\{0,1\}^I$
cap (in a sphere) **476M**
capacity **432I**, 432J, 432Xf-432Xh; *see also* Hausdorff capacity (**471H**)
Carathéodory complete measure space *see* complete (**211A**)
Carathéodory's method (of constructing measures) 113C, 113D, 113Xa, 113Xd, 113Xg, 113Yc, 114E, 114Xa, *121Yc*, 132Xc, 136Ya, 212A, *212Xg*, 213C, 213Xa, 213Xb, 213Xd, 213Xf, *213Xg*, 213Xj, 213Ya, 214H, 214Xc, 216Xb, *251C*, *251Wa*, *251Xd*, *264C*, *264K*, 413Xd, 413Xl, 431C, *436Xc*, *436Xk*, 471C, 471Ya, 452Xi
cardinal **2A1Kb**, 2A1L, 3A1B-3A1E, 4A1A, 4A1B; *see also* measure-free cardinal (**438A**), regular cardinal (**4A1Aa**)
cardinal function (of a Boolean algebra) *see* cellularity (**332D**, Maharam type (**331F**)
—— (of a partially ordered set) *see* cofinality (**3A1F**)

countably full family of gauges **482Ia**, 482K, 482L
countably full group (of automorphisms of a Boolean algebra) **381Af**, 381I, 381Nh, 381Yb, 382H-382M
countably full local semigroup (of partial automorphisms of a Boolean algebra) §448 (**448A**)
countably generated σ-algebra 415Xi, 419Yb, 423Xd, 424Ba, 424Xb-424Xd, 424Xh-424Xj, 433I, 433J, 451F, 452Xl, 452Xn
countably K-determined *see* K-countably determined (**467H**)
countably metacompact (topological) space **434Yf**, 435Ya
countably paracompact (topological) space 435C, 435Xg, 435Xh, 435Ya, **4A2A**, 4A2Ff
countably separated (measure space, σ-algebra of sets) **343D**, 343E-343H, 343K, 343L, 343Xe, 343Xh, 343Xi, 343Yb, 343Ye, 343Yf, 344B, 344C, 344I, 344Xb-344Xd, 381Xm, 382Xd, 383Xa, 385V, 388A, 388B, 424E, 433B, 433Xe, *451Ad*, 452I, 453Xf
countably subadditive functional **392H**
countably tight (topological) space 423Ya, 434N, *434Yg*, 463E, 463Xd, **4A2A**, 4A2K, 4A2Ld
counting measure **112Bd**, *122Xd*, 122 *notes*, 211N, 211Xa, *213Xb*, 226A, 241Xa, 242Xa, 243Xl, 244Xi, 244Xn, 245Xa, 246Xc, 251Xb, 251Xh, *252K*, 255Yo, *264Db*, *324Xe*, 416Xb, *417Xi*, 442Ie, 445Xi, 445Xj, *481Xc*
covariance matrix (of a Gaussian distribution) **456Ac**, 456B, 456F, 456Xa, 456Xg
covariant measure *441 notes*
cover *see* measurable envelope (**132D**)
covering theorem 221A, 261B, 261F, *261Xc*, 261Ya, 261Yi, 261Yk, 472A-472C, 472Xb, 472Ya-472Yc
cozero set **3A3Pa**, 412Xg, *416Xi*, 421Xh, 443N, *443Yi*, 4A2Cb, 4A2F, 4A2Lc

cycle notation (for automorphisms of Boolean algebras) **381R**, 381S, 381T, 382Fb; *see also* pseudo-cycle (388Xc)

cyclic automorphism 381R; *see also* exchanging involution (**381R**)

cylinder (in 'measurable cylinder') **254Aa**, 254F, *254G*, *254Q*, 254Xa

cylindrical σ-algebra (in a locally convex space) *461D*, 461Xg, 461Xi, 464R, 466J, 466Xc, 466Xd, 466Xf, 491Yc, **4A3T**, 4A3U, 4A3V

Daniell integral 436Ya, 436Yb

Davies R.O. 325 *notes*

decimal expansions 273Xf

decomposable distribution *see* infinitely divisible

decomposable measure (space) *see* strictly localizable (**211E**)

decomposition (of a measure space) **211E**, *211Ye*, 213O, *213Xh*, 214Ia, 214K, 214M, *214Xi*, *322L*, 412I, 416Xe, 417Xe; *see also* disintegration (**452E**), Hahn decomposition of an additive functional (231F), Jordan decomposition of an additive functional (231F), Lebesgue decomposition of a countably additive functional (232I), Lebesgue decomposition of a function of bounded variation (§226)

decreasing rearrangement (of a function) **252Yp**; (of an element of $M^{0,\infty}(\mathfrak{A})$) §373 (**373C**), 374B-374D, 374J, 374L, 374Xa, 374Xj, 374Ya-374Yd

Dedekind complete Boolean algebra 314B, 314Ea, 314Fa, 314G, 314Ha, 314I, 314Ja, 314K, 314P, 314S, 314T, *314Va*, 314Xa, 314Xb, 314Xf, 314Xg, 314Xh, 314Yd, 314Yg, 314Yh, 315F, 315Yf, 316Fa, *316K*, 316Xt, 316Yi, *316Yn*, *331Yd*, 332Xa, *333Bc*, 352Q, 363Mb, 363P-363S, 364O, 368A-368D, 368K, 368M, *368Xe*, 375C, 375D, 375Xa, 375Xc, 375Ya, 381C, 381D, 381F, 381Ib, 381Xb, 381Xf, 381Xk, 381Yc, 382E, 382F, 382N, 382Q-382S, 382Xe-382Xj, 384D, 384J, 393A-393C, 393J, 393Xc-393Xf, 393Ya, 393Yc-393Yf 438Xc, *448Ya*

Dedekind complete partially ordered set *135Ba*, **314Aa**, 314B, 314Ya, 315De, 343Yc, 3A6C, 419L, 419Xf, 4A2R*see also* Dedekind complete Boolean algebra, Dedekind complete Riesz space

Dedekind complete Riesz space **241Fc**, 241G, 241Xf, 242H, 242Yc, 243H, 243Xj, 244L, 353G, 353I, 353Jb, 353K, 353Yb, 354Ee, §355, 356B, *356K*, *356Xj*, *356Ye*, 361H, 363Mb, 363P, 363S, 364O, 366C, 366G, 368H-368J, 371B-371D, 371Xd, 371Xe, 375J, 375Ya, 437Yj, 438Xd

Dedekind completion of a Boolean algebra 314T, **314U**, 314Xe, 314Yh, 315Yd, 322O, 361Yc, 365Xm, 366Xk, 368Xb, 384Lf, 384Xc, 391Xc; *see also* localization (**322P**)

Dedekind completion of a Riesz space 368I, **368J**, 368Xb, 368Yb, 369Xp

Dedekind σ-complete Boolean algebra 314C-314F, 314Hb, 314Jb, 314M, 314N, 314Xa, 314Xc, 314Ye, 314Yf, *315O*, *316C*, 316Fa, 316Hb, *316J*, *316Xg*, 316Yi, *316Yk*, *321A*, 324Yb, 324Yc, *326Fg*, 326I, 326O, 326P, 326Xc, 326Xi, 326Yf, 326Yo, 344Yb, 362Xa, 363Ma, 363P, 363Xh, 363Yh, §364, 367Xk, 368Yd, 375Yb, 381C, 381D, 381Ia, 381K-381N, 381Xb, 381Xk, 381Xp, 381Yb, 382D, 382E, 382G-382M, 382S, 382Xk, 382Xl, 382Ya, 382Yc, 392H, 392Xd, 392Xf, 392Xg, 393A, 393E, 393M, 393O-393Q, 393S, 393Xb, 393Yg-393Yi, 424Xd, *491Xo*

Dedekind σ-complete partially ordered set **314Ab**, 315De, 367Bf, 367Xb, 466G; *see also* Dedekind σ-complete Boolean algebra, Dedekind σ-complete Riesz space

Dedekind σ-complete Riesz space **241Fb**, 241G, 241Xe, 241Yb, 241Yh, 242Yg, 243H, 243Xb, 353G, 353H, 353J, 353Xb, 353Yc, *353Yd*, 354Xn, 354Yi, *354Yl*, 356Xc, 356Xd, 363M-363P, 364C, 364E

delta function *see* Dirac's delta function (**284R**)

delta system *see* Δ-system (**4A1D**)

De Morgan's laws 311Xf; *see also* distributive laws

dense set in a topological space 242Mb, 242Ob, 242Pd, 242Xi, 243Ib, 244H, 244Ob, 244Yi, 254Xo, 281Yc, **2A3U**, 2A4I, *313Xj*, 323Dc, 367O, **3A3E**, 3A3G, 3A3Ie, *3A4Ff*, 412N, 412Yc, 417Xu, *449Xg*, *493Xa*, *4A2Ma*, *4A2Ni*, *4A2Ua*; *see also* nowhere dense (**3A3Fa**), order-dense (**313J**, **352Na**), quasi-order-dense (**352Na**)

density (of a topological space) 331Ye, **331Yf**, 365Ya, 393Yf

density function (of a random variable) **271H**, 271I-271K, 271Xc-271Xe, 272T, 272Xd, 272Xj, 495P; *see also* Radon-Nikodým derivative (**232If**, **234B**)

density point **223B**, 223Xi, 223Yb, 481Q

density topology **223Yb**, 223Yc, 223Yd, **261Yf**, **414P**, 414R, 414Xk-414Xo, 414Xq, 414Yd-414Yh, 418Xl, 451Yq, 453Xg, 475Xe

density *see also* asymptotic density (**273G**, **491A**), Besicovitch's Density Theorem (472D), Lebesgue's Density Theorem (223A), lower density (**341C**)
derivate *see* lower derivate (**483H**), upper derivate (**483H**)
derivative of a function (of one variable) 222C, 222E, 222F, 222G, 222H, 222I, 222Yd, 225J, *225L*, *225Of*, *225Xc*, *226Be*, 282R; (of many variables) **262F**, 262G, 262P, 473B, 473Ya;*see also* gradient, partial derivative
derived set (of a set of ordinals) 4A1Bb; derived tree **421N**, 421O
determinant of a matrix 2A6A
determined *see* locally determined measure space (**211H**), locally determined negligible sets (**213I**)
determined by coordinates (in 'W is determined by coordinates in J') **254M**, 254O, 254R-254T, 254Xp, 254Xr, 311Xh, 325N, 325Xh, 415E, 417M, 417Xu, 456H, *481P*, 4A2Bg, 4A2Eb, 4A3Mb, 4A3N, 4A3Yb
Devil's Staircase *see* Cantor function (**134H**)
diagonal intersection (of a family of sets) **4A1Bd**, 4A1Ic
diamond *see* Jensen's $\diamondsuit$
Dieudonné's measure **411Q**, *411Xj*, 434Xf, 434Xx, 491Xm
differentiability, points of 222H, 225J
differentiable function (of one variable) 123D, *222A*, *224I*, *224Kg*, *224Yc*, *225L*, *225Of*, *225Xc*, *225Xn*, 233Xc, 252Yj, 255Xg, 255Xh, 262Xk, 265Xd, *274E*, 282L, 282Xs, 283I-283K, *283Xm*, 284Xc, 284Xk, 483Xh; (of many variables) **262Fa**, 262Gb, 262I, 262Xg, 262Xi, 262Xj, 473B, 473Cd, 484N, 484Xf; *see also* derivative
'differentiable relative to its domain' **262Fb**, 262I, 262M-262Q, 262Xd-262Xf, 262Yc, 263D, 263Xc, 263Xd, 263Yc, 265E, 282Xk
diffused measure *see* atomless measure (**211J**)
dilation **286C**
dimension *see* Hausdorff dimension (**264 notes**, **471Xe**)
Dini's theorem 436Ic
Dirac's delta function 257Xa, **284R**, 284Xn, 284Xo, 285H, 285Xp
direct image (of a set under a function or relation) 1A1B
direct sum of measure spaces **214K**, 214L, 214Xi-214Xl, 241Xg, 242Xd, 243Xe, *244Xg*, *245Yh*, 251Xh, 251Xi, 322Kb, 332C, 342Gd, 342Ic, 342Xn, *343Yb*, 411Xh, 412Xl, 414Xb, 415Xb, 416Xc, 451Xe, 451Yh
direct sum of σ-algebras 424Xa
direct sum of topological spaces **4A2A**, 4A2Qe; *see also* disjoint union topology (**4A2A**)
directed set *see* downwards-directed (**2A1Ab**), upwards-directed (**2A1Ab**)
Dirichlet kernel **282D**; *see also* modified Dirichlet kernel (**282Xc**)
disconnected *see* extremally disconnected (**3A3Ae**), basically disconnected
discrete *see* σ-metrically-discrete (**4A2A**)
discrete topology (**3A3Ah**), *416Xb*, *417Xi*, 436Xg, 439Cd, 439Xh, 442Ie, 445A, 445Xj, 449G, 449K, 449Xj, 449Xr, 449Xs, 449Yb, 4A2Ib, 4A2Qa
disintegration of a measure **452E**, 452F-452K, 452M-452Q, 452Xf-452Xh, 452Xk-452Xn, 453K, 453Xi, 453Ya, 455A, 455Ya, 459E-459G, 459Xc, 495H; *see also* consistent disintegration (**452E**)
disjoint family (of sets) **112Bb**; (in a Boolean ring) **311Gb**; (in a Riesz space) **352C**, 352Fb
disjoint sequence theorem 246G, *246Ha*, 246Yd, 246Ye, 246Yf, 246Yj, 354Rb, 356O, 356Xm
disjoint set (in a Boolean ring) **311Gb**; (in a Riesz space) **352C**
disjoint union topology **315Xe**, 411Xh, 412Xl, 414Xb, 415Xb, 416Xc, **4A2A**, 4A2Bb, 4A2Cb; *see also* direct sum of topological spaces
distribution *see* Schwartzian distribution, tempered distribution
distribution of a random variable 241Xc, 271E, 271F, 271Ga, 272G, 272S, 272Xe, 272Yc, 272Yf, 272Yg, 285H, 285Xg, 415Fb, *415Xq*, 454L; (of an element of $L^0(\mathfrak{A},\bar{\mu})$) **364Xd**, 364Xf, 367Xv, 373Xh; *see also* Cauchy distribution (**285Xm**), empirical distribution (**273 notes**), exponential distribution (**495P**), gamma distribution (**455Xe**), Poisson distribution (**285Xo**), relative distribution (**458C**)
—— of a finite family of random variables 271B, **271C**, 271D-271G, 272G, 272Ye, 272Yf, 285Ab, 285C, 285Mb, 454J, 454K, 456M, 459C
—— of an infinite family of random variables 454J-454M (**454K**), 454Xj; *see also* Gaussian distribution (**456Ab**
distribution function of a random variable **>271G**, 271L, 271Xb, 271Yb, 271Yc, 271Yd, 272Xe, 272Yc, 273Xg, 273Xh, 274F-274L, 274Xd, 274Xg, 274Xh, 274Ya, 274Yc, 285P, 495P

essential closure **475B**, 475C, 475Xb, 475Xc, 475Xe, 475Xf, 484B, *484K*, 484Ra, 484Ya

essential interior **475B**, 475C, *475J*, 475Xb-475Xf

essential supremum of a family of measurable sets **211G**, 213K, 215B, 215C; of a real-valued function **243D**, 243I, 376S, 376Xn, 443Gb, 444R, *492G*, *492Xa*, *492Xd*

essentially bounded function **243A**

Etemadi's lemma 272U

Euclidean metric (on $\mathbb{R}^r$) **2A3Fb**, *443Xx*

Euclidean topology §1A2, §2A2, **2A3Ff**, 2A3Tc

even function 255Xb, 283Yb, 283Yc

exchangeable family of random variables **276Xe**, *459B*, **459C**, 459Xa, 459Xb, 459Ya

exchanging involution **381Ra**, 381S, 382C, 382E, 382H, 382K, 382L, 382M, 382P, *382Ya*

exhaustion, principle of 215A, 215C, 215Xa, 215Xb, *232E*, 246Hc, 342B, 365 *notes*

exhaustive submeasure **392Bb**, 392C, 392Hc, 392Xb-392Xd, 393A-393C, 393H; *see also* uniformly exhaustive (**392Bc**)

expectation of a random variable **271Ab**, 271E, 271F, 271I, *271Xa*, 272Q, 272Xb, *272Xi*, 285Ga, *285Xo*; *see also* conditional expectation (**233D**)

exponential distribution **495P**, 495Xj, 495Xo, 495Xp

exponentially bounded group **449Xp**

exponentiation (in a Banach algebra) **4A6L**, 4A6M

extended Fatou norm §369 (**369F**), 376S, 376Xn, 376Yl, 415Yl; *see also* $\mathcal{T}$-invariant extended Fatou norm (**374Ab**), rearrangement-invariant extended Fatou norm (**374Eb**)

extended real line *121C*, §135

exterior *see* Federer exterior normal (**474O**)

extension of finitely additive functionals 391G, 413K, 413N, 413Q, 413S, 413Yd, 449L, 449Xt, 457A, 457C, 457D, 457Hc, 457Xb-457Xe, 457Ya

extension of measures 132Yd, 212Xk, 327Xf, 413O, 415L-415N, 415Yi, 416F, 416M, *416O*, 416P, *416Q*, 416Yb, 416Yc, 417A, *417C*, *417E*, 417Xa, 417Ya, 417Ye-417Yg, 432D, 432F, *432Ya*, 433I, 433J, 433Xf, *434A*, *434Ha*, *434Ib*, 434R, 435B, 435C, 435Xa-435Xd, 435Xg, 435Xj, *439A*, *439M*, *439O*, 449M, 454C-454F, *454Xa-454Xc*, 457E, 457G, *457Hc*, *457J*, 457Xa, 457Xf, 457Xg, 457Xk, *457Yc*, 458Xr, 464D, *466H*, 466Xd, *466Za*; *see also* completion (**212C**), c.l.d. version (**213E**)

extremally disconnected topological space 314S, 314Xj, 353Yb, 363Yc, 364W, 364Yk-364Ym, 368G, 368Yc, **3A3Ae**, 3A3Bd, 4A2Gh, 491Yg

extreme point of a convex set **353Yf**, 437P, 437Xp, 438Xl, 459Xd, 459Xe, 461O, 461P, 461Xb, 461Xe, 461Xk, 461Xl, 461Yd, 461Ye, **4A4G**; (of a compact set in a Hausdorff linear topological space) **461Xj**

—— set of extreme points 461K-461N, 461Xh-461Xi, 461Yb

extremely amenable topological group §493 (**493A**)

factor (of an automorphism of a Boolean algebra) **387Ac**, 387L, 387Xb
fair-coin probability 254J
faithful action 449De, **4A5Be**
faithful representation **446A**, 446N
Fatou's Lemma **123B**, 133K, 135G, 135Hb, 365Xc, 365Xd, 367Xf
Fatou norm on a Riesz space 244Yf, **354Da**, 354Eb, 354J, 354Xk, 354Xn, 354Xo, 354Ya, 354Ye, 356Da, 367Xg, 369G, 369Xe, 371B-371D, 371Xc, 371Xd; *see also* extended Fatou norm (**369F**)
favourable *see* weakly α-favourable (**451U**)
Federer exterior normal **474O**, 474P, 474Q, 475N, 475Xd, 475Xg, *484M*, 484N, 484Xf; *see also* canonical outward-normal function (**474G**)
Féjer integral **283Xf**, 283Xh-283Xj
Féjer kernel **282D**
Féjer sums **282Ad**, 282B-282D, 282G-282I, 282Yc
Feller, W. Chap. 27 *intro.*
fiber product **458La**, 458Xf
field (of sets) *see* algebra (**136E**)
filter **2A1I**, 2A1N, 2A1O, 2A5F, 464C, *464D*, *464Fc*, 4A1I, 4A2Ib; *see also* complete filter (**4A1Ib**), convergent filter (**2A3Q**), normal filter (**4A1Ic**), ultrafilter (**2A1N**)
filter base **4A1Ia**
fine (in 'δ-fine tagged partition') **481E**, 481G
finer topology **4A2A**
de Finetti's theorem 459C
finite-cofinite algebra **231Xa**, 231Xc, **316Yk**, 392Xc
finite-dimensional linear subspace 4A4Bk, 4A4Je
finite-dimensional representation **446A**, 446B, 446C, 446N, 446Xa, 446Xb, 446Ya, 446Yb, 491Yi
finite group 445Ye
finite intersection property **3A3D**, *434M*, 4A1Ia
finite perimeter (for sets in $\mathbb{R}^r$) **474D**, 475Mb, 475Q, 484B, 484C, 484F, 484Xf
finite rank operators *see* abstract integral operators (**376D**)
finitely additive functional on an algebra of sets 136Xg, 136Ya, 136Yb, **231A**, 231B, 231Xb-231Xe, 231Ya-231Yh, 232A, 232B, 232E, 232G, 232Ya, 232Ye, 232Yg, 243Xk, 327C, 413H, 413K, 413N, 413P, 413Q, 413S, 413Xl, 413Xm, 413Xp, 416N-416Q, 416Xl, 416Xm, 416Xr, 471Q, 449J, 449Xr, 457A-457D, *482G*, *482H*, *493D*; *see also* countably additive, completely additive
finitely additive function(al) on a Boolean algebra **326A**, 326B-326D, 326Fa, 326G, 326Kg, 326Xa-326Xc, 326Xe, 326Xg, 326Xi, 326Yt-326Yd, 326Yg-326Yj, **326Yk**, 326Yl-326Yn, 326Yq, 326Yr, 327B, 327C, 331B, 361Xa-361Xc, 391D-391G, 391I, 391J, *391N*, 393Be, 393C, 393Xi, 394N, 394O, 413Xo, 416Q, 481Xh, 491Xy; *see also* chargeable Boolean algebra (**391X**), completely additive functional (**326J**), countably additive functional (**326E**)
finitely additive function(al) on a Boolean ring **361B**, 361C, 361E-361I, 365Eb
finitely additive measure **326A**
finitely full subgroup **381Xg**
first category *see* meager (**3A3Fb**)
first-countable topological space 434R, *434Xx*, 434Yk, 438S, 439K, 439Xf, 452Xa, *462Xa*, 462Xc, **4A2A**, 4A2K, 4A2Ld, 4A2Sb, 4A5Q
First Separation Theorem (of descriptive set theory) 422I, 422Xd, 422Yc
fixed-point subalgebra (in a Boolean algebra) **312T**, 313Xq, 333Q, 333R, 361Xk, 364Xv, 372Pa, 386B, 386Xa, 381P, 381Xj, 381Xp, 388L, **394G**, 394H, 394I, 394K-394N, 394P, 394Xb-394Xf, 394Yb, 394Yc
fixed point on compacta property *see* extremely amenable (**493A**)
Fodor's theorem *see* Pressing-Down Lemma (**4A1Cc**)
Fourier coefficients **282Aa**, 282B, 282Cb, 282F, 282I, 282J, 282M, 282Q, 282R, 282Xa, 282Xg, 282Xq, 282Xt, 282Ya, 283Xu, 284Ya, 284Yg
Fourier's integral formula **283Xm**
Fourier series *121G*, §282 (**282Ac**)

—— (in 'μ measures E', 'E is measured by μ') **>112Be**

measure algebra 211Yb, 211Yc, vol. 3 (**321A**), 448Xj, 448Xk, 493H, 495J, 495Xf, 495Xh; isomorphic measure algebras 331I, 331L, 332B, 332C, 332J, 332K, 332P, 332Q, 332Ya, 332Yb

measure algebra of a measure space 321H-321K (**321I**), 322B, 322N, *327C*, 412N, 414A, 415L, *416C*, *416W*, 418T, 441Ka, 441Yk, 474 *notes*, 493G; *see also* Haar measure algebra (**442H**), usual topology on a measure algebra (**323A**)

measure-algebra topology §323 (**323A**), 324F-324H, *324K*, 324Xb, *324Xc*, 327B, 327C, 365Ea, 367R, 367Xs, 367Yo, 411Yc, 412N, 443Aa, 443C, 444Fc, 444Yd, 448Xj, 493E, 494A; *see also* strong measure-algebra topology (**323Ae**)

measure-algebra uniformity **323A**, 323B-323D, 323G, 324F, 324H, 327B, 443Aa

measure-compact (topological) space **435D**, 463F-463H, 435Xb, 435Xh, 435Xi, 435Xk, 435Yb, 436Xf, 436Xg, 438Jb, 438Xk, *439P*, 439Q, 454Pa, 454Xm; *see also* strongly measure-compact (**435Xk**), Borel-measure-compact (**434Gb**)

measure-free cardinal **438A**, 438B, 438C, 438I, 438R, 438S, 438Xa-438Xe, 438Xh, 438Xj, 438Xn-438Xp, 438Yb-438Yf, 438Yi, 439Cd, *439J*, *439L*, 452Yb, 454Yb, 466F; *see also* Banach-Ulam problem

measure-free weight 438D-438H, 438J, 438M, 438S, 438Xf, 438Xg, 438Xi, 438Xk, 448Xi, 467Pb

measure metric (on a measure algebra) **323A**, *323Xg*, 324Yh, 448Xk, 493G, 493Yb

measure-preserving Boolean automorphism 332L, 333Gb, 333P-333R, 333Yc, 343Jc, 344C, 344E-344G, 344Xf, 364Xt, 372Xk, 372Xl, 372Yi, 373Yb, *374E*, 374G, 374L, 374Yc, 383D, 383Yc, 385P, 385Sb, 385Sf, 385Xg, 385Yd, 386N, 387B-387H, 387J, 387L, 388A, 388C, 388E-388H, 388J-388L, 388Xa-388Xe, 388Yd, 395Xc; *see also* automorphism group of a measure algebra, two-sided Bernoulli shift (**385Qb**)

measure-preserving Boolean homomorphism **324I**, 324J-324P, 324Xd, 324Xe, 324Yf, 324Yh, 325C, 325D, 325I, 325J, 325Xd, *327Xa*, 331D, 332L-332O, 332Q, 332Xm, 332Xn, 333C, 333D, 333F, 333Gb, 333Xc, 333Yd, 343B, 366Xf, 369Xm, 369Xn, 372G, *372H*, 372Xc, 373Bd, 373U, 373Xi, 383Yc, 385L-385Q, *385T*, 385V, 385Xf-385Xi, 385Xm, 385Xp, 385Yb-385Ye, 386A-386F, 386L, 386Xe, 386Xf, 386Ya-386Yc, 387A, 387B, *387F*, 458K, 491N, 491Xy; isomorphic measure-preserving Boolean homomorphisms **385Ta**; *see also* automorphism of a measure algebra, Bernoulli shift (**385Q**), measure-preserving ring homomorphism

measure-preserving function *see* inverse-measure-preserving function (**235G**), measure space automorphism, measure space isomorphism

measure-preserving ring automorphism 366L, 366Xh

measure-preserving ring homomorphism **361Ad**, 365O, 365Q, 366H, 366K, 366L, 366Xg, 366Xh, 366Yg, 369Xl, 372F; *see also* measure-preserving Boolean homomorphism

measure space §112 (**112A**), 113C, *113Yi*

measure space automorphism 255A, 255Ca, 255N, 255Ya, *255 notes*, 344C, 344E-344G, 344Xf, 345Ab, 345Xa, 346Xd, 385Sb, 419Xh, 443Xb, *482 notes*

measure space isomorphism 254K, 254Xj-254Xl, 255Ca, 255Mb, 344I, 344J, 344K, 344L, 344Xa-344Xc, 344Xe-344Xg, 344Yc, 433Xf, 433Yb

measure zero, cardinal of *see* measure-free cardinal (**438A**)

metacompact (topological) space 435Xj, 438J, 438Yd-438Yf, 451Ye, **>4A2A**, 4A2Fg; *see also* countably metacompact (**434Yf**), hereditarily metacompact (**4A2A**)

metric **2A3F**, 2A4Fb; *see also* entropy metric (**385Xq**), Euclidean metric (**2A3Fb**), Hamming metric (**492D**), Hausdorff metric (**246Yb**, **476A**), Huntingdon's metric **437Yi**, Lévy's metric (**274Ya**), measure metric (**323Ad**), pseudometric (**2A3F**), right-translation-invariant metric (**4A5Q**)

metric gauge *see* uniform metric gauge (**481E**)

metric outer measure 264Xb, **264Yc**, **471B**, 471C, 471Ya

metric space *224Ye*, *261Yi*, 316Yj, 3A4Fe, 3A4Ff, 3A4Hc, 434L, §471, 448Xi, 4A2Lg, 482E, *484Q*; *see also* complete metric space, isometry group (**441F**), metrizable space (**2A3Ff**)

metrically discrete *see* σ-metrically-discrete (**4A2A**)

metrically transitive transformation *see* ergodic inverse-measure-preserving function (**372Pb**)

metrizable (topological) space **2A3Ff**, 2A3L, 412E, 418B, 418F, 418G, 418Xc, *421Yb*, 423D, 434Ye, 437Yj, 437Yn, 438D-438G, 438I, 438Jc, 438Xk, 438Yc, 439Yd, 441Xm, 451Q-451S, 451Xm, 461K, 461N,

462Xa, *491Cg*, 491Xk, 4A2L, 4A2Nh, 4A3Kb, 4A4Cf; *see also* compact metrizable space, metric space, separable metrizable space, Polish space (**4A2A**)
—— linear topological space 462Yb, 466A, 466Xa, 466Xc, 466Xd, 4A3V; *see also* normed space
—— topological group 446Ec, 4A5Q-4A5S
—— uniformity **3A4Bc**, 445Ya
mid-convex function **233Ya**, 233Yd
minimal element in a partially ordered set **2A1Ab**
mixing inverse-measure-preserving function **372P**, 372Q, 372R, 372Xk, 372Xm-372Xo, 372Xq, 372Xr, 372Xu, 372Xv, 372Yh, 372Yl
mixing measure-preserving homomorphism 333P, 333Yc, **372P**, 372Q, 372R, 372Xk, 372Xl, 372Xp, 372Yl, 372Yn, 385Se, 387Xb, *388Yc*
mixture of distributions *459C*; *see also* disintegration (**452E**)
moderated set function **482Ib**, 482K, 482M, 482Xj, 482Xk, 482Yc
modified Dirichlet kernel **282Xc**
modular function (of a group carrying Haar measures) **442I**, 442J, 442K, 442Xf, 442Xh, 443G, 443Q-443S, 443Xo, 443Yo, *444J*, 444M, 444O, *444Xn*, *447E*, *447F*
modular functional on a lattice **413Xp**; *see also* supermodular (**413P**)
modulation **286C**
monocompact class of sets **413Yd**
Monotone Class Theorem 136B, 312Xc, 313G, 313Xd
Monotone Convergence Theorem *see* B.Levi's theorem (133A)
monotonic function 121D, 222A, 222C, 222Yb, *224D*, **313Xh**; (space of monotonic functions) *463Xg*, *463Xh*
Monte Carlo integration 273J, 273Ya, 465H, 465M
multilinear map **253Xc**
multiplicative identity (in a Banach algebra) 4A6Ab; (in an f-algebra) 353P, 353Yg
multiplicative linear functional on a Banach algebra 445H, 4A6F, 4A6J, 4A6K
multiplicative Riesz homomorphism 352Xm, 353Pd, 361J, 363F, 364R

Nachbin-Kelley theorem 363R, 363Yj
Nadkarni-Becker-Kechris theorem 448P
narrow topology (on a space of measures) **>437J**, 437K-437M, 437O, 437Q-437S, 437Ub, 437V, 437Xi-437Xk, 437Xo, 437Xs, 437Yk, 437Yl, 437Yn, 438Xl, 444Xc, 449Yc, 452Xb, 452Xe, 458Yf, 459F, 459G, 459Xc-459Xe, 495O, 495Xm, 495Xn
natural extension (of an inverse-measure-preserving function) *383Yc*
negligible set **112D**, 131Ca, 214Cb, 344H, 344Yf, 412Jb, 412Xi, 413Xh, 436Yb, 482L; *see also* Haar negligible (**442H**), Lebesgue negligible (**114E**, **115E**), null ideal (**112Db**), universally negligible (**439B**)
neighbourhood (of a point in a topological space) **4A2A**; *see also* base of neighbourhoods (**4A2A**)
neighbourhood gauge **481E**, *481J-481P*, *481Xh*, 482E-482I, 482Xc-482Xf, 482Xj, 482Xk, 482Ya-482Yc, 483A, 483Ya; *see also* uniform metric gauge (**481E**)
network in a topological space 438Ld, 466D, 467Pb, **4A2A**, 4A2Ba; *see also* countable network
Neumann, J. von 341 *notes*; von Neumann-Jankow selection theorem 423O, 423Xg, 423Yd, 424Xh, 433F, 433G
Nikodým *see* Radon-Nikodým
Nirenberg *see* Gagliardo-Nirenberg-Sobolev inequality (473H)
no small subgroups (in 'topological group with no small subgroups') **446E**, 446H-446K, 446M, 446O
non-decreasing sequence of sets **112Ce**
non-increasing sequence of sets **112Cf**
non-measurable set 134B, 134D, 134Xg, 419J
non-principal ultrafilter 464Ca, 464Jc
non-scattered compact set 494B, 494C, 494Xa-494Xc
non-stationary set **4A1C**
norm **2A4B**, 4A4Cc, 4A4Ia; (of a linear operator) **2A4F**, 2A4G, 2A4I; (of a matrix) **262H**, 262Ya; (norm topology) 242Xg, **2A4Bb**; *see also* Fatou norm (**354Da**), Kadec norm (**466C**), Riesz norm (**354Aa**)

normal density function 274A, 283N, 283We, 283Wf
normal distribution **274Ad**, 495Xg; *see also* standard normal (**274A**)
normal distribution function **274Aa**, 274F-274K, 274M, 274Xe, 274Xg
normal filter **4A1Ic**, 4A1J-4A1L
normal random variable **274A**, 274B, 285E, 285Xm, 285Xn, 455C, 456Ab, 456M
normal subgroup 382R, 382Xg, 382Xi, 382Yb, 383Ic, 383Xe, 383Yb; *see also* lattice of normal subgroups
—— —— of a topological group 443R, 443S, 443Xv-443Xx, *443Yc*, 443Yk, *449C*, *493Bc*, 4A5J-4A5L, 4A5S
normal subspace (of a Riesz space) *see* band (**352O**)
normal topological space 411Yc, 412Xg, 412Yd, *414Yg*, 415Yj, 418Xr, 435C, 435Xg, 435Xh, 438Jb, 438Yf, 476Cc, 476Yb, *491Cd*, 491Xs, **>4A2A**, 4A2F-4A2H, 4A2Rc; *see also* perfectly normal (**4A2A**)

order-bounded set (in a partially ordered space) **2A1Ab**, 354Xd, 368Xe
order-bounded linear operator (between Riesz spaces) §355 (**355A**); *see also* order-bounded dual (**356A**), $\mathrm{L}^\sim$ (**355A**)
order-closed set in a partially ordered space **313Da**, 313Fa, 313Id, 313Xb, 313Xc, 314Ya, 316Fb, 323D, *352Oa*, 354Xp, 4A2Re; (ideal in a Boolean algebra) 313Eb, 313Pa, 313Qa, 313Xo, 314Xb, *314Yh*, *316Xh*, *316Xi*, *316Xn*, *316Xu*; (Riesz subspace of a Riesz space) 353J, 354Xp, 375C; (subalgebra of a Boolean algebra) 313E-313G, 314E-314H, 314Ja, 314Xg, 314Xh, *314Yc*, 315Xm, *322Md*, *322Xh*, 323H-323J, *323Yc*, 331E, 331G, 331Yb, 331Yc, *333Bc*, *393Xd*; *see also* sequentially order-closed (**313Db**)
order-complete *see* Dedekind complete (**241Ec**, **314Aa**)
order-continuous bidual Riesz space ($U^{\times\times}$) 356I, 356J, 369D

order-continuous Boolean homomorphism 313L-313N, 313Xl-313Xn, 313Xp, 313Xq, 313Yf, 314Fa, 314G, 314R, 314T, 314Xj, *315Jc*, *315P*, 315Ya, 316Fd, 316Xy, 322Yd, 324E-324G, 324K, 324Ya, *324Ye*, 324Yf, *325Aa*, 325C, 325D, 325H, *326Kf*, 331H, 331J, *332Xm*, *332Xn*, 334Xb, 343B, 344A, 344C, 344E, 344F, *352Xi*, *363Ff*, *364Rc*, 364Yh, *366Xf*, 369Xm, 369Xn, 373Bd, 373U, *375Ya*, 381Ec, 381F, 395Xa, 416W, 491N*see also* regular embedding (**313N**)

order-continuous dual Riesz space ($U^\times$) §356 (**356Ac**), 362A, 363K, *363S*, 365L, 365M, 366D, 366Ya, 366Yc, 367Xf, 368Pc, 368Yj, 369A, 369C, 369D, 369K, 369Q, 369Xa, 369Xe, 369Yh, 371Xe, 375B, *375J*, *375Yd*, 437A, *437C*, 438Xd, *464R*

order-continuous norm (on a Riesz space) **242Yc**, 242Ye, 244Yd, *313Yd*, 326Yj, **354Dc**, 354E, 354N, 354Xi, *354Xj*, 354Xl, 354Xm, 354Xo, 354Xp, 354Yc-354Yh, 355K, 355Yg, 356D, 356M, 356Yg, 356Yi, 365C, 366D, 367E, 367Xu, 367Ym, *367Yq*, 369B, 369Xf, 369Xg, 369Yc-369Yf, 371Xa-371Xc, 371Ya, 374Xe, 374Xg, 374Yb, 376L, 376M, 415Yl, 444Yj, 467N

order-continuous order-preserving function **313Ha**, 313I, 313Xi, 313Yc, *313Yd*, 315D, *315Yg*, 316Fc, *326Kc*, 361Cf, 361Gb, 363Eb, 363Ff, *366Yd*, 367Xb, 367Yb, 385Ya, 386Yb, 386Yc, 392I, 392Xb, 394N, 4A2Ro; *see also* sequentially order-continuous

order-continuous positive linear operator 351Ga, 355G, 355H, 355K, 364Rc, 365P, 366H, 368I, 375Xa, 375Xb, 375Yd; *see also* order-continuous dual (**356A**), order-continuous Riesz homomorphism, $\mathrm{L}^\times$ (**355G**)

order-continuous Riesz homomorphism 327Yb, 351Xc, 352N, 352Oe, 352Rb, 352Ub, 352Xe, *353O*, 353Xc, 356I, 361Je, 355F, 365O, 366H, 367Xh, 368B, 375C, 375Xc, *375Ya*

order-continuous ring homomorphism (between Boolean rings) 361A, 361Je, 365P

order*-convergent sequence in a partially ordered set 245Xc, 356Xd, **367A**, 367B-367K, 367Xa-367Xn, 367Xs-367Xu, 367Ya-367Yk, 367Yq, 368Yg, 368Yh, 369Xq, 376G, 376H, 376Xe, 376Xg, 376Ye, 376Yh, 393Xa, 393Yd, 393Ye; (in $C(X)$) 367L, 367Yh-367Yj; (in $L^0(\mu)$) **245C**, 245K, 245L, 245Xc, 245Xd, 376J; (in $L^0(\mathfrak{A})$) 367Na, 367Q, 367Xq, 367Xt, 367Yg, 367Yp, 368Yi, 372D-372G, 372Xb, 386E, 386F

order-convex set in a partially ordered set **351Xb**; *see also* interval (**4A2A**)

order-dense set in a Boolean algebra **313J**, 313K, 313Xm, *314Yg*, 332A, 412N, 4A3Rc, 4A3S

order-dense Riesz subspace of a Riesz space **352N**, 353A, 353D, 354Ef, 354I, 354Ya, 355F, 355J, *356I*, 363C, 363Xd, 364L, 365F, 365G, 367Ob, 367Ye, 368B-368E, 368G-368I, 368M, 368P, 368S, 368Ya, 368Ye, 369A, 369B, 369C, 369D, 369G, 375D, 375Xc; *see also* quasi-order-dense (**352Na**)

order-dense subalgebra of a Boolean algebra 313O, *313Xj*, 313Xn, *313Ye*, 314I, 314T, 314Xf, 316Xf, 316Xo, 316Xr, *316Yk*, *316Yn*, 323Dc, *363Xd*, *391Xj*

order-isomorphism *312L*

order*-limit *see* order*-convergent (**367A**)

order-preserving function **313H**, 313I, *313La*, 315D, 324Yg, *326Bf*, 361Ce

order topology (on a partially ordered set) 313Xb, 313Xj, 313Yc, 326Yr, 367Yk, 393Xa, 393Yd; (on a totally ordered set) 434Yl, 438Yj, **4A2A**, 4A2R, 4A2S

order unit (in a Riesz space) 243C, **353L**, 353M, 363N, 368Ya; *see also* order-unit norm (**354Ga**), standard order unit (**354Gc**), weak order unit (**353L**)

order-unit norm 354F, 354G (**354Ga**), 354I-354K, 354Yi, 353Yf, 355Xc, 356N, 356O; *see also* M-space (**354Gb**)

ordered set *see* partially ordered set (**2A1Aa**), totally ordered set (**2A1Ac**), well-ordered set (**2A1Ae**)

ordinal **2A1C**, 2A1D-2A1F, 2A1K

ordinate set **252N**, 252Yg, 252Yh

Orlicz norm **369Xd**, 369Xi, 369Xj, 369Xn, 369Yc, 369Yd, 369Ye, 369Yg, 374Xc

Orlicz space **369Xd**, 369Xi, 369Xj, 373Xm

Ornstein's theorem 387I, 387K

orthogonal complement 4A4Je

orthogonal group on $\mathbb{R}^r$ 441Xk, 441Yi, 445Yd

orthogonal matrix **2A6B**, 2A6C

orthogonal projection in Hilbert space 244Nb, 244Yj, 244Yk, 366K

—— in $\mathbb{R}^r$ *475H*, *475P*, *475Q*, *475S*

orthonormal basis 416Yg, 444Yk, 456Yb, **4A4Ja**

orthonormal vectors **2A6B**, 4A4Jg

oscillation of a function **483O**, 483P, 483Q
Ostaszewski's ♣ 439O, **4A1M**, 4A1N
outer automorphism of a group *384G*, *384O*, 384Pb, 384Q, 384Yc, 384Yd, **3A6B**
outer measure §113 (**113A**), 114Xd, **132B**, *132Xg*, 136Ya, 212Ea, *212Xa*, 212Xb, *212Xg*, 213C, 213Xa, 213Xg, 213Xk, 213Ya, 251B, 251Wa, *251Xd*, 254B, *264B*, *264Xa*, *264Ya*, *264Yo*, 393T, 393Xh, 393Yh, 413Xd, 452Xi, *463F*, *463Xa*; *see also* Lebesgue outer measure (**114C**, **115C**), metric outer measure (**264Yc**, **471B**), regular outer measure (**132Xa**), submeasure (**392A**)
—— —— defined from a measure 113Ya, §132 (**132B**), 213C, 213F, 213Xa, 213Xg-213Xj, 213Xk, 213Yd, 214Cd, *215Yc*, 235Ya, 251O, 251R, 251Wk, 251Wm, 251Xm, 251Xo, 252Yh, *254G*, 254L, 254S, 254Xb, 254Xq, 254Yd, 264Fb, 264Ye, 412Ib, 412Jc, 413E-413G, 413Xd, 417Xj, 431E, 431Xd, 432Xf, 471Dc, 471Yb, 451Oc, 451Xk, *464C*, *464D*
outer regular measure 256Xi, **411D**, 411O, 411Pe, 411Xa, 411Yb, 412W, 412Xo-412Xq, 412Yf, 415Xh, 415Yc, *416Yd*, *419C*, 432Xb, 482F, 482Xd, 482Xh
outward-normal function 474E, **474F**, 474H, 474I, 474K, 474M, 474Ya; *see also* canonical outward-normal function (**474G**)

paracompact (topological) space 415Xo, **>4A2A**, 4A2F, 4A2Hb, 4A2Lb; *see also* countably paracompact (**4A2A**)
Parseval's identity **284Qd**
partial derivative *123D*, *252Yj*, 262I, 262J, 262Xh, 262Yb, 262Yc
partial lower density on a measure space **341Dc**, 341N, 447Ab, 447B, 447F-447H
partial order 441Yj; *see also* partially ordered set (**2A1Aa**)
partially ordered linear space **241E**, 241Yg, 326C, §351 (**351A**), 355Xa, 361C, 361G, 362Aa; *see also* Riesz space (**352A**)
partially ordered set **2A1Aa**, 313D, 313F, 313H, 313I, 313Xb, 313Xg, 313Xh, 313Yc, 315C, 315D, 315Xb, *315Yg*, *466G*
partition **1A1J**
partition of unity in a Boolean ring or algebra **311G**, 313K, *313L*, 313Xk, 315E, 315F, 315Xk, 315Xq, *316Xp*, 322E, 332E, 332I, 332Xi, *332Yb*, *352T*, *375H*, *375I*, *381C*, *381D*, *381H*, *381Ia*, *381N*, *381Xf*, *381Xg*, *382Fb*, *383F*, 385C, 385D, 385G-385P, 385R, 385Xa-385Xe, 385Xi, 385Xq, 385Xr, 385Ya-385Yc, 385Yg, *386E*, 386I, 386J, 386L, 386M, *386O*, 386Xd, 386Xe, 388Ib, 392Xg; *see also* Bernoulli partition (**387A**)
pathological submeasure **393Tc**
Peano curve 134Yl-134Yo
perfect measure (space) **342K**, 342L, 342M, 342Xh-342Xo, 343K-343M, 343Xg, 343Xh, 344C, 344I, 344Xb-344Xd, 344Yf, 385V, 416W, **451Ad**, 451C-451G, 451I-451O, 451Xa, 451Xc, 451Xe, 451Xf, 451Xi, 451Xl, 451Yj, 454Ab, 454C-454E, 454G, 454J, 457F, 463F-463I, 463Xl, 494Ya, 495F, 495Xe; *see also* perfect measure property (**454Xd**)
perfect measure property 454I, **454Xd**, 454Xe, 454Xh, 454Yb, 454Yc, 455Ba
perfect Riesz space **356J**, 356K-356M, 356P, 356Xg, 356Xi-356Xk, 356Ye, 356Yg, 365C, 365N, 366D, 369D, 369K, 369Q, 369Ya, 374M, 374Xk, 374Xl, 374Ya, 376P, 376Xl, 437Yj
perfectly normal topological space 412E, 422Xe, 434Xj, 434Yj, 438Jc, **>4A2A**, 4A2Fi, 4A2Hc, 4A2Lc, 4A2Rn, 4A3Kb, 4A3Xd
perimeter **474D**, 475Mb, 475Xj, 475Xk, 475Yc, 484B, 484C, 484Ya, 484Yb; *see also* Cauchy's Perimeter Theorem (475S), locally finite perimeter (**474D**)
perimeter measure 474E-474R (**474F**), 474Xa, 474Ya, 475E-475G
periodic Boolean automorphism **381Ac**, 381H, 381R, 381Xj, 381Xl, 381Xm, 382F, 493Yc
periodic extension of a function on $]-\pi,\pi]$ **282Ae**
permutation group *see* symmetric group
Perron integral 483J
Pettis integrable function **463Ya**, 463Yb, 463Yc
Pettis integral **463Ya**, 464Yb
Pfeffer integrable function **484G**, 484H-484J, 484L, 484O, 484Xe
Pfeffer integral **484G**, 484H, 484N, 484S, 484Xd
Pfeffer's Divergence Theorem 484N

Plancherel Theorem (on Fourier series and transforms of square-integrable functions) 282K, 284O, 284Qd, 445R

Poincaré's inequality 473K

point process *see* Poisson point process (**495E**)

point-countable family of sets **4A2A**, 4A2Dc

point-finite family of sets 438B, 438Xj, 438Ya, 451Yd, **4A2A**, 4A2Fd

point-supported measure **112Bd**, 112Xg, **211K**, 211O, 211Qb, *211Rc*, 211Xb, 211Xf, 213Xo, 234Xc, 215Xr, 256Hb, 343Xi, 416Xb, 419G, 465Yd, 491D, 491Yg

pointwise compact set of functions 462E, 462F, 462J, 462Xd, 462Ya, 463C, 463D, 463F, 463G, *463K*, 463N, 463Xb-463Xe, *463Xg*, 463Xi, 463Xj, 463Xl-463Xn, 463Ya, 463Yc-463Ye, 463Za, 463Zb, 464E, 464Yb, 465Db, *465V*, 465Xg, 465Xj, 465Xm *see also* Eberlein compactum (**467O**)

pointwise convergence (topology on a space of functions) 281Yf, 437Xl, 438P, 438Xp, 438Yh, 438Yi, 443Yn, 454Pa, **462Ab**, 462B, 462E-462H, 462J, 462Xd, 462Ya, 462Yd, 462Z, §463, 464E, 464Yb, 465Cb, 465G, 465Xi, 465Xj, 467Pa, 4A2Nj; *see also* pointwise compact

—- (on an isometry group) 441G, 441Xm-441Xo, 441Ye, 441Yj, 443Xx, 443Ym, 448Xk, 449Xc, 449Xd, 476Xi, 493G, 493J, 493Xc, 493Xf, 493Xg, 493Yb

pointwise convergent (sequence or filter) **462Ab**, 462Xb; *see also* order*-convergent (**245Cb**, **367A**)

pointwise topology *see* pointwise convergence

Poisson distribution 285Q, 285Xo, 455Xc, 455Ye, 495A, 495B, 495D, *495M*, 495Xf; *see also* compound Poisson distribution

Poisson point process **495E**, 495F-495I, 495L-495N, 495P, 495Xa-495Xe, 495Xi-495Xk, 495Xn, 495Xp, 495Yc

Poisson's theorem 285Q

—— *see also* Abel-Poisson kernel (**282Yg**)

Pol, R. 463 *notes*

polar coordinates 263G, 263Xf

polar set **4A4Bh**, 4A4Ch, 4A4Eg

Polish group 424H, 441Xm, 441Xn, 441Yf, 444Ye, 448P, 448Xg, 448Xj, 448Xk, *449G*, 493Xe, 493Xg, **4A5Db**, *4A5Q*

Polish (topological) space 284Ye, 418C, 423Ba, 423I, 423Xa, 424F, 424H, 424Ya, 424Yb, 433Yc, 434Kb, 437Rb, 437Wg, 437Yo, 438Yh, 441Xm, 454B, *454O*, 454Xl, 454Xm, *461Xi*, **4A2A**, 4A2Q, 4A2Ud, 4A3H, 4A3I; *see also* standard Borel space (**424A**)

Pólya's urn scheme 275Xc

polynomial (on $\mathbb{R}^r$) 252Yu

polytope *see* convex polytope (**481O**)

Pontryagin Duality Theorem *see* Duality Theorem (445U)

porous set **223Ye**, **261Yg**, 262L

positive cone 253G, 253Xi, 253Yd, **351C**

positive definite function 283Xt, 285Xr, **445L**, 445M, 445N, 445P, 445Xe-445Xh, 445Xo

positive linear functional (on a Riesz space) 436D, 436H, 436J, 436K, 436Xe, 436Xp, 436Yc

positive linear operator (between partially ordered linear spaces) **351F**, 355B, 355E, 355K, 355Xa, 361G, 367P, 375I-375K, 375Xa, 375Xe, 375Xg, 376Cc, *452H*, *481C*, 495K, 495Lb, 495Xh, 495Yb; *see also* (sequentially) order-continuous positive linear operator, Riesz homomorphism (**351H**)

positive measure everywhere *see* self-supporting (**411Na**)

predictable sequence **276Ec**

purely infinite measurable set **213 notes**
purely non-measurable additive functional **464I**, 464Jc, 464L, 464M, 464P, 464Xa
push-forward measure *see* image measure (**112F**)

quadratic map **372Xn**
quasi-dyadic space **434O**, 434P, 434Q, 434Yh, *434Yi*, 434Yj; *see also* dyadic (**434** *notes*)
quasi-homogeneous measure algebra **374G**, 374H-374M, 374Xl, 374Ye, 394Xg
quasi-order-dense Riesz subspace (of a Riesz space) **352N**, 353A, 353K, 353Ya
quasi-Radon measure (space) 256Ya, 263Ya, **411Ha**, 411Pd, 411Yc, 414Xj, §415, 416A, 416C, 416G, 416R, 416T, 416Xu, 418Hb, 418K, 418Xi, 418Xn, 432E, *434A*, 434H-434J, 434L, *435D*, 436H, 436Xl, 437N, 471Dh, 438G, 439Xh, 441B, 441Xc, §444, 445D, *445Ec*, *445M*, *445Xc*, *445Yf*, 451T, 453Ga, 453J, 453Xd, 453Xg, 453Xh, 454Xj, 454Xk, 456Aa, 456L, 456Xf, 459E, 466A, 466B, 466K, 466Xa-466Xd, 466Xj, 482Xk, 491Mb, 491Xk, 491Xv; *see also* Haar measure (**441D**), Radon measure (**411Hb**)
—— product measure (of finitely many spaces) 417N, **417R**, 417Xv, 418Xf, 418Xh, 436Xh, 441Xi, 443Xb, 443Xp, *444A*, 444N, 444O, 444Ya, 444Yl; (of infinitely many probability spaces) 417O, **417R**, 417Xq, 417Xw, 417Yh, 417Yi, 433H, 441Xi, 443Xq, 453J, 456Xf, 458Xk, 459G; *see also* Radon product measure (**417R**), τ-additive product measure (**417G**)
quasi-simple function **122Yd**, 133Yd
quasi-Stonian topological space **314Yf**
quotient Banach algebra 4A6E
quotient Boolean algebra (or ring) 312K, 312Xk, 313Q, 313Xo, 314C, 314D, 314M, 314N, *314Yd*, 316C, 316D, 316Xh, 316Xi, 316Xn, 316Xu, *316Ye*, 316Yp, 341Xf, 361M, 363Gb, 391Xe, 391Yb, 392Xd, 424Xk, 491I
quotient partially ordered linear space 241Yg, **351J**, 351K, 351Xb; *see also* quotient Riesz space
quotient Riesz space 241Yg, 241Yh, 242Yg, 352J, 352U, 354Yi, 361M, 364C, 364U
quotient ring **3A2F**, 3A2G
quotient topological group 443S, 443Xw-443Xy, 443Yk, 446Ab, 446O, 446P, 447E, 447F, 449Cc, 493Bc, 4A5J-4A5L, 4A5S
quotient topology *245Ba*, *443O-443R*, *443Xs*, *443Yl*

Rademacher's theorem 262Q
Radon, J. 416 *notes*
Radon measure **>411Hb**, 414Xj, §416, 418I, 418L, 418M, 418P, 418Q, 418Xo, 418Xp, 418Xs, 432C-432H, 432Xe, 433Cb, 433D, 433Ha, 433I, 434Ea, 434Fa, 434J, 434Ya, 435B, 435Xa-435Xd, *435Xk*, *435Yb*, 436J, 436K, 436Xn, 436Xp, 437N-437P, 437S, 471F, 471Q, 439Xh, 441Bb, 441E, 441H, 441L, 444Xa, *444Xl*, *444Ye*, *445N*, *445Xb*, 451Ab, 451N, 451Rb, 451S, 451Xk, 451Xn-451Xp, 453Gb, 453K, 453Xf, *453Za*, *453Zb*, 454J, *454K*, 454O, 454Pb, 455D, 455Xe, 455Ye, 456Aa, 457Xf, 458O, 458Xr, 458Yf, 459Xc-459Xe, 462G-462I, 463J, 463K, 463Xk, 466A, 466Xk, 466Xl, 466Ya, 482Xc, 482Xe, 482Xg, 491Ma, 491Xz, 491Yg, 494B, 494C, 494Xa-494Xc, 495N(on $\mathbb{R}$ or $\mathbb{R}^r$) §256 (**256A**), *284R*, 284Yi, 342Jb, 342Xj, 411O, 419C, 419E, 452D, 452O, 452P, 452Xe, 472C-472F, 483Yc; (on $]-\pi,\pi]$) **257Yb**; *see also* complex Radon measure, quasi-Radon measure (**411Ha**), tight Borel measure
Radon-Nikodým derivative **232Hf**, 232Yj, **234B**, 234Ca, 234Yd, *234Yf*, 235Xi, 256J, 257F, 257Xe, 257Xf, 272Xe, 272Yc, 275Ya, 275Yi, 285Dd, 285Xe, 285Ya, *363S*, 452Qa, 458Lb, 458P, 472Ye
Radon-Nikodým theorem 232E-232G, 234G, 235Xk, 242I, *244Yk*, 327D, 365E, 365Xf
Radon probability measure (on $\mathbb{R}$ or $\mathbb{R}^r$) 271B, 271C, 271Xb, 285Aa, 285M, 364Xd, 372Xf, 415Fb; (on other spaces) **256Ye**, 271Ya, 416U, 417Q, 418M, 461H, 461J, 461K, 461N, *461Xc*, 461Xj, *461Yb*

Radon product measure (of finitely many spaces) 256K, 417P, **417R**, 417Xi, 417Xo, 419E, 419Yb, 436Xo, 436Yf, 453Za; (of infinitely many probability spaces) 416U, 417Q, **417R**, 417Xp, 417Xr, *418Na*, 433Ha, 453J, 459Xc-459Xe, 461Ye, 494C, 494Xd

Radon (topological) space **434C**, 434F, 434K, 434Nd, 434Xh, *434Xm*, 434Xp-434Xu, 434Yc, 434Za, 434Zb, 438H, 438R, 438Xn, 438Xp, 438Yi, 439Ca, *439K*, *439P*, 439Xb, 454Pa, 454Xh, 454Xm, 455Ye, 466F, *466H*, 466Xe, 467Pb; *see also* pre-Radon (**434Gc**)

Ramsey's theorem 4A1G, *4A1L*

random variable **271Aa**

rank (of a tree) **421N**, 421O, 421Q, 423Yh

rapidly decreasing test function §284 (**284A**, **284Wa**), 285Dc, 285Xd, 285Ya

rare *see* nowhere dense (**3A3Fa**)

realcompact (topological) space **436Xg**, 439Xm

rearrangement 373Ya; *see also* decreasing rearrangement (**252Yp**, **373C**)

rearrangement-invariant extended Fatou norm **374Eb**, 374F, 374K, *441Yk*

rearrangement-invariant set **374Ea**, 374F, 374M, 374Xk, 374Xl, 374Ye

rectifiable *475 notes*

Recurrence Theorem (for a measure-preserving Boolean homomorphism) 386Xa, 386Xb, 386A

recurrent Boolean homomorphism **381Ag**, 381L, 381O, 381P, 381Q, 381Xh, 381Xi

recursion 2A1B

reduced boundary **474G**, 474N, 474Q, 474R, 474Xb, 474Xc, 474Xd, 475D, 475E, 475Xi; *see also* essential boundary (**475B**)

reduced power of $\mathbb{R}$ **351M**, 351Q, 351Yd, 352L, 368F

reduced product 413Xn

refinable *see* hereditarily weakly θ-refinable (**438K**)

refine **311Gd**, **>4A2A**

refinement **>4A2A**

refinement property *see* σ-refinement property (**448K**)

reflexive Banach space 372A, **3A5G**, 461G, 467Xf

regular cardinal **4A1Aa**, 4A1Bd, 4A1Cc, 4A1I-4A1L

regular conditional probability *see* disintegration (**452E**)

regular embedding of Boolean algebras **313N**

regular measure *see* completion regular (**411Jb**), effectively regular (**491L**), inner regular (**256Ac**, **411B**), outer regular (**411D**)

regular open algebra (of a topological space) 314P-314S (**314Q**), 314Xi, 314Xj, 314Yd, 315Xe, 315Yd, 316Xe, 316Yb, 316Yd, 316Yf, 316Yj, 316Yq, 332Xe, 363Yc, 364U-364W, 364Yh-364Yl, 368Ya, 391Yc, 391Yf, 417Xu; (of $\mathbb{R}$) 316K, 316Yb, 316Yn, 316Yo, 331Xh, 331Yi, 367Yp, 375Xe, 375Yf, 375Z, 376Yi, 391Xd, 392Yb

regular open set **314O**, 314P, 314Q, 417Xu, 443N, *443Yi*, 4A2Eb, 4A3Ra, 4A5Kb

regular operator (between Riesz spaces) 355 *notes*

regular outer measure 132C, **132Xa**, *213C*, 214Hb, 251Xm, 254Xb, 264Fb, 471Dc, 471Yb

regular Souslin scheme **421Xn**, 431Xc

regular topological space **2A5J**, *316Yf*, **>3A3Ab**, 3A3Ba, 3A3De, 414M, 414Xj, 414Ya, 415C, 415D, 415J, 415Qf, 415Rc, *416K*, *418H*, *418Xn*, 422E, 422K, *422Xe*, 434Ib, 434Jc, *462Aa*, *462C*, 476C, 4A2F, 4A2H, 4A2Ja, 4A2N, 4A2Pb; *see also* completely regular (**3A3Ac**)

regularly embedded (subalgebra of a Boolean algebra) **313N**, 313O, 313P, 316Xm, 316Xs, *326Kf*, 367Xi, 491Ke, 491P; (Riesz subspace) **352Ne**, 352Xe, 354Xk, 354Xm, 367F, 368Pa, 368S

regularly enveloped set **491L**

relation 1A1B

relative atom in a Boolean algebra **331A**

relative distribution **458C**, 458D, 458E, 459C, 458Xb, 458Ya, 458Yc, 459C

relative free product of probability algebras **458I**, 458J, 458K, 458M, 458Xe

relative Maharam type of a Boolean algebra over a subalgebra **333A**, 333B, 333C, 333E, 333F, 333Yb

relative product measure **>458Lb**, 458M-458P, 458Xg-458Xr, 458Ye

relatively atomless (Boolean algebra) **331A**, 381P, 386C, 388I, 394Xc
relatively compact set **2A3Na**, 2A3Ob, 3A3De, 3A5M, 4A2Le
relatively countably compact set (in a topological space) *462Aa*, 462Yc, 463I, 463Xf, **4A2A**, 4A2Gf, 4A2Le
relatively independent family (in a measure algebra) **458H**; (of measurable sets) **458Aa**
relatively independent closed subalgebras **458H**, 458Xd
relatively independent random variables **458A**, 458E, 459C, 458Xt, 458Ya, 458Yc, 458Yd, 459C
relatively independent σ-algebras **458A**, 458B, 458F, 458G, *458Xa*, 458Xc, 458Xj, 458Yb, 459B, 459D
relatively invariant measure *441 notes*
relatively Maharam-type-homogeneous **333Ac**, 333Bb
relatively measurable set **121A**
relatively von Neumann transformation **388Da**, 388K, 388Xg, 388Yb, 388Yc, 388Yf
relatively weakly compact set (in a normed space) 247C, **2A5I**, 356Q, 356Xl, *3A5Gb*, 3A5Hb, *3A5Kb*; (in other linear spaces) 376O, 376P, 376Xl
repeated integral §252 (**252A**), 434R, 436F, 436Xo; *see also* Fubini's theorem, Tonelli's theorem
representation (of a group) *see* finite-dimensional representation (**446A**), action (**441A**)
representation of homomorphisms (between Boolean algebras) 344Ya, 344Yd, 364Xr, 424Xk; (between measure algebras) 324A, 324B, 343A, 343B, 343G, 343J, 343M, 343Xc, 343Xf, 343Yd, 344A-344C, 344E-344G, 344Xf, 344Yc, 416W, *451Ab*
residual family **481F**, 481G, 481H, 481K, 481L, 481N, 481O, *481Q*, 481Xb, 481Xc, 481Xf, 481Yb, 484D
resolution of the identity 4A2Fd; *see also* projectional resolution of the identity (**467G**)
'respects coordinates' (said of a lifting) **346A**, 346C, 346E, 346Xg, 346Yc, 346Za
reverse martingale 275K
Riemann-complete integral *see* Henstock integral, symmetric Riemann-complete integral
Riemann integrable function **134K**, 134L, 281Yh, 281Yi, 491Xw
Riemann integral **134K**, 242 *notes*, 363Yi, 436Xm, *481E*, 481I, 481Xe, 491Xj
Riemann-Lebesgue lemma 282E, 445Ka
Riemann sum **481A**
Riesz Convexity Theorem 244 *notes*
Riesz homomorphism (between partially ordered linear spaces) **351H**, 351J, 351L, 351Q, 351Xc, 351Ya, 352G; (between Riesz spaces) 352G-352J, 352U, *352W*, 352Xb, 352Xe, 353Pd, 353Yf, 355Xe, 356Xh, 361Gc, 361J, *361Xg*, 362Xe, 363Ec, 363F, 363Xb, 363Xc, 364R, 365K, 375I, 375J, 375Xg, 375Ya, 376Cc, 436Xg; *see also* order-continuous Riesz homomorphism
Riesz norm **242Xg**, **354A**, 354B, 354D, 354F, 354M, 354Xc-354Xf, 354Xh, 354Yb, 354Yf, 354Yk, 355Xc, 356D, 356Xg, 356Xh, *438Xi*, 466H, 467Yb; *see also* Fatou norm (**354Da**), order-continuous norm (**354Dc**), order-unit norm (**354Ga**)
Riesz Representation Theorem (for positive linear functionals) 436J, 436K
Riesz space (= vector lattice) 231Yc, **241Ed**, 241F, 241Yc, 241Yg, chap. 35 (**352A**), 361Gc, 367C, 367E, 367Xc, 367Yn; *see also* Archimedean Riesz space (§352), Banach lattice (**354Ab**), Riesz norm (**354A**)
Riesz subspace (of a partially ordered linear space) **352I**; (of a Riesz space) 352I, 352J, 352L, 353A, *354O*, *354Rc*, 4A2Jg; *see also* band (**352O**), (quasi-)order-dense Riesz subspace (**352N**), solid linear subspace (**351I**)
right action (of a group on itself) **4A5Ca**, 4A5I
right Haar measure **441D**, 441Xe, 442C, 442E, 442F, 442H, 442I, 442L, 442Xd, 442Xf, 442Xg, 443Xh, 443Xi, 444Yn
right modular function (on a topological group) **442Ib**
right-translation-invariant lifting *447Xa*, *447Ya*
right-translation-invariant metric 441Xn, **4A5Q**
right uniformity (of a topological group) 449B, 449D, 449E, 449H, 449Yc, **>4A5Ha**, 4A5Mb, *4A5Q*
rigid Boolean algebra **384Ha**, *384L*; *see also* nowhere rigid (**384Hb**)
ring §3A2 (**3A2A**); *see also* Boolean ring (**311Aa**)
ring homomorphism **3A2D**, 3A2F-3A2H
ring homomorphism between Boolean rings 311D, *312Xf*, 312Xg, 312Xh, 312Yc, 312Yd, 312Ye, 312Yf, 361A, 361Cc, 361J, 361Xe, 361Xg, 375H

Rokhlin *see* Halmos-Rokhlin-Kakutani lemma (386C)
root (of a Δ-system) **4A1Da**
root algebra (of a Bernoulli shift) **385Q**, 385R, 385S, 387B, 387Ya
rotund *see* locally uniformly rotund (**467A**)

Saks *see* Vitali-Hahn-Saks theorem (246Yg)

separate zero sets **473J**
separated*see* countably separated (**343D**)
separately continuous function *436Ye*, 437Mc, 462I, 463J, 463K, 463Zc, **4A2A**
separation *see* First Separation Theorem, Second Separation Theorem; (in 'countable separation property') *see* σ-interpolation property (**466G**)
separator (for a Boolean automorphism) **382Aa**, 382B-382E, 382I, 382J, 382L, 382M, 382Xa, 382Xd, 382Xl

sequential (topological) space 436F, 436Yd, 436Ye, **4A2A**, 4A2K, 4A2Ld; *see also* Fréchet-Urysohn (**462Aa**)
sequentially closed set **4A2A**
sequentially compact set, topological space 413Ye, 434Za, 462C, *463Cd*, **>4A2A**, 4A2Lf
sequentially continuous function 463B, **4A2A**, 4A2Kd, 4A2Ld
sequentially order-closed set in a partially ordered space **313Db**, 313Xg, 313Yc, 316Fb, 353Ja, 364Xm, 367Yb; *see also* σ-ideal (**313Ec**), σ-subalgebra (**313Ec**)
sequentially order-continuous additive function (on a Boolean algebra) 326Gc, 363Eb
—— —— Boolean homomorphism 313Lc, 313Pb, 313Qb, 313Xq, 313Yb, 314Fb, 314Hb, 314Xc, 314Ye, 315Ya, 316Fd, 324A, 324B, 324Kd, 324Xa, *324Xe*, 324Yc, *326Ff*, *343Ab*, 363Ff, 364G, 364H, 364R, *364Xp*, 364Xv, 364Yc, 364Yf, 364Yn, 365H, 365Xg, 375Ya, 375Ye, 381K, 424Xk
—— —— dual (of a Riesz space)($U_c^\sim$) **356Ab**, 356B, 356D, 356L, 356Xa, 356Xb, 356Xc, 356Xd, 356Xf, 356Ya, 362Ac, 363K, 363S, 437Aa, 437B, 438Xd
—— —— function **313Hb**, 313Ic, 313Xg, 313Yc, 315D, 316Fc, 361Cf, 361Gb, 367Xb, 367Yb, 375Xd, 392H
—— —— positive linear operator or functional 351Gb, 355G, 355I, 361Gb, 363Eb, 363Ff, 364R, 375A, 436A, 436Xi; *see also* sequentially order-continuous dual (**356A**), $\mathsf{L}_c^\sim$ (**355G**)
—— —— Riesz homomorphism 361Jf, 375Ya, 437C-437E, 437Hb, 437Xc, 437Xe, *437Xn*, 437Yd
—— —— ring homomorphism between Boolean rings 361Ac, 361Jf, 375Ka
sequentially smooth dual (of a Riesz subspace of $\mathbb{R}^X$, $U_\sigma^\sim$) **437Aa**, 437B-437E, 437Xa, 437Xc, 437Ya, 437Yd, 437Yi
—— —— linear operator 437D
—— —— positive linear functional **436A**, 436C-436E, 436G, 436Xc, 436Xe, 436Xf, 436Ya, 436Yc; *see also* sequentially smooth dual (**437Aa**)
Shannon-McMillan-Breiman theorem 386E, 386Xc
shift operators (on function spaces based on topological groups) 286C, 443G, 444F, 444Of, 444Xg, 444Xp, 444Yk; *see also* Bernoulli shift (**385Q**)
Shoenfield's Absoluteness Theorem §393 *notes*
Sierpiński Class Theorem *see* Monotone Class Theorem (136B)
signed measure 416Ya, 437B, 437E, 437G, 437I, 444E, 444Sb, 444Xd, 444Yb, 445Yi, 445Yj; *see also* countably additive functional (**231C**), M_σ
signed Baire measure 437E, **437G**
signed Borel measure 437F, **437G**
signed tight Borel measure **437G**; *see* M_t
signed τ-additive Borel measure **437G**; *see* M_τ
simple function §122 (**>122A**), 242M, 361D
simple group 382S, 383I, 383Xb-383Xd
simple product of Boolean algebras §315 (**315A**), 316Xc, 316Xl, 316Xw, 332Xa, 332Xg, 364S, 384Lc, 391Xb, 391Xj
—— of measure algebras **322K**, 323L, 325Xc, 332B, 332Xm, 332Xn, *333H*, *333Ia*, 333K, 333R, 366Xi
simple product property **417Yi**, 419Yc
Sinaĭ's theorem 387E, 387L
singular additive functional **232Ac**, 232I, **232Yg**
singular measures 231Yf, **232Yg**, 362Xa, 461Xl
small subgroups *see* 'no small subgroups' (**446E**)
smooth dual (of a Riesz subspace of $\mathbb{R}^X$)($U_\tau^\sim$) **437Ab**, 437Xa, 437Xc, 437Xd, 437Xq, 437Ya; *see also* M_τ
smooth function (on $\mathbb{R}$ or $\mathbb{R}^r$) **242Xi**, 255Xi, 262Yd-262Yg, **284A**, **284Wa**, **473Bf**, 473D, 473E
smooth positive linear functional **436G**, 436H, 436Xf, 436Xi-436Xl, 439I; *see also* sequentially smooth (**436A**), smooth dual (**437Ab**)
smoothing by convolution 261Ye, 473D, 473E
Sobolev space 282Yf, *473 notes*; *see also* Gagliardo-Nirenberg-Sobolev inequality (473H)
solid hull (of a subset of a Riesz space) 247Xa, **352Ja**
solid set (in a partially ordered linear space) **351I**; (in a Riesz space) *354Xg*
—— linear subspace (of a partially ordered linear space) 351J, 351K, 351Yb; (of a Riesz space) 352J, 353J, 353K, *353N*, 355F, *355J*, *355Yj*, 368Ye, *383J*, *411Xe*, *464K*, *464L*; *see also* band (**352O**)

Sorgenfrey topology on $\mathbb{R}$ **415Xc**, 415Yd, 415Ye, 416Xx, 417Yi, 418Yf, 419Xf, 423Xe, 434Xm, 434Yi, 438Xm, 438Xo, **439Q**, 453Xb, 462Xa, 482Ya
Souslin scheme **421B**
—— set *see* Souslin-F set (**421K**)
—— space *see* analytic space (**423A**)
Souslin-F set 421J, **421K**, 421L, 421Xe, 421Xf, 421Xj, 421Xl, 421Xm, 421Yd, 422H, 422K, 422Ya, 422Yc, 423E, 423O, 423Xf, 423Ye, 431B, 431E, 431Xb, 434Dc, 434Hc, 435G, 435Xk, 436Xg, 466M, 467Xa; σ-algebra generated by Souslin-F sets 423O, 423Xg, 423Xi
Souslin property *see* ccc (**316Ab**)
Souslin's operation §421 (**>421B**), 422Hc, 422Xc, 423E, 423M, 423N, 423Yb, 424Xg, 424Xh, 424Yc, §431, 434Dc, 434Eb, 434Fd, 434Xn, 471Dd, 454Xh
space-filling curve 134Yl
spectral radius (of an element in a Banach algebra) 445Kd, 445Yk, **4A6G**, 4A6I, 4A6K
spectrum (of an M-space) **354L**
sphere, surface measure on 265F-265H, 265Xa-265Xc, 265Xe, 456Xb, 457Xi
—— isometry group of 441Xo
spherical polar coordinates 263Xf, 265F
split interval (= 'double arrow space') **343J**, 343Xf, 343Yc, 344Xf, 412Yb, 419L, 419Xg, 419Xh, 419Yc, 424Yd, 433Xg, 434Ke, 434Yi, 438Qa, 438R, 438Xl, 438Xn, 453Xc, 463Xg, 491Xg
—— line **419Xf**
square-integrable function **244Na**; *see also* $\mathcal{L}^2$
stabilizer subgroup **4A5Bf**
stable set of functions §465 (**465B**); (in L^0) **465O**, 465P-465R; *see also* R-stable (**465S**)
standard Borel space §424 (**>424A**), 433J, 433K, 433Yd, 451L, 452N, 452Xm, 454F, 454H, 454Xg, 455A
standard extension of a countably additive functional 327F, **327G**, 327Xa, 327Xd, 327Xe, 327Yc
standard gamma distribution **455Xe**, 495Xh, 495Xo
standard normal distribution, standard normal random variable **274A**, 456Aa, 456M, 456Xe
standard order unit (in an M-space) **354Gc**, 354H, *354L*, *356N*, 356P, 363Ba, 363Ye
stationary set **4A1C**
Steiner symmetrization 264H, 476 notes
step-function **226Xa**
Stieltjes measure *see* Henstock-Stieltjes integral, Lebesgue-Stieltjes measure (**114Xa**)
Stirling's formula **252Yn**
stochastic *see* doubly stochastic matrix
stochastically independent *see* independent (**272A**, **325L**, **325Xe**)
Stone-Čech compactification 418Yk, 422Ya, 434Yc, 434Yd, 435Yb, 464P, **4A2I**; (of $\mathbb{N}$) 416Yd, 434Yg, 463M
Stone's condition *see* truncated Riesz space (**436B**)
Stone representation of a Boolean ring or algebra 311E, 352 *notes*; *see also* Stone space
Stone space of a Boolean ring or algebra 311E, **311F**, 311I-311K, 311Xg, 311Ya, 312O-312S, 312Xi-312Xk, 312Yc-312Yf, 313C, 313R, 313Xp, 313Yb, 314M, 314S, 314T, 314Yd, 315H, *315Xc*, 316B, 316I, 316Yb, 316Yc, 316Yi, 363A, 363Yf, 381Q, 381Xl, 382Xa, 413Yc, 416Q, 436Xp, 4A2Ib
Stone space of a measure algebra 321J, **321K**, 322N, 322Q, 322Xi, 322Yb, 322Yf, 341O, 341P, 342Jc, 343B, 344A, 344Xe, 346K, 346L, 346Xf, 411P, 414Xs, 415Q, 415R, 416V, 416Xw, 419E, 453M, 453Xa, 453Za, 463Ye, 491Xm
Stone-Weierstrass theorem 281A, 281E, 281G, 281Ya, 281Yg, 4A6B
stopping time **275L**, 275M-275O, 275Xi, 275Xj
straightforward set of tagged partitions **481Ba**, 481G
Strassen's theorem 457D
strategy (in an infinite game) 451U
strictly localizable measure (space) **211E**, 211L, *211N*, 211Xf, *211Ye*, 212G, 213Ha, 213J, 213L, 213O, 213Xa, 213Xh, 213Xn, 213Ye, 214Ia, 214J, 215Xf, *216E*, 234Fd, *235P*, 251N, 251P, 251Xn, 252B, 252D, 252E, 252Ys, *252Yt*, 322Kd, 322N, 322Qb, 322Xi, 325He, 341H, 341K, 342Hb, 343B, *343Xi*, 344C, 344I,

344Xb, 344Xc, *346Xd*, 385V, 412I, *412Yf*, 414J, 414Xt, 415A, 416B, *416W*, 417C, *417Ya*, 451Xa, *452O*, *452R*, 452Yb, *452Yc*, *453E*, *453F*, *453H*, *465Pb*, *465Xp*

strictly positive additive functional (on a Boolean algebra) **391D**, 391J, *391N*, *395Xd*, 417Xu; *see also* chargeable Boolean algebra (**391X**)

—— —— measure (on a topological space) **411N**, 411O, 411Pc, 411Xh, *415E*, *415Fb*, *415Xj*, *416U*, 417M, 417Sc, *417Yd*, *417Yh*, *418Xg*, 433Hb, 435Xj, 441Xc, 441Xh, 441Yj, 442Aa, 443Td, *443Yi*, 444Xm, 453D, 453I, 453J, 463E, 463J, 463Xd, 463Xk

—— —— submeasure (on a Boolean algebra) **392B**, 392F, 392I, 392J, 392Xc, 392Xg, 392Ya, 393Xa, 393Xb, 393Yd, 491Ia

strong law of large numbers 273D, 273H, 273I, 273Xh, 275Yn, 276C, 276F, 276Ye, *276Yg*, 458Yd, 459Xa, 465H, *465M*

strong lifting **453A**, 453B-453D, 453H-453J, 453M, *453N*, 453Xa-453Xe, 453Za; *see also* almost strong lifting (**453A**)

strong measure-algebra topology **323Ae**, 323Xg, 366Yi, 412Yc

strong operator topology 366Yi, 372Yn, 388Yf, **3A5M**

strongly consistent disintegration **452E**, 452G, 452P, 458N, 458Xp, 458Xq, 495I

strongly measure-compact (topological) space **435Xk**

strongly mixing *see* mixing (**372P**)

strongly Prokhorov topological space **437Yo**

subalgebra of a Boolean algebra **312A**, 312B, 312M, 312N, 312Xb, 312Xc, 312Xj, 313Fc, 313G, 313Xd, 313Xe, *315Xn*, 315Xp, *316Xa*, 331E, 331G, 332Xf, 363G, *391Xb*, *391Xf*, *391Xj*, *457A*, *457C*, *457D*; *see also* Boolean-independent subalgebras (**315Xn**), closed subalgebra (**323I**), fixed-point subalgebra (**394Ga**), independent subalgebras (**325L**), order-closed subalgebra, order-dense subalgebra, regularly embedded subalgebra (**313N**),σ-subalgebra (**233A**, **313E**)

subbase (of a topology) **>4A2A**, 4A2Ba, 4A2Fh, 4A2Hc, 4A2Oa, 4A3D, 4A3O

subdivision *see* tagged-partition structure allowing subdivisions (**481G**)

subgroup of a topological group 443Xg, 4A5E, 4A5J; *see also* closed subgroup, compact subgroup, normal subgroup, one-parameter subgroup

subhomomorphism *see* σ-subhomomorphism (**375E**)

sublattice **3A1Ib**

submartingale **275Yf**, 275Yg

submeasure (on a Boolean algebra) §392 (**392A**), 393B, 393T, 393U, 393Xi, 393Yb, 491Aa; *see also* Maharam submeasure (**392G**), outer measure (**113A**), pathological submeasure (**393Tc**), strictly positive submeasure

submodular functional **413Xq**

subring **3A2C**

—— of a Boolean ring 311Xd, 312Xa, 312Xg, 481Hd

subspace measure 113Yb, 214A, **214B**, 214C, 214H, 214I, 214Xb-214Xh, 216Xa, 216Xb, 241Ye, 242Yf, 243Ya, 244Yc, 245Yb, 251P, 251Q, 251Wl, 251Xn, 251Yb, 254La, 254Ye, 264Yf, 322I, 322J, 322Xg, 322Yd, 343H, *343M*, 343Xa, 411Xg, 412O, 412P, 412Xp, *413Xc*, 414K, 414Xn, 414Xp, 415B, 415J, 415Yb, 416R, 416T, 417I, 417Xf, *435Xb*, 471E, 443K, 443Xg, 451Xf, 451Ya, 453E; (on a measurable subset) 131A, **131B**, 131C, 132Xb, 214J, 214K, 214Xa, 214Xi, 241Yf, 247A, 342Ga, 342Ia, 342Xn, 343L, 344J, 344Xa, 344Xe, 344Xf, 414Yc, 415Xd, *415Yh*, 416Xo, 416Xu, 416Xv, 419A, 443F, 451D, 451Yk, *453Dd*, 454Pb, 491Xt, *495Xb*; (integration with respect to a subspace measure) **131D**, 131E-131H, 131Xa-131Xc, *133Dc*, 133Xa, **214D**, 214E-214G, 214M, 214Xm, 412J

subspace of a normed space 2A4C

subspace topology **2A3C**, 2A3J, 3A4Db, 422Gf, *434F*, *434Id*, *434J*, 438La, 462C, 4A2B-4A2D, 4A2F, 4A2Ha, 4A2Kb, 4A2L, 4A2N, 4A2P-4A2S, 4A2Ua, 4A3Ca, 4A3Kd

subspace uniformity **3A4D**, 4A5Ma

subspace σ-algebra **121A**, *214Ce*, *418A*, 424Bd, 424E, 424G, 454Xd, 454Xe, 461Xg, 461Xi, 4A3Ca, 4A3Kd, 4A3Nd, 4A3Xg, 4A3Yb

substitution *see* change of variable in integration

successor cardinal 2A1Fc, 4A1Aa

—— ordinal **2A1Dd**

sum over arbitrary index set 112Bd, 226A
sum of measures **112Xe**, **112Ya**, 212Xe, 212Xh, 212Xi, 212Xj, 212Yd, 212Ye, 334Xb, 334Xd, 415Ya, 416Xd, 437Yj
sum topology *see* disjoint union topology (**4A2A**)
summable family of real numbers **226A**, 226Xf
supermodular functional on a lattice **413P**, 413Xo
support of an additive functional on a Boolean algebra **326Xi**
support of a Boolean homomorphism **381B**, 381G, 381H, 381Xm, 382E, 382I, 382K, 382N, 382P-382R, 384B, *493Yc*
support of a topological measure **256Xf**, 257Xd, **>411N**, 415Qb, 417C, 417E, 417Xq, *434Ha*, *434Ia*, 444Xb, 456D, 456L, 456Xf, *464Xa*, 491Xz; (of a Gaussian distribution) 456D, **456E**, 456L
support of a submeasure on a Boolean algebra **392Xe**
support *see also* bounded support, compact support (**4A2A**)
supported *see* point-supported (**112Bd**)
supporting (element in a Boolean algebra supporting an automorphism) **381Ba**, 381E, 381Jb, 381Qb, 381Sa, 381Xk, 382D, 382N, 382O, 384B; *see also* self-supporting set (**256Xf**, **411Na**), support
supremum **2A1Ab**
—— in a Boolean algebra 313A-313C
surface measure *see* normalized Hausdorff measure (**265A**)
symmetric distribution 272Ye
symmetric difference (in a Boolean algebra) **311G**, 448Xj, 493E
symmetric group 449Xc, 492H, 492I, 493Xc
symmetric measure on a product space 459D, 459E, 459G, 459H, 459Xc, 459Xd, 459Xe, 459Ya
symmetric Riemann-complete integral 481L
symmetric set (in a group) **4A5A**; (in X^n) **465J**
symmetrization *see* Steiner symmetrization

tag **481A**
tagged partition §481 (**481A**)
tagged-partition structure allowing subdivisions **481G**, 481H-481K, 481M-481Q, 481Xb-481Xd, 481Xf, 481Xf, 481Yb, *481Yc*, 482A, 482B, 482E, 482G, 482H, 482K, 484F
Talagrand's measure **464D**, 464E, 464N, 464R, 464Xb, 464Z, 466Xm
Tamanini-Giacomelli theorem 484B, 484Ya
Tarski's theorem §394 *notes*, 449J, 449Ye; *see also* Banach-Tarski paradox
tempered distribution **284 notes**
tempered function §284 (**284D**), 286D
tempered measure **284Yi**
tensor product of linear spaces 253 *notes*, 376Ya-376Yc
tent map **372Xm**, 385Xk, 461Xn
test function 242Xi, 284 *notes*; *see also* rapidly decreasing test function (**284A**)
thick set *see* full outer measure (**132F**)
thin set **484A**, 484E, *484N*
Tietze's theorem 4A2Fd
tight functional **436Xn**, **437Tb**, 437Xq
—— measure 342Xh, 343Yc, 411E, 411Gf, **411Ja**, 411Yb, 412B, 412Sb, 412V, *412Xa*, 412Xe, 412Xl, 412Xn, 412Ye, 414Xj, 416D, 416M, 417C, 417E, 419D, 432B, 432Xc, 433Ca, 434A, *434Gc*, *434Ja*, 434Xb, 435Xb-435Xe, 451M, 451Ra, 471I, 471S, 471Yc, 471Yc; *see also* Radon measure (**411Hb**), signed tight Borel measure (**437G**)
—— *see also* countably tight (**4A2A**), uniformly tight (**285Xj**, **437T**)
Tonelli's theorem 252G, 252H, 252R, 417Hc
topological group chap. 44, §4A5 (**4A5Da**); *see also* abelian topological group, compact Hausdorff group, locally compact group, Polish group (**4A5Db**), unimodular group (**442I**)
topological measure (space) **256A**, **>411A**, 411G, 411Jb, 411N, 411Xg, 411Xh, 411Xj, 411Yb, 411Yc, 414B, 414C, 414E-414K, 414P, 414R, 414Xh, 414Ya, *419H*, *431E*, *432B*, *433A*, *433B*, 434D, *461C*, 463E,

topological semigroup **444Yb**, 449Ya

topological space §2A3 (**2A3A**), §3A3, §4A2

topological vector space *see* linear topological space (**2A5A**)

topology §2A2, §2A3 (**2A3A**); *see also* convergence in measure (**245A**, **367M**), linear space topology (**2A5A**), measure-algebra topology (**323Ab**), order topology (**4A2A**), pointwise convergence (**462Ab**), uniform convergence (**4A2A**)

total order 418Xw; *see also* totally ordered set (**2A1Ac**)

total variation (of an additive functional) **231Yh**; (of a function) *see* variation (**224A**)

totally bounded set (in a metric space) 434L, 441Ya, *448Xi*, 476Ac, 495Yc, **4A2A**; (in a uniform space) 443H, 443I, 443Xk, 443Yd, 463Xb, **4A2A**, 4A2J, 4A5O

totally finite measure algebra **322Ab**, 322Bb, 322C, *322Mb*, *322Qc*, *323Ad*, 323Ca, *324Kb*, *324P*, 327B, *331B*, *331D*, *332M*, *332P*, *332Q*, *333C-333G*, *333J-333N*, *333Q*, *333R*, *366Yh*, *373Xj*, *373Xn*, *373Yb*, 375Fb, 375H, *383Fb*, 383I, 383J, 383Xg, *383Ya*, 386Xa, 384O, *384Xd*, 386A-386D, 386K, 386Xd, 386Xf, 391B, 394R, *395Xa*

totally finite measure (space) **211C**, 211L, *211Xb, 211Xc, 211Xd*, *212G*, *213Ha*, 214Ia, 214Ja, *215Yc*, *232Bd*, *232G*, *243I*, *243Xk*, *245Fd*, *245Xe*, *245Ye*, 246Xi, 246Ya, *322Bb*, *386Xb*, *412Xg*, *441Xe*, *441Xh*, *442Ie*, *471Dh*, 481Xg, 495Xa

totally ordered set *135Ba*, **2A1Ac**, 3A1F

tower (in $\mathcal{P}\mathbb{N}$) 4A1Fb

trace (of a σ-algebra) *see* subspace σ-algebra (**121A**)

transfinite recursion 2A1B

transitive action 442Z, 443T, 443Xz, 448Xi, 476G, 476Yc, **4A5B**

translation-invariant inverse-measure-preserving function 387Xd

translation-invariant lifting **345A**, 345B-345D, 345Ya-345Yc, 346C, **447Aa**, 447I, 447J, *447Xa*, *447Ya*, 453B

translation-invariant lower density 345Xf, 345Ya, **447Ab**, 447B, 447F-447H

translation-invariant measure 114Xf, 115Xd, 134A, 134Ye, 134Yf, 255A, *255Ba*, 255Yn, 345A, 345Xb, 345Ya; *see also* Haar measure (**441D**)

translation-invariant σ-ideal 444Ye

transportation network **4A4N**

transversal (for a Boolean automorphism) **382Ab**, 382B, 382C, 382G-382I, 382L, 382Xa, 382Xk

tree (of sequences) **>421N**

truly continuous additive functional **232Ab**, 232B-232E, 232H, 232I, 232Xa, 232Xb, *232Xf*, 232Xh, 232Ya, 232Ye, *234Ce*, 327C, 362Xh, *363S*, 414D, 438Xb, 444Xl

truncated Riesz subspace of $\mathbb{R}^X$ **436B**, 436C, 436D, 436H

two-sided invariant mean 449Xs

Tychonoff space *see* completely regular (**3A3Ac**)

Tychonoff's theorem 3A3J

type *see* Maharam type (**331F**)

Ulam S. *see* Banach-Ulam problem

ultrafilter 254Yd, **2A1N**, 2A1O, 2A3R, 2A3Se, 351Yd, *3A3De*, *3A3Lc*, 4A1Ia, 4A1K, 4A1L, *4A2Bc*, *4A2Tc*; *see also* non-principal ultrafilter, principal ultrafilter (**2A1N**)

Ultrafilter Theorem 2A1O

uncompleted indefinite-integral measure **234Cc**, 465Ck

uncountable cofinality, cardinal of 4A1A-4A1C

uniferent homomorphism 312F

Uniform Boundedness Theorem 3A5H

uniform convergence, topology of **4A2A**

uniform convergence on compact sets, topology of 454N-454P, 454Xl, 454Xm, 455D, *456Ye*, 4A2Gg, 4A2Oe; *see also* Mackey topology (**4A4F**)

uniform metric gauge **481E**, 481I, 482E, 482Xg

uniform space *2A5F*, §3A4 (**3A4A**), 441Yc, 4A2J

uniformity §3A4 (**3A4A**), 3A5I, 4A2J; (of a linear topological space) 463Xb; *see also* bilateral uniformity (**4A5Hb**), measure-algebra uniformity (**323Ab**), right uniformity (**4A5Ha**), uniform space (**3A4A**)
uniformly complete Riesz space **354Yi**, 354Yk
uniformly continuous function *224Xa*, 255K, **3A4C**, 3A4Ec, 3A4G, *444Xs*, *449B*, *473Da*, 473Ed, 476Ya, 4A2J
uniformly convergent (sequence of functions) **3A3N**, 4A2Jg
uniformly distributed sequence *see* equidistributed (**281Yi**, **491B**)
uniformly exhaustive submeasure **392Bc**, 392C, 392E, 392F, 392J, 392Xc, 393A, 438Ya
uniformly integrable set (in $\mathcal{L}^1$) §246 (**>246A**), 252Yp, 272Yd, 273Na, 274J, 275H, 275Xi, *275Yl*, 276Xd, 276Yb; (in $L^1(\mu)$) §246 (**246A**), 247C, 247D, 247Xe, 253Xd, 354Q; (in an L-space) **354P**, 354Q, 354R, 356O, 356Q, 356Xm, 362E, 362Yf-362Yh, 371Xf; (in $L^1(\mathfrak{A},\bar{\mu})$) 367Xm, 373Xj, 373Xn
uniformly rotund *see* locally uniformly rotund (**467A**)
uniformly smooth (set of linear functionals) 437Ye
uniformly tight (set of linear functionals) **437Ta**, 437Ua, 437Yo;(set of measures) **285Xj**, 285Xk, **285Ye**, 285Yf, **437Tb**, 437U, 437V, 437Xr-437Xt, 437Yf, 437Ym, 452D, 452Xd
unimodular topological group **442I**, *442Xf*, *442Xg*, 442Yb, *443Ag*, 443Xw-443Xy, 443Yk, *443Yn*, 444R, 444Yh, *449Xe*, 449Xl, 449Xo
unit ball in $\mathbb{R}^r$ 252Q
unital (Banach) algebra **4A6Ab**, 4A6C-4A6E, 4A6I, 4A6J, 4A6L-4A6N
universal Gaussian distribution **456F**, 456G, 456H, 456Yb, 456Yc
universal mapping theorems 253F, 254G, 315B, 315I, 315 *notes*, 325C, 325H, 325J, 369Xk
universally complete Riesz space *see* laterally complete (**368L**)
universally measurable set 432A, **>434D**, 434Eb, 434F, 434S, 434T, 434Xc, 434Xd, 434Xf, 434Xg, 434Xy, 434Yc, 434Yb, 438Xj, 439Xd, 439Xl, 444Ye, 451Xi, 454Xi; *see also* $\Sigma_{\rm um}$ (**434Dc**)
—— —— function **>434D**, 434S, 434T, 437Xe, 437Yd, 463Zc, 466Xi
—— —— *see also* universally Radon-measurable (**434E**)
universally negligible topological space **439B**, 439C, 439F, 439G, 439Xb-439Xh, 439Ya-439Yd; *see also* universally τ-negligible (**439Xh**)
universally Radon-measurable set **>434E**, 434Fc, 434J, 434Xe-434Xg, 434Xi, 434Yd, 437Ib; *see also* $\Sigma_{\rm uRm}$ (**434Eb**)
—— —— function **434Ec**, 437Ib, 466L
universally τ-negligible topological space **439Xh**, 439Yd
up-crossing 275E, 275F
upper asymptotic density **491A**, 491I, 491Xb, 491Xd
upper derivate of a real function **483H**, 483J, 483Xm
upper envelope *see* $\mathrm{upr}(a,\mathfrak{C})$ (**314V**)
upper integral **133I**, 133J, 133K, 133Xe, 133Yf, 135H, 214Xm, 252Ye, 252Yh, 252Yi, 253J, 253K, 463Xj, *464Ab*, *464H*, *464Kb*, *465M*, *465Xn*
upper Riemann integral **134Ka**
upper semi-continuous function 414A, 471Xf, 476D, 476E, **4A2A**, 4A2Bd
—— —— relation *422A*
upwards-directed partially ordered set **2A1Ab**
Urysohn's lemma 4A2Fd
—— *see also* Fréchet-Urysohn (**462Aa**)
usual measure on $\{0,1\}^I$ **254J**; *see under* $\{0,1\}^I$
usual measure on $[0,1]^I$ **416U**; *see under* $[0,1]^I$
